In the *Vital Parts*

Bottlenecks

Editors of technical journals are taking up the cudgels on the side of those who argue that science and invention produce employment, by citing definite cases. We can't see the real necessity of proving that sort of thing to anyone who is intelligent enough to read a technical journal. Such editorials mostly waste their sweetness on the desert air.

However, if a really good case of a meritorious invention is needed, one cited by Holbrook in the June 3, *Saturday Evening Post,* fills the bill. He describes a trencher whose demountable parts can be packed on men's backs to the vicinity of a forest fire, set up and the trencher operated to produce a fire-stopping trench by mechanically hammering off the loose stuff from the forest floor. The machine, run by one man, is said to trench a mile an hour, or as fast as 300 men could clear such a trench. And when forest rangers commandeer workers for fire fighting, the workers don't take a W.P.A. pace, either. That the availability of such equipment in summer will save the all-winter jobs of many loggers is self-evident.

Other editors and writers take the benefits of technical progress as beyond the need of discussion and go on from there to the agreement that we need some new invention to produce something everyone will class as a necessity, once it is available. They clamor for invention, as though inventions can be produced on short order. Some argue on a purely statistical basis, citing figures to show that the number of patents per capita is not increasing as fast in the U. S. as in some other countries so we're going to the dogs on this count alone. In the first place, the patent offices of some countries merely act as recorders advancing practically every application to patent status and leaving patentability entirely to the courts, while others allow patenting of very obvious combinations of old elements, so that the number of patents issued is no real indicator of the number of true inventions. In the second place, the basic patents relating to any real industry-building development are very probably on the books already, if indeed, they are not expired or close to expiration, since there is a long period of incubation in such things. To ask for some new invention to save the immediate situation is to be a bit naïve.

Perhaps the type of invention to produce relatively rapid results might be exemplified by Canadian Patent 381630, "Appareil à faire des fossettes"—i.e. —a dimple-making apparatus. This works in a Goldbergian sequence: Girl makes dimples, dimples make her irresistible, boy can't delay marriage, new responsibilities force him to show enough ingenuity to find way to make living, he leaves ranks of unemployed, buys refrigerator, car, baby carriage, etc. Multiply by lots of dimples, girls, refrigerators, etc. and there you are.

If we stick to technology for our solution, why not focus attention on the bottlenecks that make things everybody already wants, too expensive for them to buy, or too inefficient or too short lived to justify the purchase? To cite again one of our favorite cases of technical improvement, the automobile tire, suppose everything else about the automobile could be made as it is today, but no one had been able to make a better tire than those of the days when one cost $25.00 and lasted 5000 miles. How many cars would be built this year?

We suspect that a good many industries are in the situation the car would be in without a tire to match the other parts in cost and service, without recognizing that a bottleneck exists. If some certain limitation that we have accepted heretofore as inevitable in the method of production or in the properties of the product could be removed over night, every operating man and every salesman could start out in the morning, certain that now he could go places.

If research activity is directed at these bottlenecks, some of them can be widened, and if enough are widened, that would turn the trick better than any hypothetical wonder-working invention.—H. W. G.

It Ain't Gwine to Rain No Mo'?

The last report of the Monsanto Chemical Co. remarks that orders have been coming in at a rate which suggests over-stocking, hence a corresponding diminution of demand is to be expected later. In other words, don't count on future dividends

Diamonds in Finding and Fabricating Metals

by E. D. LUCAS, Jr.

423 *E. Union Boulevard, Bethlehem, Pa.*

IT MAY SEEM LIKE FANTASY to conjure up a connection between the crown of the Maharajah of Indore and a modern American automobile plant. But the Indian potentate's crown gleams brilliantly with its display of 73 diamonds, while the workaday cousins of those gems are grinding, boring and cutting in steel mills, in wire mills for copper, steel and tungsten, in automotive plants and machine shops.

Throughout industry, diamonds are no symbol of luxury; rather, they are a useful material, the hardest, natural or synthetic, known to man. Industrial diamonds, which may come from the same mine as the pure gem stones which sparkle from behind the jeweler's plate glass window, are destined literally to wear away their lives in service. About one-half of the world's diamond production is used for utility alone, in mining and manufacturing operations all over the world.

The vast majority of these workaday industrial diamonds are used in connection with metals and alloys. Diamonds are used in the prospectors' drills which locate ore mines. Diamonds are used for drawing fine, hard, precise wire. Diamonds are used in grinding, cutting and finishing operations on automobile motors, optical instruments and thousands of other products made of metals and alloys. Diamonds are indeed the crown jewels of industry.

Three Types Used Industrially

Three types of diamonds are used industrially. Gem stones are in the minority, and are clear and crystallized, like the "headlights" worn by Diamond Jim Brady. Bortz are the most common and popular industrial diamonds; they are round and imperfectly crystallized stones, with a radiate or confused crystalline structure. Carbonados, the third main group, are black diamonds, clusters of small diamond crystals in one hard lump without any cleavage planes. Carbonados are obtained in quantity only from the State of Bahia, Brazil, where they are found in streams and gravel beds along with gem stones. Bortz are mined principally in South Africa, although Brazil, the East Indies, India and other countries are also diamond suppliers.

These main categories of industrial diamonds, gem stones, bortz, and carbonados, are further subdivided into smaller classes. For instance, particularly fine bortz of a round form composed of crystals radiating from a common center are known as ballas.

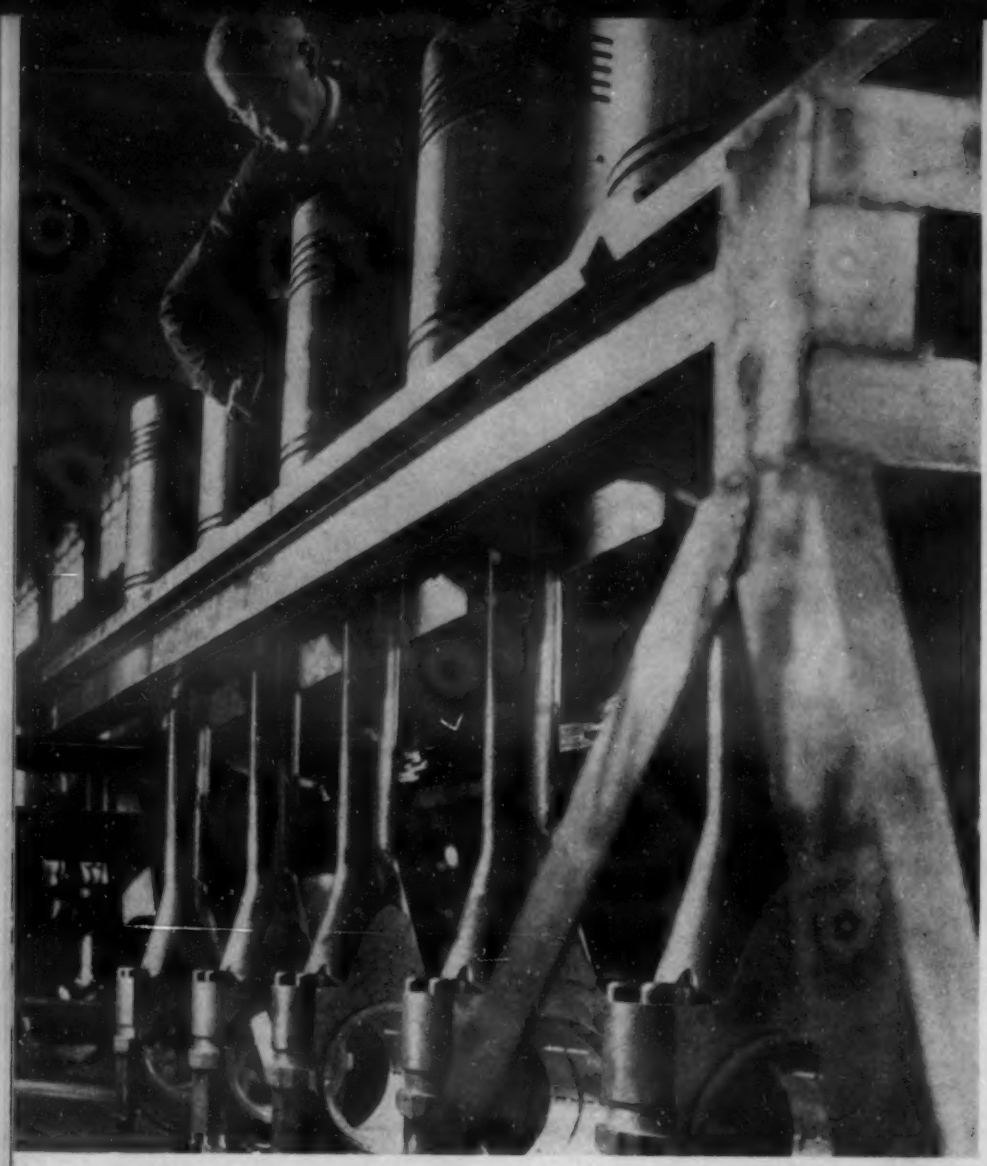
Diamonds are a useful prospector's tool. Right now, a thousand miles north of the copper mines at Butte, Mont., which were explored with diamond drills, there is a modern gold rush around the cabin town of Yellowknife on Great Slave Lake. There, in Canada's far Northwest Territory, the surface findings showed gold quartz so rich that it assayed half a million dollars to the ton. But in this remote wasteland, reached only by airplane or by a difficult 500-mile boat trip from the nearest railroad, it was important to know how deep and how rich were the gold strikes. Diamond drills were shipped by plane to tell the answer.

These diamond core drills consist of diamond bits, rings of a special alloy into which are set a hundred or more small bortz diamonds, attached to the ends of tubular steel drills. The drills are rotated by power, and the diamond core bits cut through quartz and granite, rock tough enough to crumple the hardest steel, bringing back samples or cores of the strata below. Then mining engineers can analyze these samples to discover whether a strike is just a surface outcrop or a rich, deep vein of ore.

In the Mining Industry

At Yellowknife the results were so favorable that 30 mining and prospecting companies are working in this area, thanks to the assayed samples from diamond core drills.

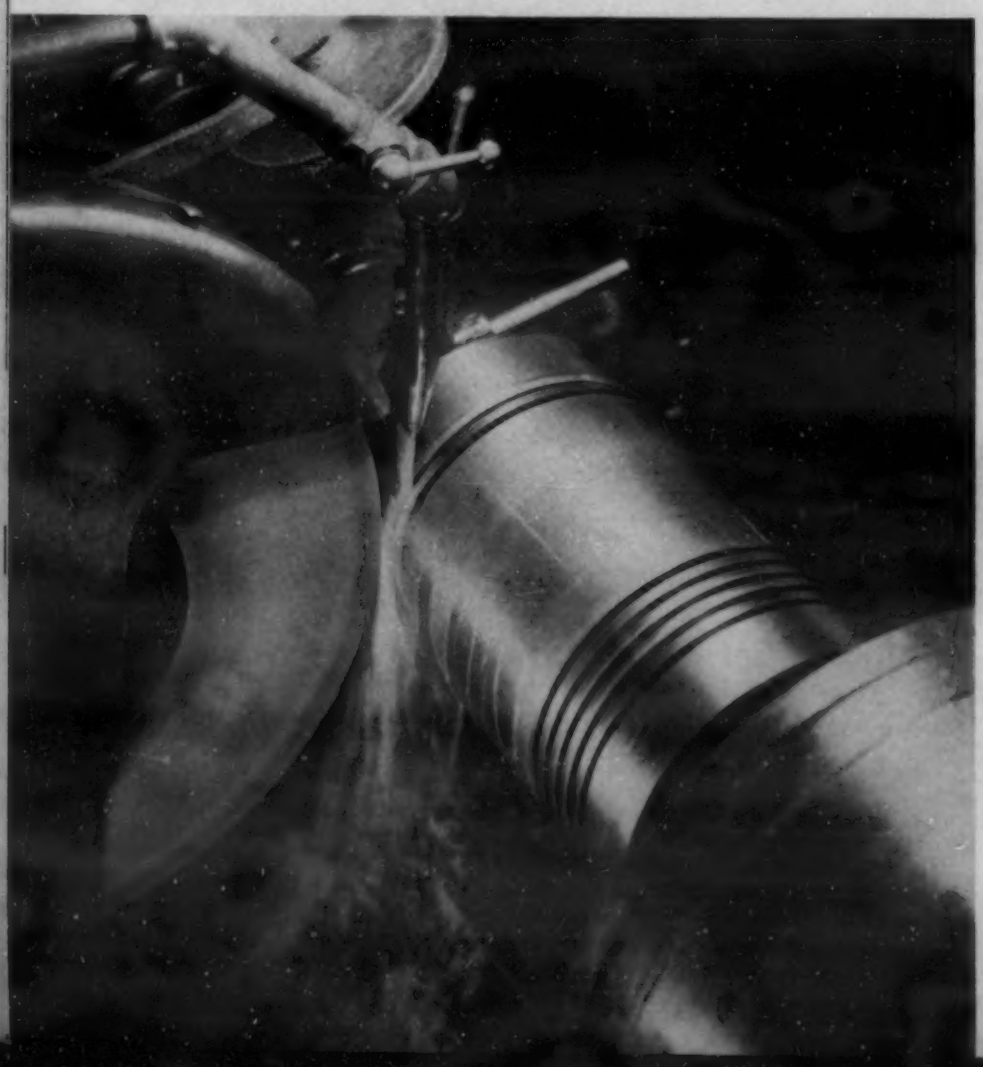
In the province of Ontario, statistics have been collected on the use of diamond drills. They show



The efficiency of a Diesel engine depends on the accuracy of the machining of the cylinder block. Diamond sharpeners keep the cylinder boring tools keen and accurate.

that in this area alone about 350 miles of drill holes were bored in 1936 with diamond core drills. Drillers used about 100,000 carats of industrial diamonds, largely bortz such as the "Finehards" supplied by J. K. Smit & Sons, varying in size from 1/30 to 1/4 carat. A typical mine explored with diamond drills is that of Falconbridge Nickel, near Sudbury, Ontario. There the ground was covered with gravel to a depth of 60 ft. About 90 holes were bored, for a total length of 18,000 ft., outlining an ore zone 7,000 ft. in length. With no information other than that provided by the cores brought up by the diamond drills, a shaft was sunk and a successfully producing mine brought in.

One of the most exciting mine rescues in recent years was made possible because of a diamond drill. In the spring of 1935, three men were trapped far underground in the Moose River Gold Mine cave-in. A diamond drill was used to sink a small shaft for sending down food, drink and medicine. This shaft was drilled so accurately that it came within 6 ft. of the men, over 150 ft. below; and the supplies sent down to them kept them alive until the rescuers reached them.



In Precision Tools

Diamonds were used in mining many decades ago, but the use of diamonds in the precision tools used in machine shops dates back only to about 1914. In the war years, Liberty motors for airplanes became such a necessity that diamond boring of metals was developed in a more or less crude way to fill the gap left by ordinary machine tools, where tolerances required the precision that only diamond-tipped tools can give. Liberty motors had seven bearings, and to align them was a tremendous problem. Various types of bars and reamers were used with no great success. It was probably Nordyke-Marmon who first conceived the idea of using a diamond tool to finish-bore these seven bearings. Later Packard and Cadillac adopted this diamond method for the motors which

Inspection of Diesel engine pistons and connecting rods after a new engine has been given a test run in the plant of a leading Diesel builder. Diamonds help to make these pistons set perfectly. (Courtesy: Gulf Refining Co., Pittsburgh.)

A Diesel engine piston is being ground for accurate measurement and smooth finish. This grinding wheel takes off only a small cut. This and other grinding wheels are trued with the aid of diamonds. Some grinders use a lap of diamond dust and oil for cutting. (Courtesy: Gulf Refining Co., Pittsburgh.)

they were building. Nordyke-Marmon continued to use shaped diamond tools for machining auto parts after 1918, and both Cadillac and Packard had machines designed for their diamond boring operations. At present all the principal automotive manufacturers use diamond-tipped tools.

These shaped diamond tools consist of a diamond set in a metal holder. The diamond point is carefully cut by a skilled craftsman. First, the shape of the diamond is magnified up to 75 times by means of a projectograph, and this instrument is again used for checking the final dimensions, included angle and radius of the stone. Then the diamond cutter cuts or polishes the table or flat part of the stone. The proper undercuts are next cut or polished on the right and left sides of the stone, to give the diamond the desired included angle and the proper clearance on the cutting edge. The radius or rounded cutting edge is formed and polished as the final step.

In the Automobile Industry

In a typical automobile plant, these shaped diamonds set in metal holders are used to finish wrist pin holes in pistons, to ream bearing ends of connecting rods, and to turn aluminum alloy pistons and other parts. The Ford Motor Co., for instance, regularly uses diamond-tipped tools for boring wrist pin holes in rough and finished pistons, for boring bearing holes on both large and small ends of connecting rods, and for turning pistons.

In making Plymouths, like other automobiles, hundreds of shaped diamond tools are used. To keep track of these many diamond tools, there is a special "diamond clerk" who checks them in and out, as the tools are borrowed for precision drilling, fine surface finishing, truing other tools, boring wrist pin holes, etc.

Another familiar use of industrial diamonds is found in the Studebaker plant at South Bend, Indiana, where stones of two and one-half carats are regularly used to dress down the abrasive wheels used in grinding crankshafts. Here indeed is one of the most widespread applications of the industrial diamond, because in factories of all sorts in every country, diamonds are used for truing grinding wheels. In this use, about 85 per cent of the diamonds employed are of the bortz type, while the remaining 15 per cent are carbonados.

Both shaped diamond tools and resinoid wheels impregnated with diamond dust are used in truing grinding wheels. The shaped diamond tool usually adapted to this purpose has a rounded cutting face which is made to travel across the wheel face at a very slow and uniform rate. By combining a light cut and a slow traverse, the diamond point keeps fairly cool and its life is prolonged. By changing the depth of the cut or the speed of the diamond

in traversing the face, an operator can easily make the wheel surface either rough or smooth.

In Machine Tools

Diamonds have several advantages as points for machine tools. Whereas ordinary cutting or grinding tools soon wear down, shaped diamond tools consistently set amazing records of performance because diamonds are by far the hardest substance known. In one large automobile plant, for example, a shaped diamond has been used to ream over 19,000 bearing holes. The diamond has been reshaped and reset several times, and is still doing precision cutting. Another automotive manufacturer reported a run with a single diamond tool which machined wrist pin holes on over 200,000 pistons before the diamond was chipped and needed relapping.

A second reason why industrial diamonds are becoming increasingly popular, especially among those who have to bore, finish or grind metals, is that a diamond cutting edge gives a precision in boring or turning operations that no other substance will give. Diamond-tipped tools are suited to mass production, the precise finishing of thousands of identical parts. The Bausch & Lomb Optical Co., maker of precision instruments, is a large user of industrial diamonds, because its production men find that a shaped diamond tool, properly handled, will machine several hundred thousand parts without need for relapping.

Diamond tools have been used to turn all sorts of metals, from soft babbitt to hard bronze, with accuracy often to one ten-thousandth of an inch. Aluminum alloy pistons were machined with great difficulty before shaped diamond tools were used to turn them. Diamond-tipped tools may occasionally chip after limited use, but only when proper precautions have not been observed as to the holder, the set of the tool, the operating speed and the coolant.

In Wire Drawing

Precision is the chief factor in another application of diamonds in the metal-working industries—wire drawing. About one-fifth of all industrial diamonds are used as dies for drawing fine wire of copper, steel, tungsten, osmium and tantalum. This use dates back to the first patent on a diamond die, issued to Brokedo in England in 1819. The stones used are cleavage plates or thin crystals, the so-called "flats," and ballas. Their weight varies from ½ to 10 carats. In each stone is drilled a hole at dead center. The hole is tapered at each end; it is started with a diamond point and is finished with a steel drill fed with diamond dust. When the hole is completed the diamond plate is mounted in a metal disc, and then wire is drawn through a series of such dies until it is reduced to the proper diameter.

When the aperture of one of these diamond dies grows too large, after much wear, it is redrilled to draw the next larger gage of wire. Diamond dies last a long time, however; enough 20-gage copper wire to go around the world 25 times can be run through a diamond die before the hole suffers any measurable enlargement. And diamond dies must be precise, for some of the filament wires drawn are only 0.0004 in. (0.01 mm.) in diameter; a rod of tungsten 3 in. long and ⅜ in. in diameter, is transformed by diamond drawing into a gossamer filament 58 miles long!

Heavier gages of wire are often drawn through dies of the hard synthetic material, tungsten carbide. When these dies develop worn areas or rings after hard service, another form of industrial diamond, diamond dust, is used with oil as a lapping agent in connection with grinding tools which smooth out the worn spots. These diamond-lapped grinding tools, as well as metal saws which are fed with diamond dust in an oil bath or have the gem dust beaten into the cutting edges, find many uses throughout industry. Diamond-lapped saws, for instance, are often used to cut stainless steel bars.

In Hardness Testers

It is not surprising that a diamond, which lends itself so readily to precise work throughout the metal-fabricating industries, finds a useful place in metallurgical laboratories. Hardness testers, Rockwell, Vickers and others, employ the principle of a machine which forces a diamond point into the metal under examination. A dial on the instrument gives a reading for the depth of penetration of the diamond point, from which in turn may be calculated the hardness of the metal tested. The Nestor Johnson Mfg. Co. has capitalized on this test, which it uses to determine the hardness of steel runners of ice skates, as an effective advertisement, while the American Safety Razor Co. has also advertised its product as diamond-tested.

Diamonds are used to scratch designs on metal cigarette and vanity cases. Diamonds serve as nozzles on oil-burning furnaces and Diesel engine injectors. A new machine for boring cylinders of Diesel engines includes a diamond sharpening disc for keeping a keen edge on the cylinder cutters. Diamond-tipped tools are used to finish bearings for electrical motors, automotive valves, bronze bushings for refrigerators and the precise parts of watches, cameras and all sorts of precision instruments and apparatus, large and small.

As metals and alloys are manufactured in continually more efficient and attractive forms, industrial diamonds are playing their increasingly important role in helping to find and fabricate metals.

Mounting of the 200-Inch Telescope

•

A Welded Structure

PART 2 · CONCLUDED FROM NOVEMBER

by Frank Fredericks and N. L. Mochel

Resident Engineer for California Institute of Technology, and Metallurgical Engineer Respectively, Westinghouse Electric & Mfg. Co., South Philadelphia Works, Lester, Pa.

The most spectacular piece of fabrication in the whole telescope mounting is no doubt the horseshoe girder or "horseshoe", having a total weight of 155 tons not including the counterweights to be filled in later. A view of the floor assembly, with the north side up, is shown in Fig. 18.

It is constructed in three sections with machined joints, the bolts to be shrunk in with the aid of electric heaters. The two outer sections, or "horns" are provided with ring faces or flanges, to which are bolted the tubular yoke sections. There are also faces for the attachment of the 2-ft. tubular struts shown in Fig. 2. The outer or track plates were 4½ in. in thickness to allow for machining later, and were received from the mill very closely formed to the required radius. The inner plates are 4 in. thick.

Fig. 19 shows a pair of these plates set up on edge around a web plate. This latter was cut with a radiograph machine, with a single bevel all around, facing the outside. Fig. 20 shows an early stage of fabrication of this horn section, while Figs. 21 and 22 show a later stage of the same piece and the center section respectively.

The arrangement of the 1⅛-in. transverse stiffening ribs along the inside of the track plate calls for some comment. Referring to Fig. 20 these

Fig. 18. Assembly of Horseshoe Bearing.

Fig. 19. West Horn of Horseshoe—First Step in Fabrication.

plates are spaced about 12-in. apart by short sections of the central rib. In making this assembly, the cumulative pull of the welds between the rib sections and diaphragms had to be guarded against. This was done by first tacking them in place and to each other in groups, removing each group for welding on the floor and then replacing it for final welding inside the track plate. By proceeding in this way, the final out-of-roundness of the three horseshoe sections when bolted together as in Fig. 18, before machining the circumference, was found to be not more than plus or minus 3/16-in. on a diameter of 46 ft.

All the diaphragms or stiffening plates in the horseshoe sections were planed to an exact width so as to obtain a good bearing against the cover plates. This obviates the filling in of gaps which would be left if the plates were torch cut and consequently varied in width.

The end panels of the three sections are identical. A close-up view is shown in Fig. 23, and one of them is also clearly seen in Fig. 22. Each panel or frame consists of two long 3-in. plates, a 6-in. and a 7-in. slab, with a ¾-in. plate in the center. It was originally intended to weld these parts one by one into the main structure, and single bevel welds were shown on the drawing to connect the ¾-in. web plate to the frame. However, it was found more desirable to complete these panels as separate subunits. In making the above bevel welds, shown in Fig. 24 (a), some trouble was experienced in the bellying of the web plate and consequent cracking along the edges. The web plates were then changed to call for double fillet welds as shown in Fig. 24 (b).

All the inside welding was completed with the north side cover plate left off. Braces of 4-in. double extra heavy pipe were temporarily welded across the edges of the inner and outer plates to hold the structure during welding and the first annealing operation, as shown in Figs. 21 and 22.

The horseshoe sections, like all other parts of the mounting, were to be thoroughly sandblasted and painted inside and out. In order to avoid the difficulty and danger of sandblasting inside these hollow structures after completion, the plan was adopted of cleaning all inside surfaces after the first anneal, while one side was still open, and coating them

Fig. 20. West Horn of Horseshoe—Assembling Stiffening Diaphragms.

with a high temperature resistant aluminum paint before attaching the cover plate. All inside welding was then done with the aid of a shiphold ventilator for withdrawing the fumes from the operator. After the second anneal, very little cleaning with a grinding wheel or revolving wire brush was found to be necessary.

The arrangement of the welds joining the 4½-in. track plate to the end panel or connecting flange is seen in Fig. 25 (a) and Fig. 26. The first detail (a) shows the method employed at the start, the inside weld being made first. Both sides were welded in a vertical position. During preliminary planing of the joint faces, later on, it was found that there had been a lack of penetration and some cracking in a number of places in the large outer welds. To play safe, therefore, the deposited metal was removed entirely by milling, as in Fig. 25 (b). Each section was then set in a pit to bring the face horizontal for downhand welding. The metal was deposited rapidly, building up short sections at a time and peening each layer. Heat was applied with gas torches around the work and maintained until the sections were once more placed in the annealing furnace.

After machining the end faces, the new welds presented a very homogeneous appearance, and etching showed a total absence of imperfections.

Fig. 21. West Horn of Horseshoe—Ready for First Anneal.

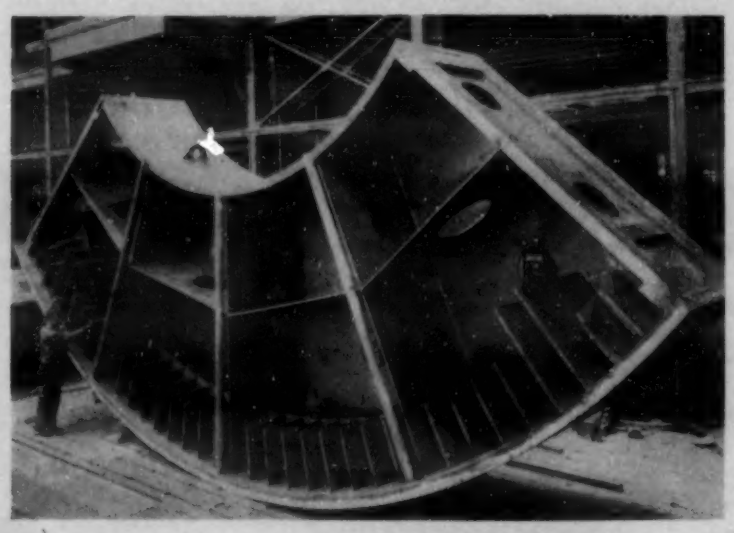


Fig. 22. Center Section of Horseshoe—Ready for First Anneal.

Fig. 23. End Panel of Horseshoe Sections.

The upper and lower sections of the side members of the yoke are in the form of tubes 10 ft. 6 in. in diameter and approximately 17 and 19 ft. long respectively. They are connected by internal flanges 2½ in. thick. One of these tubes is shown in Fig. 27. Each is formed of two rolled shells of 1-in. plate with a longitudinal and a circumferential seam welded in an automatic welding machine. The flanges were first rough turned for the welding groove as shown in Fig. 28. The original intention was to make the outside weld only. It was found however that the contraction of the weld had the effect of dishing the flange quite appreciably. The inside fillet weld shown in the illustration was therefore made first to counteract this effect.

The center section of the yoke is in the form of a similar flanged tube or 1-in. plate, 10 ft. long, into which is set a transverse cylinder 5 ft. in diameter, with reinforcing plates around the opening. Into this transverse hole will be inserted the ball bearing unit for the declination axis, about which the telescope tube rotates in the yoke.

The particular center section at the west side of the yoke, which is shown in Fig. 29, is provided with a large bracket which will take the thrust of the worm driving a 14-ft. worm gear for rotating

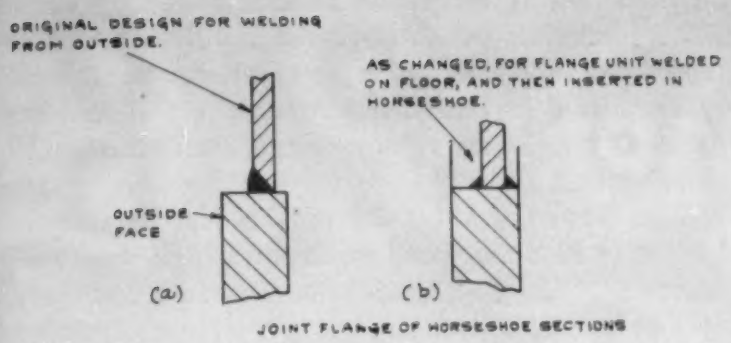

Fig. 24. Welds on Horseshoe End Panels.

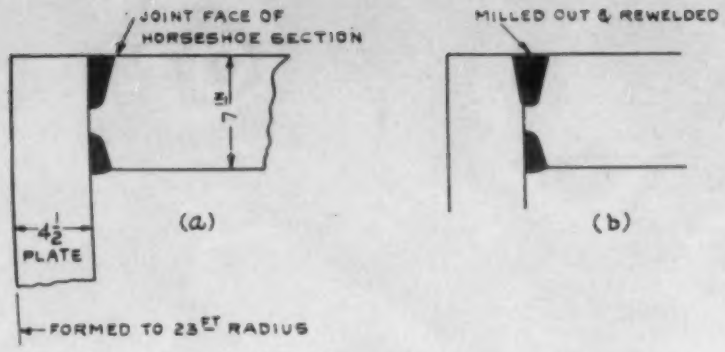

Fig. 25. Main Welds of End Panels to Track Plates of Horseshoe Sections.

the telescope tube. This piece is noteworthy for the number of irregularly shaped plates composing it. It is a good illustration of the versatility of the welding art, in conjunction with torch cutting, in building up pieces of awkward shape without spending a great deal of time in the making of drawings of the parts. In this particular case, the individual plates were carefully projected on the drawing board, taking their thickness into account. However, a few trial templates showed that they were not very reliable, due probably to slight misplacements and changes of shape in the parts already welded. Each plate was therefore made to a sheet metal template trimmed to the required shape as the work proceeded. Most of the bracket plates were attached to the main piece by bevel welds from the outside.

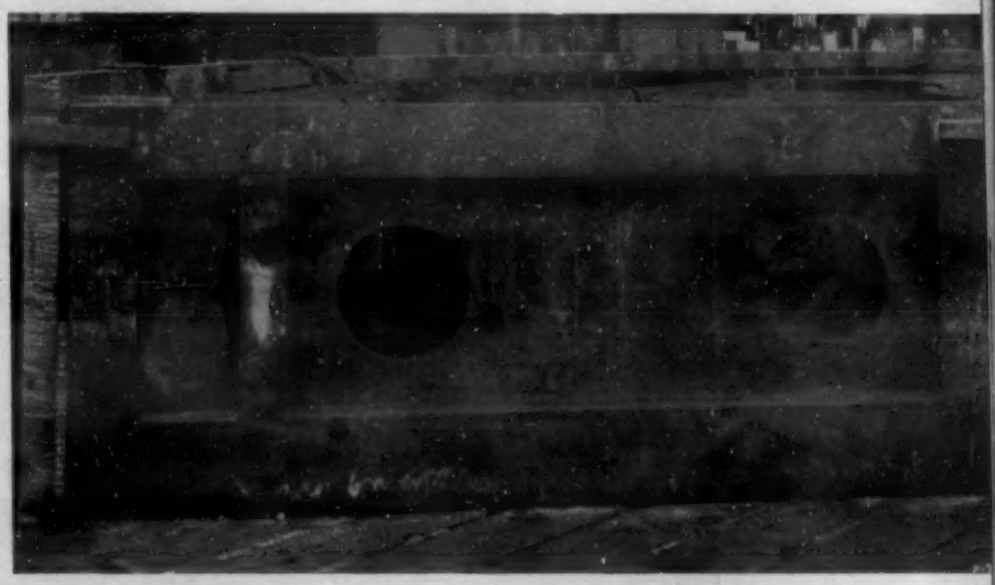
The south cross member of the yoke is a box structure 46 ft. long having two large flanges for attachment of the tubular yoke sections and four flanged nozzles to which the brace pipes are attached. Fig. 30 shows the completed structure on the planer. Its finished weight is 86,000 lbs.

The center unit of this piece is shown in Fig. 31; comprising two 4-in. plates, a central shell, and various stiffening diaphragms of 7/8-in. plate. Here again some ingenuity was required in arranging the sequence of assembly of the plates in order to do all the welding from the outside. The pipes at the right are conduits for electric wiring.

The inside surfaces of the plates were sandblasted and coated with the high temperature resistant paint before assembling for welding. This was also done for the plates and stiffening channels seen in the view of the half completed structure shown in Fig. 32.

In the final stages of welding, the cross member was reinforced with H beams tying the two large flanges together with supplementary bracing between the beams and the center section. This reinforcement was very effective in holding the shape of the piece while turning it into various positions for welding, and also to prevent spreading and sagging while annealing. By careful fabrication and making allowance for shrinkage, the center line distance of the two large flanges was held to a final tolerance of 1/8 in.

As mentioned previously, the south bearing of the telescope mounting consists of a 7-ft. spherical



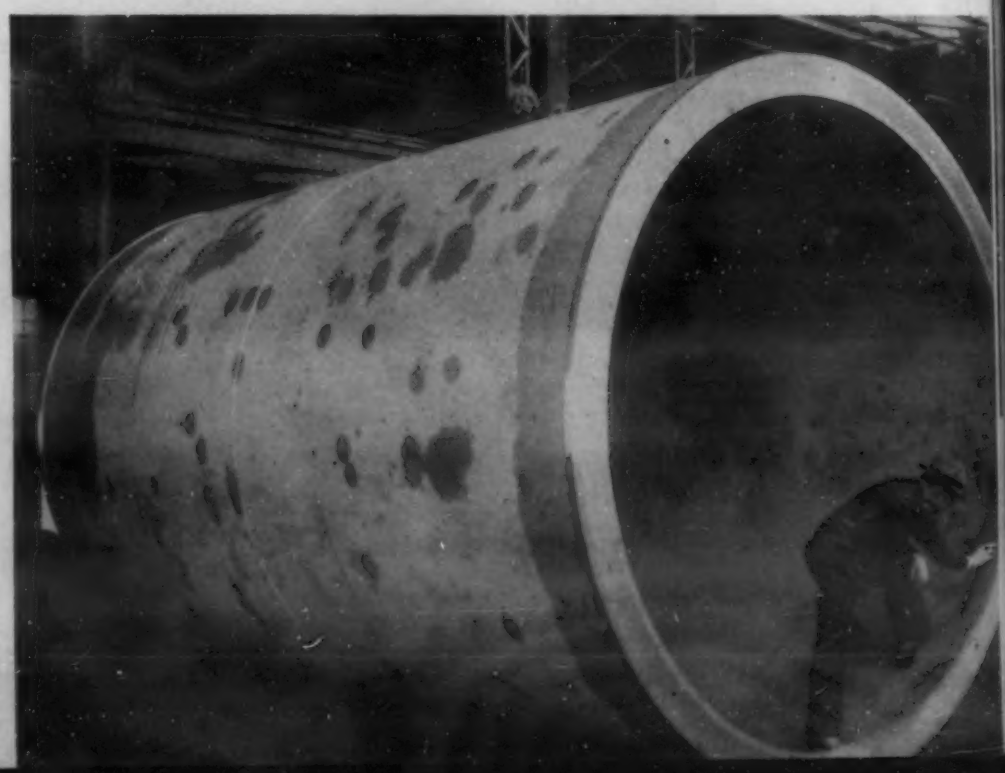


Fig. 26. Original Welding of End Panels to Horseshoe Sections.

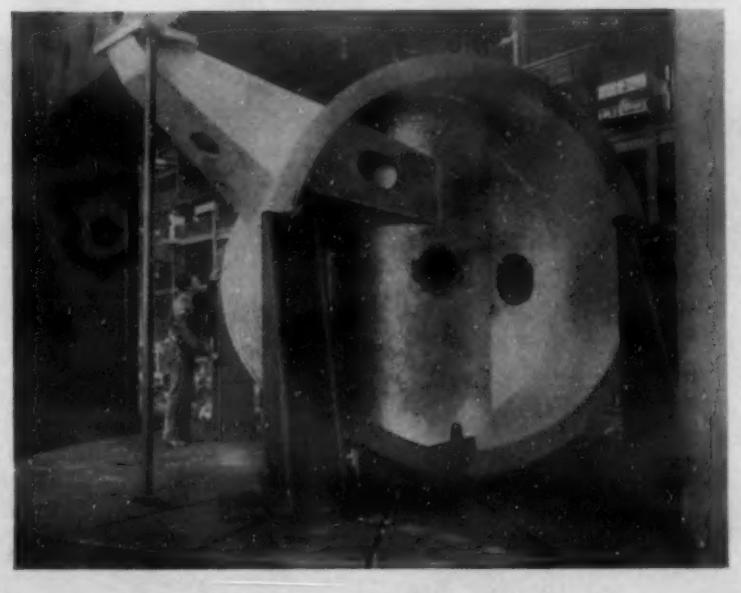

Fig. 29. West Center Yoke Section.

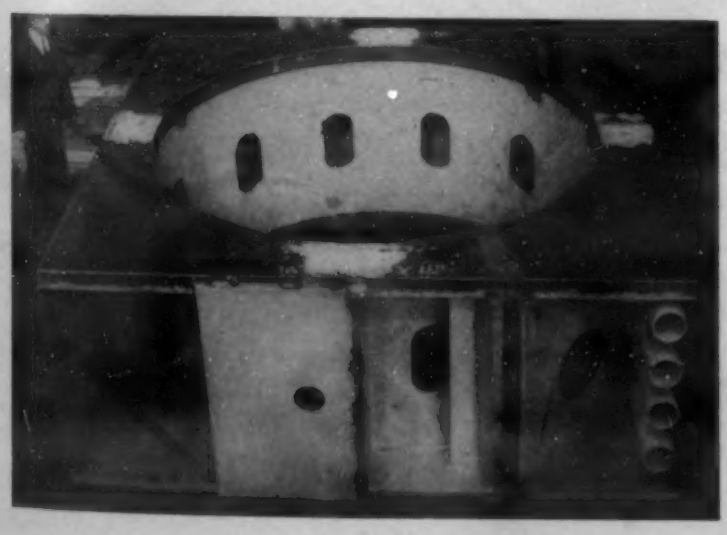
journal bearing carried on three self-aligning shoes. The journal is attached to the north face of the south cross member by means of a large flange, and projects into its central hole. The shoes in turn are carried on brackets projecting from the south bearing box girder.

The hemispherical shell of the journal was required to be well ribbed to obtain a high degree of stiffness. These internal ribs introduced a very serious menace to securing a single piece steel casting of required soundness. It was therefore decided to build up the journal of two separate castings and a large number of ribs welded together. The hemisphere was obtained in the form of a plain shell or bowl casting 4¼ in. thick, made without ribs in order to ensure sound metal. It was first rough machined over the external surfaces. Sixteen ribs of 1½-in. plate were then welded into it. It was next annealed, bored and faced on the ribs, and turned on the edge for a welding groove.

In Fig. 33 is shown the bowl with its welded ribs, ready to be placed on the rough machined flange for welding. This was done with the flange in a horizontal position, with the application of gas burners in the central hole, by two welders working on opposite sides as rapidly as possible. The piece was kept hot up to the time of its transfer to the car of the an-

Fig. 30. South Cross Member.



nealing furnace. The final step was to weld pieces of plate lengthwise on the ribs so as to completely enclose the pockets between them and thus form a very rigid structure, as shown in Fig. 34. Each of these welds was to join two plates with the supporting rib in the shape of a letter T. This was a problem of some difficulty, on account of the extreme likelihood of shrinkage cracks due to the rigidity of the parts. A test was made with three plates of the same thickness, freely supported to form a T, and the shrinkage was found to be sufficient to pull the two lateral plates 12 deg. out of their original position. The problem was then solved in the manner shown at the right of Fig. 34. Each cover plate was milled lengthwise with a slot having a fillet in the bottom and was then slightly bent in a press to the approximate radius of the circle on which they were to lie. The welds were then made without difficulty and without the application of heat, using a hot A.C. arc with a current of 500 amperes.

Fig. 35 shows this final operation. The plate and bracing attached to the small end of the ball was temporary only, and enabled the piece to be rolled on the floor in the manner of a spool for downhand welding. The slots in the plates are clearly seen behind the welder. They were left open since no question of strength was involved. A 1/4-inch vent hole was drilled in each plate to allow the air in the pocket to expand during the final annealing operation, previous to machining. The finished weight of this spherical journal will be 27,000 lbs.

The south bearing shoes mentioned above are carried on hardened support discs or buttons inserted in holes bored in and near the ends of the three brackets shown on the front of the box girder, Fig. 37. These three brackets were torch cut from 16-inch slabs, planed along their three sides, and welded to the box girder. Inasmuch as each of the shoes will carry a load of 160 tons, the weld at the toe of the bracket joining it to the central barrel forging is a very important one. The manner in which the

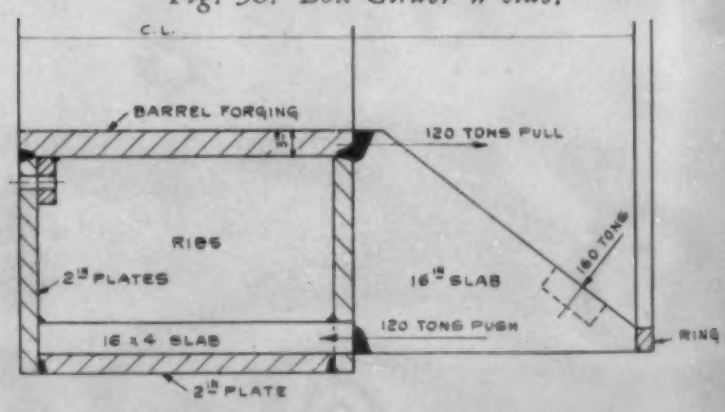
Fig. 37. Box Girder—View from North Side.

various welds were made is shown in Fig. 38. Heat was applied to the brackets while making these heavy welds.

The first stage in the fabrication of the box girder is seen in Fig. 36, the 2-in. plate forming its south side being clamped to the floor. The 1-in. top, bottom, and end plates were machined with the welding grooves seen at the bottom of Fig. 38. The various diaphragm plates were planed on edge to an exact width to ensure a good bearing against the back and front. The whole group of plates was sandblasted and coated with the high temperature paint on their inside surfaces except at the edges where they were to be welded together, as seen in Fig. 37. The box structure was first completed without the bearing brackets and then given a preliminary anneal in order to relieve the stresses in the welds around the ends of the barrel forging. The second and final annealing operation was performed after all brackets, feet, and lugs were welded in place. The box girder as completed weighs 70,000 lbs.

Conclusions



It would have been extremely difficult, if not impossible, to have constructed the mounting for the 200-in. telescope by other means of fabrication than arc welding. The art of welding influenced the basic arrangement, permitting a design that met the general requirements better than any other.

From the manufacturing standpoint, only the two items of trouble referred to above were experienced, and these were quickly overcome, each in a first corrective move. Based on long experience with all methods of fabrication, and also considering the size of the parts under discussion, the record of the welding art as a means of fabrication on this project is excellent. No other fabricating method could have been so free of trouble.

In accuracy of work, several examples have been given to show that uniformity and freedom from distortion can be realized even in large pieces with welded construction.

The 200-in. telescope will stand as a monument to the welding art for many years to come.

Metal Film for Motion Pictures

by WALTER M. MITCHELL

Metallurgical Engineer, Westfield, N. J.

A Reproduction of the Bradey Negative of Abraham Lincoln Made 26 Years Ago on Metal By One of the Carter Processes.

A NEW APPLICATION FOR METALS that has aroused considerable interest in motion picture circles is the use of very light gage metal strip as a base for motion picture film in place of the conventional cellulose. This development is the result of exhaustive research by Dr. Robert W. Carter of the Taylor-Sloane Corp. of New York. The strip used is an aluminum alloy containing about 92 per cent aluminum. While other white metals would be suitable, especially 18 and 8 stainless steel, if they were available in sufficiently light gages and with highly reflective surfaces, so far the aluminum alloy, which has been a special part of the development, is the only metal which meets the requirements.

This strip is used as a base on which the sensitized emulsion is coated—the emulsion and the coating process being a part of the development. Sensitiveness of the film to light is such that the printing time will vary from 1/100 to 1/2 second in standard photographic printing equipment. Development and fixation are carried through after exposure with the ordinary photographic chemicals and present no variation from customary procedure, with the exception that as the metal film is non-absorbent, the time required for these operations is much shortened—an important advantage. Actual tests showed that development, fixation, and drying together with handling and printing of a positive required only 4 min. for the completion of all operations. One important characteristic of the metal film base is the remarkably fine grain obtained, even with the ordinary metol-hydroquinone developer. The chemicals used are apparently without any effect on the metal film itself.

The great advantages of the metal film base are its permanence and the complete elimination of the fire-hazard, since the metal film is absolutely fire-proof. This latter feature should save the motion picture industry thousands of dollars in insurance rates and storage costs; and, it would seem, reduce the cost of installation of projection equipment since the fire-proof booth will no longer be necessary.

Metal film, or rather strip, of the 92 per cent aluminum alloy can be produced 36 in. wide in gages as light as 0.003 in. with proper equipment. Tests have demonstrated that it will withstand repeated bending, as required in passing through the projector, without fatigue or becoming brittle. It is expected that sensitive metal film of this width will be available for slitting into narrower widths when developments are finally completed. Sensitized sheets, and plates, of the aluminum alloy or other metal, will also be available in sizes up to 8 by 10 ft., and in gages up to ¼ in.

Only slight modifications in handling and in projection equipment are required in using the metal film, which can be used for the original negative as well as for the positive for projection purposes. Owing to the white color of the aluminum alloy and the special processing it receives, it has very high reflectivity. Tests by an independent laboratory show a reflectivity factor of nearly 90 per cent against a transmission factor of about 77 per cent for the ordinary exposed and developed cellulose film. Printing and projection of the positive film are necessarily done by reflected light.

Regarding the question of the reproduction of sound for "talking pictures," the sensitized metal

film is admirably adapted for this. Actually an accurate photographic sound track on a smooth fine grained highly reflective surface is a finer medium for sound reproduction than if on cellulose. In the cellulose film the light is scattered in various directions while passing through the cellulose stock, and this may give rise to background noises and blurring of sound. With the metal film the light of the exciting lamp is concentrated on the sound track at 25 deg. incidence. It then passes through two condensing lenses to the photo-electric cell, and the balance of the sound system is standard equipment.

While more details might be given regarding the equipment necessary for exposing the film and projecting the pictures on a screen, enough has been said to demonstrate the usefulness of the metal film base for motion picture work. In regard to costs, it is confidently expected that the price of the metal film will not exceed that of the cellulose film, with the added features of greater strength, permanence, and non-flammability.

To those interested in permanent records the metal film offers decided advantages. Images that are fully permanent can be recorded on both sides of the film, and with the fine grain produced this means that the reproduction of books, documents, and records can be reduced to a very small space. For instance, the Encyclopedia Britannica with its 25,000 pages 8½ x 10½ in., weighing 126 lbs. and occupying a space of 4036 cu. in. can be micro-filmed on metal strip to occupy 30 cu. in. and weigh 6 lbs.

One of the advantages of photography on metals is permanence, and this is highly important when the recording and preservation of documents is concerned. Paper prints, even when made with the greatest care are uncertain at best, even with careful storage, and their inflammability is well known. Photography on metal strips, or sheets, whether of aluminum alloy, 18 and 8, copper, or other metals, offers many advantages and is still in its infancy. It has application for commercial or artistic purposes in advertising, architecture, and the manufacture of novelties. The natural lustre and brilliancy of the prepared metal surface give a life and vitality to the finished picture on metal which is not obtainable with a dead white medium like paper. With the many finishes available on metals and with the colors obtainable, reproductions of great beauty are easily producible, and should find extensive use for science, engineering, advertising, and decorative purposes.

A Few Chuckles

Hot Steam!!

To the Editor: From a booklet published by a large electric company—

"In a tenth of a second steam hot enough to melt ordinary steel is changed, in a turbine like this [pictured], to water too cool to bathe in [! ! !]. The heat energy has been consumed in turning the turbine rotor."

J. M. D.

To Harden Steel

To the Editor: The following item taken from the *Popular Science Magazine* may be of interest to you for a "chuckle":

> F.G., PORTLAND, ORE. An easy method for hardening a piece of steel consists of immersing the metal in a tank of boiling linseed oil to which rosin has been added in the proportion of one-eighth of a pound to a gallon of the oil. When the steel has reached the same temperature as the oil, remove it, dust it over with powdered rosin, and then plunge it into cold kerosene.

G. A. SELLERS,
Acting Head,
Kansas State College,
Manhattan, Kan.

Of course, as applied to steel in general, this is a "chuckle," but there might be compositions in which using boiling oil for isothermal transformation, a sort of austempering, might give usable results.—THE EDITORS.

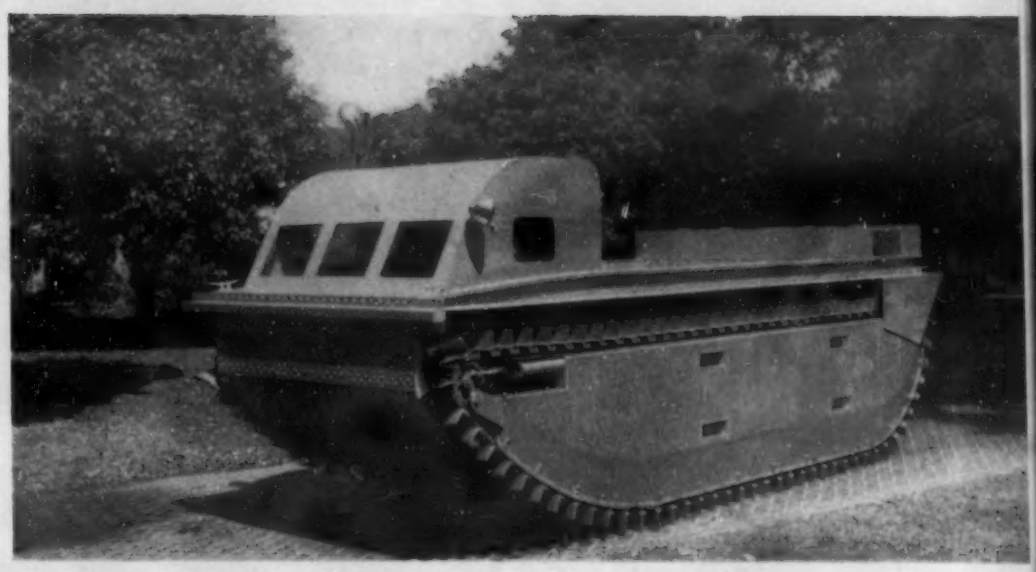
A Chuckle—or a Groan?

In the leading editorial in *Power Plant Engineering* for August we find, in a discussion dealing with corrosion, wear and fatigue of materials in power plant construction, that the words "fatigue" or "endurance" are not used. Instead, the old misphrasing "crystallization" is exclusively employed. This hardy perennial still lives and though we can be philosophical if we find it in *Collier's*, it does gripe us to meet it in a journal whose title includes the word "engineering," and used by the editor at that.—H. W. G.

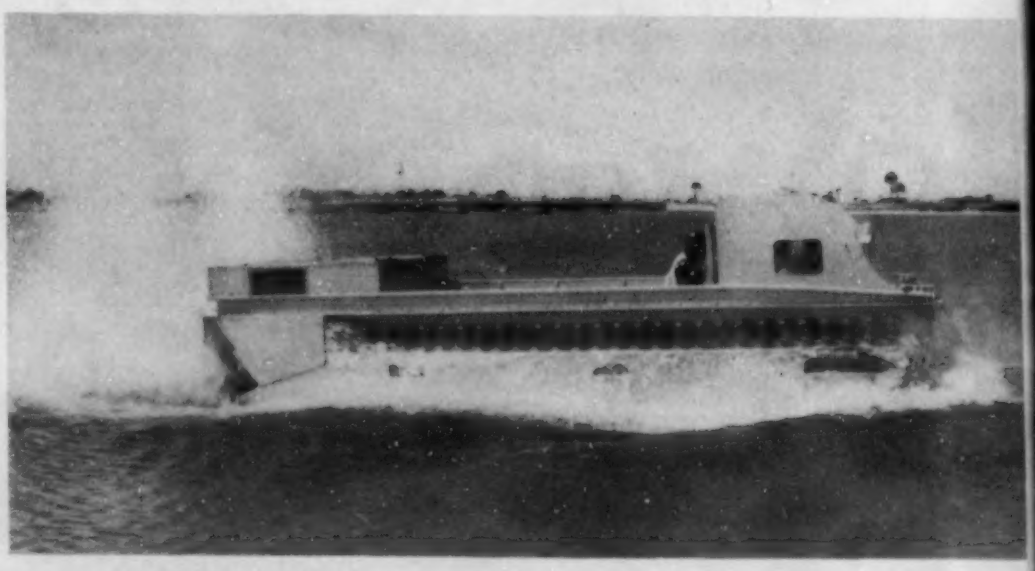
The Beer Can vs. the Bottle

We don't know the most recent statistics of the scrap between the beer bottle and the beer can; moreover the past statistics seem to be too much beset with wishful thinking of the side reporting them, to be quantitatively acceptable.

Qualitative indication that the can may have the upper hand for the moment is found in *Time* for Oct. 9, which, reporting on the American Legion convention in Chicago, concludes its account, "the Legionnaires threw the last empty beer can in the gutter, put away their rattles, and went home."—H.W.G.



Light-Weight "Alligator" of Aluminum Alloy



WHAT SEEMS TO BE a considerable improvement on the "marsh buggy," described in our February 1937 issue, is the new swamp or jungle amphibian conveyance recently designed and built by Donald Roebling of Clearwater, Fla. Constructed almost entirely of aluminum alloy for light-weight, the "Alligator," as its builder has christened it, can travel 15 to 25 miles per hr. on land through tangled growth, and up to 10 miles per hr. in the water. It is non-sinkable, even with its 7,000 lb. cargo compartment full of water, non-capsizable, and, tests show, can even take a 6-ft. dive into deep water without damage to itself or injury to its driver.

The hull, chiefly of riveted construction, is of Alcoa 17ST except for the bottom plate, which is Alcoa 24ST. The propulsion method (on both land and water) is through special Link-Belt roller chains with unusually high T-shaped curved aluminum alloy cleats bolted on. The cleats are of extruded Alcoa 24ST, and have a stem 6 in. high and a top that is 4 in. wide, forged to a 10½ in. radius. Observation of recent operations have shown so little wear of the aluminum treads that no limit to their life can be estimated. The total weight of the "Alligator" is 7700 lbs. without fuel or tools, which add another 800 lbs. The power plant is a Ford V-8 engine with Federal-Mogul high-compression copper cylinder heads, giving about 110 hp. at 3800 r.p.m., and power is delivered to the treads through a standard Ford clutch. All bearings are anti-friction. The gear cases are of cast aluminum for lightness.

Among the other structural features claimed to make the "Alligator" highly adaptable for swamp rescue work are its easy manipulation (it can be turned almost on a dime); its roomy passenger and cargo compartment, which will hold 40 people; and its cruising range, about 400 miles. In addition to this special service for which it was designed, the maker is now suggesting it for exploration and other service in heavy jungle sections. At present, the cost is high and there is as yet little prospect of anything like multiple construction.

Although the "Alligator," described and illustrated here according to data supplied by the builder, is made of aluminum alloy, Mr. Roebling is considering fabricating the next one of stainless steel.

Copper-Zirconium-Cadmium Bronze

by F. R. HENSEL, E. I. LARSEN, AND A. S. DOTY

Metallurgical Consultant, Division Engineer and Metallurgical Engineer, respectively, the P. R. Mallory & Co., Inc., Indianapolis, Ind.

This article presents the results of an extended investigation of alloys of copper, zirconium and cadmium. Its frankness and detail take one behind the scenes in a rather unusual fashion. The details give a lot of information.

The authors present a new high strength, high conductivity alloy or bronze which is claimed to be superior in hardness and strength to the copper-cadmium alloys or bronzes—without severe loss in electrical conductivity. Its present applications include electrical conducting members, welding electrodes and heat-conducting members.—The Editors.

THE SYSTEM COPPER-ZIRCONIUM was investigated by T. E. Allibone and Sykes[1]. It was found that the copper-rich alloys exhibited a variable solid solubility and the limit of solid solubility at room temperatures was placed at approximately 0.2 per cent. A eutectic was formed in the system at approximately 12.5 per cent zirconium. The eutectic temperature was given as 964 deg. C.

Sykes found that with increasing percentages of zirconium, the ultimate strength increased. He reports results as shown in Table I.

Further data on copper-zirconium were reported by J. D. Fast[2]. Data on copper alloys with beryllium and zirconium were reported by Comstock and Bannon[3].

Table I—Effect of Zirconium Content on Strength of Binary Cu-Zr Alloys

Zirconium, Per cent	Brinell Hardness		Ultimate Strength, Tons per sq. in.,	
	As Cast	Normalized	Normalized	Elongation
0	54	60	14	50.0
0.5	60	70	17.3	50.0
1	72	82	18.5	37.5
2	91	91	20.6	25.0
4	101	115	23.8	9.5
6	137	127	27.2	4.0
8	155	137	28.5	1.2

Study of the Binary System Cu-Zr

The authors re-investigated part of the binary system of Cu-Zr and found the location of the eutectic temperature at 966 deg. C. A microscopic analysis showed that even with only 0.3 per cent Zr, a free constituent appears.

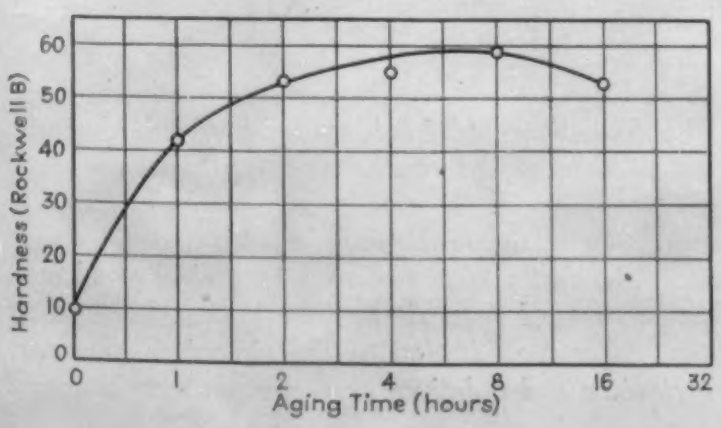
The thermal and microscopic analysis indicated a change of solid solubility with temperature and age-hardening tests confirmed these assumptions. The results of tests made with copper-zirconium alloy (*See also curves in U. S. P. 2097816) containing by analysis 0.93 per cent Zr, are shown in Figs. 1, 2, 3, and 4. In Figs. 1 and 2 the effect of aging time is shown on hardness and electrical conductivity. The materials were quenched from 950 deg. C., which is below the eutectic temperature, and aged at 450 deg. C. The hardness increased from 10 Rockwell "B" after quenching to 59 Rockwell "B," after aging for 8 hrs. The electrical conductivity increased from 49 per cent after quenching, to 76 per cent after aging for 16 hrs. at 450 deg. C. The materials could be cold worked from 50 Rockwell "B" to 75 Rockwell "B," as seen in Fig. 4. This cold work hardness is retained up to fairly high temperatures, as is evident from Fig. 3, in which the hardness is plotted as a function of the annealing temperature.

In comparing the results of the binary copper-zirconium system, with other commercially available materials, it was concluded that the properties, and more particularly the hardness, did not reach values that made the material attractive enough as a substitute for present day alloys. Therefore, in order to obtain a new commercial alloy, of high electrical and tensile properties, the ternary system copper-cadmium-zirconium was investigated in the range

Table II—Effect of Annealing Temperature on the Physical Properties of an Alloy Containing 1% Cd and 99% Cu.

Treatment	Proportional Limit Lbs. per Sq. In.	Yield Point Lbs. per Sq. In.	Tensile Strength Lbs. per Sq. In.	Exten. % in 2 in.	Reduction of Area per cent	Modulus of Elasticity Lbs. per sq. in. × 10^6
Not treated	11,200	61,000	61,200	18.5	64	19.5
1 hr. at 200° C.	19,500	60,500	61,100	17.5	64	19.5
1 hr. at 250° C.	42,000	55,000	60,500	21.9	64	19.5
1 hr. at 300° C.	41,000	49,500	57,500	25.8	65	19.5
1 hr. at 350° C.	6,500	33,000	48,800	33.9	70	21.0
1 hr. at 400° C.	5,850	13,400	38,500	48.6	75	14.2

where such alloys can be hot and cold worked, and treated in such a manner as to develop the best combination of electrical conductivity and tensile properties. The theoretical chemical composition of the final alloy was established as 0.35 per cent Zr, 0.90 per cent Cd, balance Cu. (*U. S. P. 2086329).



The Binary Cu-Cd Alloys

The binary copper-cadmium alloys are known to lend themselves very readily to cold working and the hardness and tensile properties obtained by such cold deformation are retained fairly well up to 300 to 350 deg. C. A series of tests were run on a material containing 1 per cent Cd, balance Cu, and the physical properties determined as a function of the annealing temperature. In Table II the results of these tests are tabulated.

In addition to the above, the effect of annealing temperature on the hardness of a cold worked Cu-Cd alloy (1% Cd) was determined. Fig. 5 shows results of this investigation. From the curve it can be seen that the annealing temperature of this alloy is approximately 350 deg. C.

In the manufacture of high conductivity Cu-Cd alloys, tests have shown that certain impurities, and

particularly iron, will reduce the electrical conductivity. On the other hand, minute percentages of silicon are beneficial. U. S. P. 1908089.

Cu-Zr Concentrate

It was found that the addition of pure zirconium to copper melts was highly impractical from the standpoint of zirconium recovery and formation of zirconium oxide. Zirconium hydride was also used with very little improvement in recoveries and, in addition, the gas evolution prevented production of sound billets.

In order to find a suitable form in which zirconium may be added, a series of tests were conducted on the preparation of suitable Cu-Zr hardener. It was finally decided to use zirconium hydride as the basic material for the preparation of the Cu-Zr alloy. A special technique was developed to produce two grades of hardeners, one containing 12½ per cent Zr, balance Cu, and the other one containing 35 per cent Zr, balance Cu.

These hardeners are prepared by a powder metallurgical process. The sintering is carried out in a reducing atmosphere and the hydrogen liberated by the hydride is an additional protection to prevent oxidation. The process of making this hardener is designated by the trade name "Hydrimet." (Material produced under license arrangement with Metal Hydrides.) The hardener will be attacked slightly by moist air and must be suitably protected in storage.

Melting Procedures for Cu-Zr-Cd Bronze

Zirconium is a material which is highly oxidizable. It therefore acts as a very powerful deoxidizer in copper melts. Tests have shown that by adding 0.1 to 0.2 per cent Zr, copper castings can be produced which are entirely free from oxides or gases. A number of tests were made to determine the zirconium recovery in the Cu-Zr-Cd bronze. Zirconium was added as a 12-½ per cent eutectic Zr-Cu master alloy, and the cadmium was added in the form of compressed briquettes, containing 25 per cent Cd, balance Cu. The copper was melted under a charcoal cover and the melts were deoxidized with a small percentage of copper-phosphorus which was added immediately prior to the addition of the zirconium hardener. The amount of phosphorus was so calculated that no residual amount was left in the melt. The deoxidizer and hardener were added when the temperature of the copper was approximately 2300 deg. F. The melts were then soaked for about 5 min., at which time the cadmium hardener was added. The melts were poured into a chill mold at a temperature of approximately 2100 deg. F., 7 to 10 min., after the addition of the zirconium hardener. Zirconium and cadmium recoveries on three different

Table III—Zirconium & Cadmium Recoveries in Typical Melts of Cu-Cd-Zr Bronze

	Zirconium			Cadmium		
Sample	Added (%)	By Anal. (%)	Recovery (%)	Added (%)	By Anal. (%)	Recovery (%)
L-618	0.67	0.485	72.4	1.2	1.10	91.8
L-619	0.67	0.58	86.5	1.2	1.05	87.5
L-620	0.67	0.485	72.4	1.2	1.00	83.5

melts made in this manner are shown in Table III.

In addition to the above experiments, an investigation was carried out to determine the effect of "soaking time" on the zirconium recovery. The same melting procedure was followed, with the exception that test ingots were cast every 10 min. for 2 hrs., after the addition of the zirconium. Chemical analyses were made on each of the test ingots and the results are given in Fig. 6. From this curve it is quite apparent that the zirconium recovery decreases very rapidly with soaking time. In other words, it is highly advisable to pour the melt as soon as possible after the addition of zirconium in order to obtain good recovery.

Several large production heats were made of copper-zirconium-cadmium bronze. The materials were melted in a 60-cycle Ajax-Wyatt induction furnace. The charge consisted of the following materials:

a. Cathode copper
b. 25 per cent Cd-Cu fused ingot
c. 35 per cent Zr-Cu fused pigs
d. 30 per cent Si-Cu deoxidizers

A typical charge was the following:

	Lbs.
Furnace button	500
Cathode copper	1728
25 per cent Cu-Cd hardener	85
35 per cent Cu-Zr pigs	47

A bottle glass slag cover thinned with borax was used to cover the melt. In general, the procedure used was as follows:

1. Melt down all the copper
2. Deoxidize with Si-Cu
3. Add 25 per cent Cd-Cu pigs
4. Add the 35 per cent Zr-Cu which had been previously wrapped in copper foil.

The glass slag was pushed aside before each of the additions, and in the case of the 35 per cent Zr-Cu hardener, a stirring rod was used to get it under the surface of the bath. No trouble was encountered in the production of any of the melts. The ingots shrank well and showed no signs of swelling or blowing. The fused 25 per cent Cd-Cu hardener went into the melt without excessive boiling or fuming. No trouble was encountered in the addition of the 35 per cent Zr-Cu hardener. It dissolved quite readily. The log of a typical melt is given on the next page:

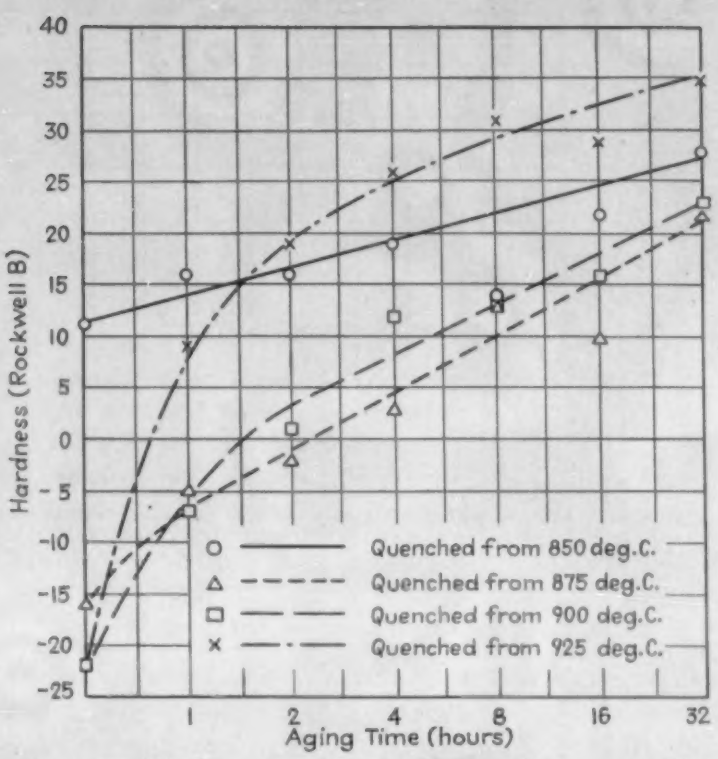

Fig. 8. Hardness vs. aging time after quenching from various temperatures. L854 (98.86% Cu, 0.22% Zr, 0.87% Cd, and 0.08% Si).

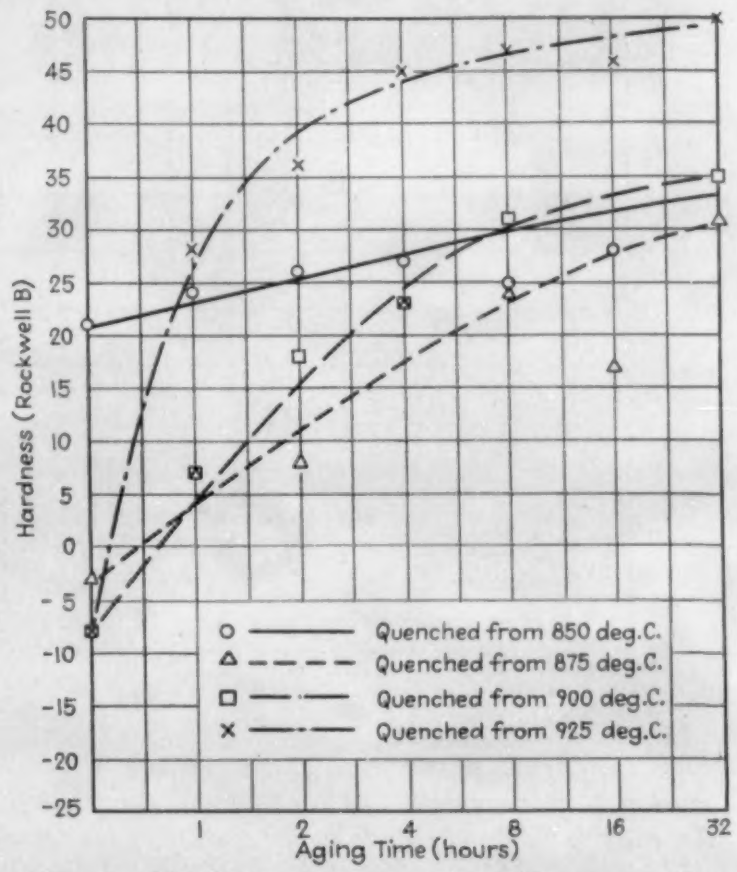

Fig. 9. Hardness vs. aging time after quenching from various temperatures. L855 (98.70% Cu, 0.40% Zr, 0.82% Cd, and 0.09% Si).

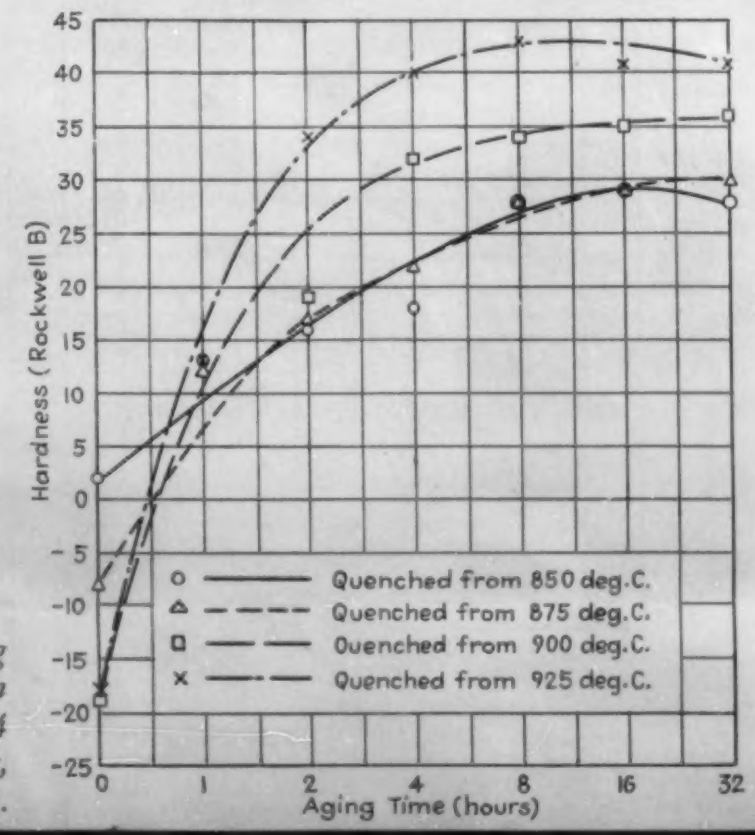

Fig. 10. Hardness vs. aging time after quenching from various temperatures. L864 (98.94% Cu, 0.32% Zr, 0.70% Cd, and 0.03% Li).

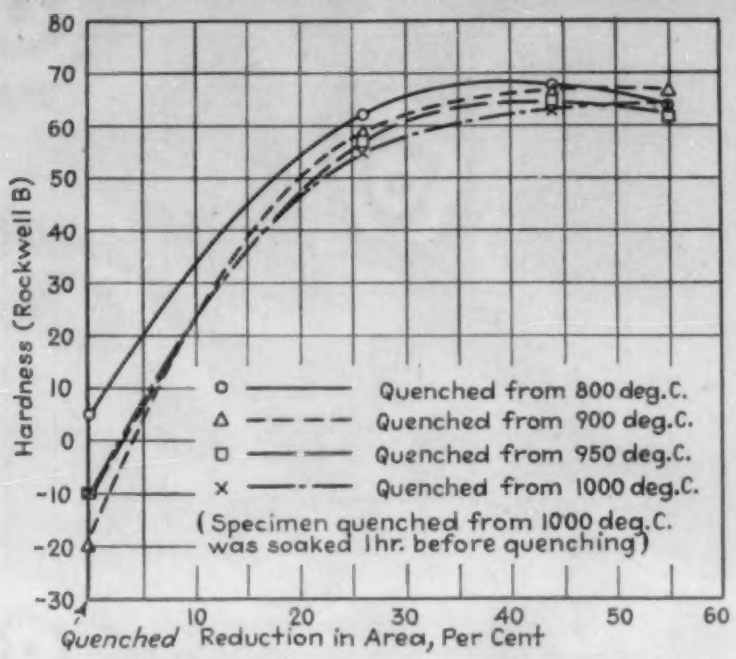

Fig. 11. Effect of quenching temperature on cold working after quenching. L812 (98.97% Cu, 0.28% Zr, 0.72% Cd). Rod, 1/2 in. diameter, quenched and swaged.

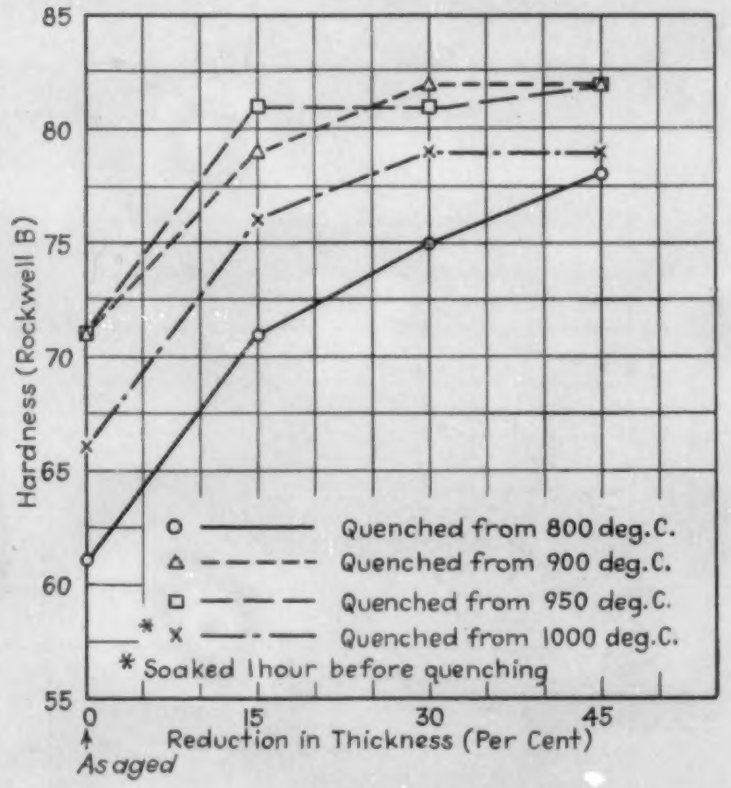

Fig. 12. Effect of quenching temperature on cold working after aging. L812 (98.97% Cu, 0.28% Zr, 0.72% Cd). (1) Rod, 1/2 in. diameter, quenched and swaged cold to 44% R.A. (2) Aged 8 hrs. at 400 deg. C. (3) Sections, 1/2 in. thick, cold hammered to 15%, 30%, 45% reduction in thickness.

Operation	Time
Copper all melted	12:11
Deoxidized with 5 lbs. of 30 per cent Si-Cu	12:11
25 per cent Cu-Cd hardener added	12:14
Temperature 2200 deg. F.	12:17
Started to add 35 per cent Zr-Cu	12:18
All 35 per cent Zr-Cu in melt	12:20
Temperature 2190 deg. F.	12:22
Pouring started	12:22
Pouring finished	12:30

Chips were obtained from the top and bottom of the ingots poured. The analysis of the bottom of the billet would correspond to the composition of the melt at the start of pouring, and the analysis of the top of the billet would correspond to the composition of the bath at the end of the pouring. Table IV lists the compositions of three typical billets.

Table IV—Chemical Analyses of Typical Production Heats of Cu-Zr-Cd Bronze.

	Melt No. 1		Melt No. 2		Melt No. 3	
Element	Bottom	Top	Bottom	Top	Bottom	Top
Copper	98.60	98.69	98.58	98.68	98.55	98.65
Cadmium	0.88	0.80	0.93	0.81	0.93	0.84
Zirconium	0.45	0.47	0.43	0.45	0.43	0.43
Silicon	0.04	0.05	0.04	0.05	0.06	0.04

The results in Table IV indicated the average zirconium recovery to be 63.2 per cent and the average cadmium recovery 95 per cent.

Effect of Deoxidizer on the Age Hardening Characteristics

A series of tests were conducted in which phosphorus, silicon, magnesium and lithium were used as deoxidizers.

1. It was definitely established that the presence of phosphorus seriously interferes with the age hardening of the alloy. An alloy was prepared having the following analysis:

Copper	98.70 per cent
Zirconium	0.47 per cent
Cadmium	0.72 per cent
Phosphorus	0.05 per cent

This alloy did not respond to heat treatment. In order to verify the result, two more billets of the same intended composition were made and found to confirm the previous results.

2. An alloy was made of the following composition:

Copper	98.66 per cent
Zirconium	0.43 per cent
Cadmium	0.83 per cent
Magnesium	0.06 per cent

The age hardening results of this alloy are shown in Fig. 7. The most pronounced hardening resulted by quenching from 900 deg. C. and aging for ap-

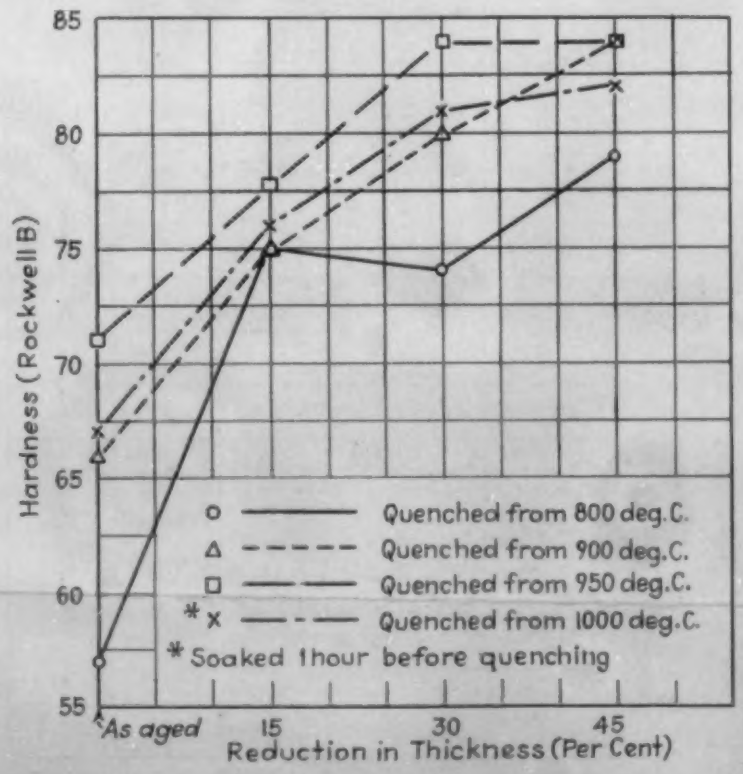

Fig. 13. Effect of quenching temperature on cold working after aging. L812 (98.97% Cu, 0.28 Zr, 0.72% Cd). (1) Rod, 1/2 in. diameter, quenched and swaged cold to 55% R.A. (2) Aged 8 hrs. at 400 deg. C. (3) Sections, 1/2 in. thick, cold hammered to 15%, 30%, 45% reduction in thickness.

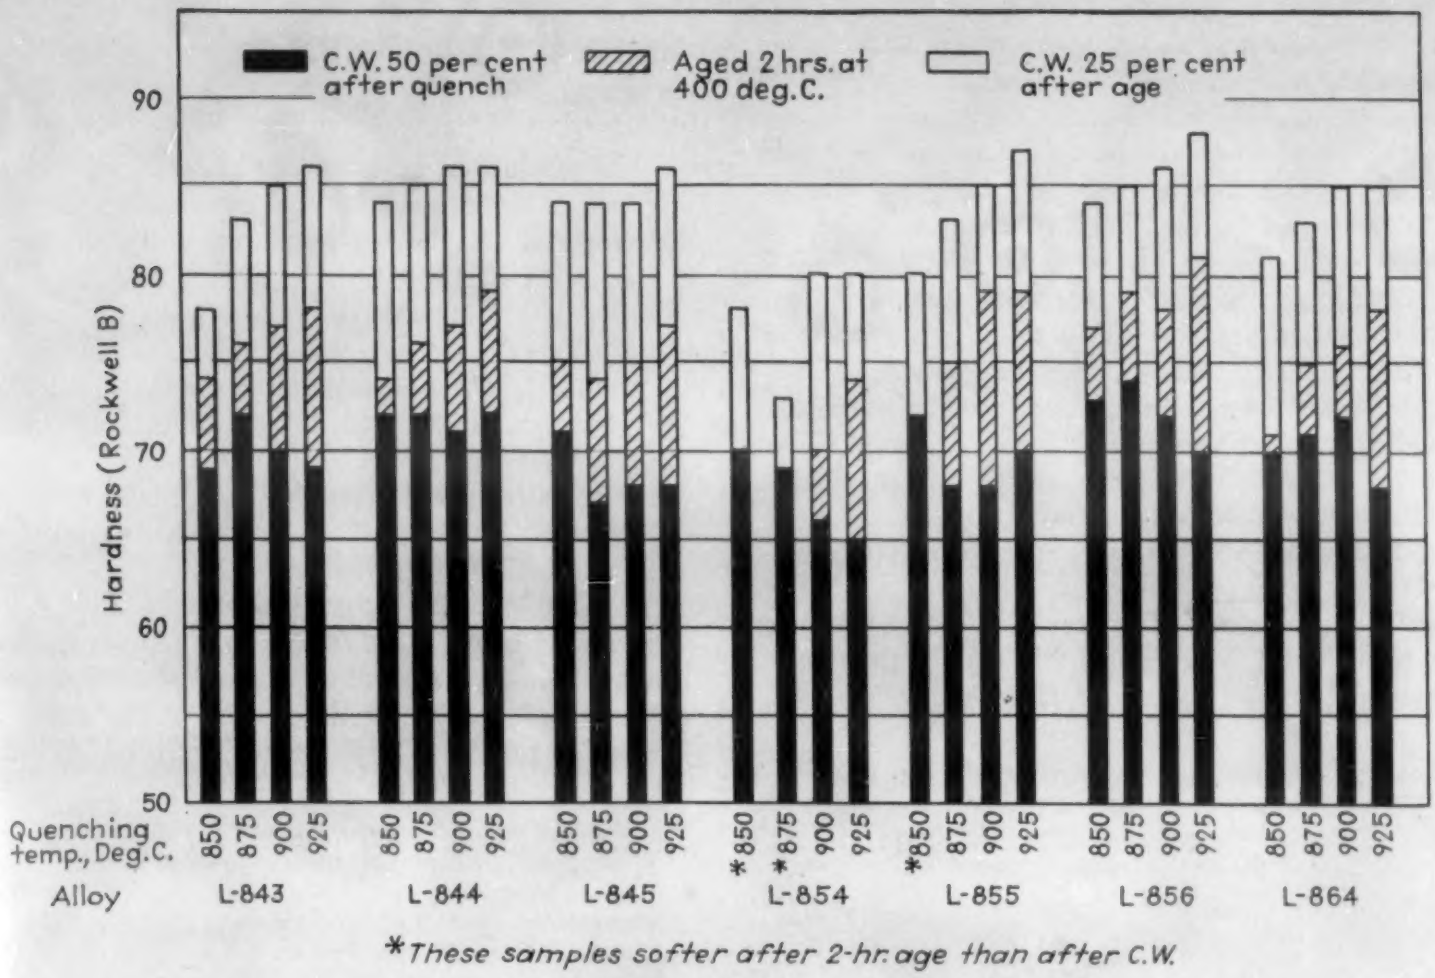

Fig. 14. Diagram showing hardness at various points in process of manufacture. L843, L844, L845, L854, L855, L856, L864. Samples were: (1) Quenched. (2) Cold pressed 50 per cent reduction in thickness. (3) Aged 2 hrs. at 400 deg. C. (4) Cold pressed 25 per cent reduction in thickness.

proximately 8 to 16 hrs. at 450 deg. C.

3. An alloy was made of the following composition:

Copper	98.86 per cent
Zirconium	0.22 per cent
Cadmium	0.87 per cent
Silicon	0.08 per cent

The age hardening curves of this alloy are shown in Fig. 8. In this case, the optimum quenching temperature was 925 deg. C., producing the most pronounced aging results at 450 deg. C.

4. Since the billet reported under "3" had a low zirconium content, a duplicate sample was made aiming at a higher zirconium percentage. This alloy had the following composition:

Copper	98.70 per cent
Zirconium	0.40 per cent
Cadmium	0.82 per cent
Silicon	0.09 per cent

The age-hardening results are shown in Fig. 9. It is quite evident that the average hardness values are considerably above those obtained in the billet mentioned under "3", containing only 0.22 per cent Zr.

5. A billet was made containing 98.94 Cu, 0.32 Zr, 0.70 Cd, and 0.03 per cent Li. The results of the heat-treating tests are shown in Fig. 10. The material ages properly. The best quenching temperature is 925 deg. C.

Effect of Combining Cold Working and Aging

A series of cold working tests were made on a material of the following composition (Alloy L-812):

Copper	98.97 per cent
Zirconium	0.28 per cent
Cadmium	0.72 per cent

A material of this type was quenched from various temperatures and then cold worked various percentages. The results of these experiments are contained in Fig. 11. From this curve it is evident that about 45 per cent cold work will give the maximum increase in hardness. It was, therefore, decided to use approximately 40 to 50 per cent cold work after quenching for processing commercial quantities of the Cu-Zr-Cd bronze.

In order to further increase the hardness, a cold working operation was used after the aging treatment. Tests were made on the same material as above, and the results are contained in Figs. 12 and

13. It is evident that 25 to 35 per cent reduction after aging will considerably raise the hardness. It was, therefore, decided to use in the commercial procedure a 25 to 35 per cent cold reduction. The actual hardness values shown in the previous two illustrations are somewhat low, due to the fact that the zirconium content is slightly below the specified limit.

It should also be noticed that aging was carried out in these experiments at 400 deg. C., rather than at 450 deg. C. The cold working after quenching rapidly increases the rate of aging and therefore it was found safe to reduce the aging temperature to 400 deg. C. In Table VI and Fig. 14 the results are given on hardness of a series of alloys which were quenched from 850, 875, 900, and 925 deg. C., cold worked 45 to 50 per cent aged 1 and 2 hrs., at 400 deg. C., and further cold worked to 25 to 50 per cent reduction in thickness. Table V gives the chemical composition of this series of alloys.

Table V—Chemical Composition of the Series

Alloy No.	Cu	Zr	Cd	Si	Li	Mg
843	98.68	0.41	0.88	...	...	...
844	98.52	0.48	0.98	...	...	...
845	98.66	0.43	0.83	...	...	0.06
854	98.86	0.22	0.87	0.08	...	...
855	98.70	0.40	0.82	0.09	...	...
856	98.53	0.59	0.81	0.04	...	...
864	98.94	0.34	0.70	...	0.03	...

From these data it is quite evident that, with the proper treatment, the new alloys can be produced with a minimum hardness of 80 Rockwell B and an average hardness of 83 to 85 Rockwell B, in sections up to 1 in. diameter.

General Physical Properties of Production Heats in Cu-Zr-Cd Bronze

The production heats on this material were investigated as far as hardness and conductivity are concerned, and also tensile tests were made on round rods drawn to various dimensions. The values in Table VII are average values taken from inspection reports.

The material can also be forged satisfactorily. It was found that extruded billets would forge more readily than cast billets. A large number of seam welding wheels were made by forging, and the average hardness results obtained on such discs are shown in Table VIII.

It is quite evident that without any difficulties, hardness values of 78 to 83 can be obtained. A stress strain curve was prepared on a sample that was taken from a $\frac{5}{8}$-in. diameter drawn rod. The curve is shown in Fig. 15. The properties which we obtained were the following:

Ultimate strength, Lbs. per sq. in.	78,000
Yield point (0.2 per cent in permanent set) Lbs. per sq. in.	73,000
Proportional limit, Lbs. per sq. in.	37,500
Elongation in 2 in., per cent	11
Reduction in area, per cent	40
Hardness (Rockwell B)	84-86
Electrical conductivity I. A. C. S., per cent	78

The softening characteristics of the alloy were determined by annealing the material 2 hrs., at various temperatures. The results of this test were shown in Fig. 16. As can be seen, the drop in hardness does not start until about 450 deg. C. The softening, of course, will be a function of the amount of cold working that has been applied to the material and with a very high amount of cold working, the ma-

Table VII—Average Hardness Values of Various Diameter Rods of Cu-Zr-Cd Bronze

Diameter, Ins.	Rockwell B Hardness	Conductivity, Per cent
$\frac{7}{16}$	81—87	78—81
$\frac{1}{2}$	81—85	80—82
$\frac{5}{8}$	80—84	77—81
$\frac{3}{4}$	82—85	76.5—78
$\frac{7}{8}$	85—86	75—77
1	87—88	77—78
$1\frac{1}{8}$	81—83	83—86
$1\frac{1}{4}$	81—82	85—87
$1\frac{1}{2}$	80	78.3

Table VIII—Average Hardness Values on Various Sizes of Forged Rings and Discs of Cu-Zr-Cd Bronze

Size of Discs or Rings, In.	Hardness (Rockwell B)
10 dia. x $\frac{3}{4}$ thick	78—81
$10\frac{1}{2}$ dia. x $\frac{1}{2}$ thick	80—82
10 O. D. x 3 I. D. x $\frac{3}{4}$ thick	78—81
$8\frac{1}{2}$ dia. x $\frac{1}{2}$ thick	82—85
11 dia. x $1\frac{1}{8}$ thick	79—81
12 dia. x $\frac{5}{8}$ thick	79—83

terial will over-age rather quickly and softening might occur at temperatures as low as 400 deg. C.

Hardness tests were also conducted at temperature. The following values were obtained for the Cu-Zr-Cd bronze:

Temperature	Hardness, Brinell
Room Temperature, Deg. C.	148
125	140
175	132
230	123
300	120
350	119

Hardness readings at elevated temperatures were taken, using an apparatus somewhat as follows:

The specimen to be tested in the form of a small rectangle, approximately ½ in. sq. and ¼ in. thick, was placed on a platen inside a small furnace in which the temperature could be accurately controlled. The standard 10 m. m. Brinell ball and mounting fixture were also enclosed in the furnace. The assembly was heated to the predetermined temperature and allowed to soak a sufficiently long time to insure uniform temperature distribution within the specimen. The load was then applied and held for 30 sec. at temperature. The specimen was then removed and the impression measured with the usual Brinell microscope.

Effect of Quenching Temperature on the Microstructure

It was found that materials that had been quenched from too high a temperature after hot forging, would crack on subsequent cold working. A microscopical investigation was made which showed the following results:

1. After quenching from 800 deg. C., some grain growth takes place. The resulting material had an average of 5000 to 7500 grains per square m. m.
2. After quenching from 900 deg. C., considerable grain growth occurred, the number of grains being 50 to 100 per square m. m.
3. After quenching from 950 deg. C., the grain size was similar to that of the previous experiment, but a segregation in the grain boundaries was noticeable.
4. After quenching from 1000 deg. C., the segregation in the grain boundaries was very pronounced, the grain size still remaining the same as after quenching from 900 deg. C.
5. After holding for 1 hr. at 900 deg. C., and quenching, the grain boundary segregation was similar to that found in the pieces quenched from 950 deg. C.
6. After holding for 1 hr. at 1000 deg. C., and quenching, the segregation in the grain boundaries was extremely bad, the grain size being approximately 50 grains per square m.m. This investigation indicated that the quenching temperature should not exceed 950 deg. C., and should preferably be 900 deg. C., and that the material should not be held for too long a period of time at such a high temperature.

Effect of Zirconium on Other Than Cadmium Bronzes

In connection with the investigation of Cu-Zr-Cd

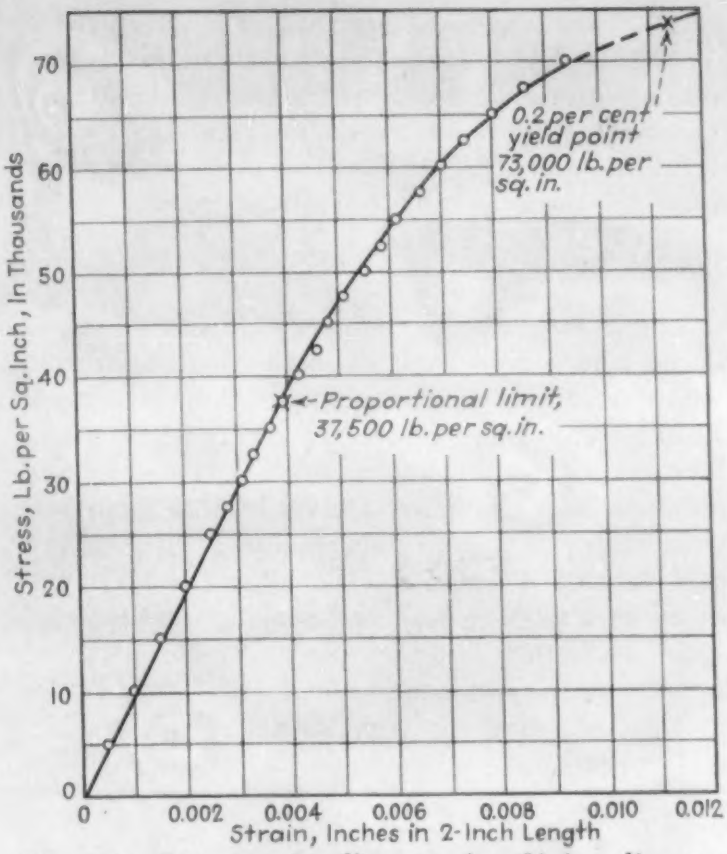

Fig. 15. Stress-strain diagram for ⅝-in. diameter drawn rod of copper-zirconium-cadmium bronze.

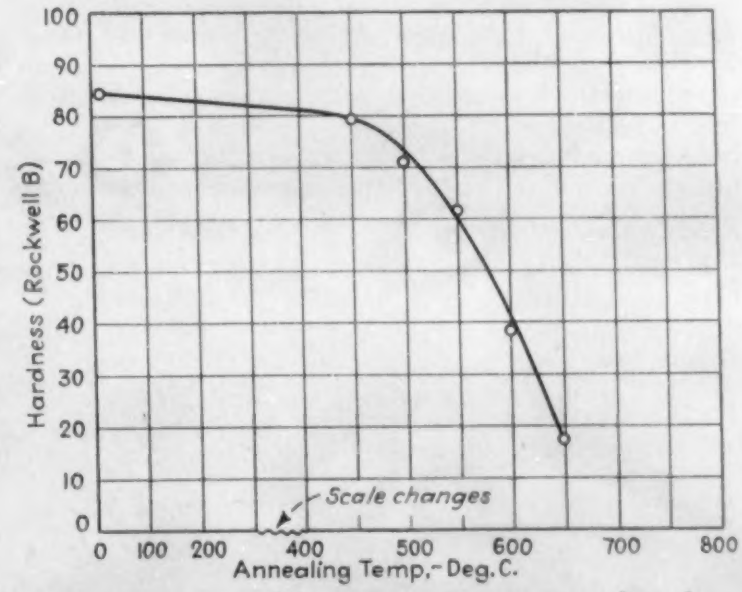

Fig. 16. Annealing curve on copper-zirconium-cadmium bronze.

alloys, also a number of other systems were studied, such as the Cu-Zr-Sn alloys. It was found that in this system, zirconium also causes age hardening. The actual curves obtained in this system are contained in U. S. Patent 2,136,918.

Another system that was studied and found to give excellent properties, was the Cu-Zr-Fe alloys. Materials of this type could be age hardened without cold working, to a Rockwell B hardness of 62 to 65 and an electrical conductivity of 55 to 60 per cent. Further cold working raised the Rockwell B hardness

to 85. The alloys are described in U. S. Patent 2,137,881. It was also found that the addition of zirconium greatly improves the alloys hardened with chromium silicides and nickel silicides (U. S. Patent 2,136,211 and 2,137,282). This investigation, however, will form the subject of another paper.

Conclusions

The investigation of the Cu-Zr-Cd alloys has produced a new high strength, high conductivity alloy which constitutes a very substantial improvement in hardness and strength over present straight Cu-Cd bronzes, without causing a severe loss in electrical conductivity. The alloys can be manufactured very satisfactorily on a large scale and can be handled in a mill without difficulties. The alloy has been produced on a tonnage basis and is being used for electrical conducting members, welding electrodes and heat-conducting members. The material should form an excellent alloy for high strength, high conductivity wire, such as is used for overhead wire and trolley wire.

Acknowledgment

The authors wish to acknowledge the very helpful assistance of Harry Croft, chief metallurgist of the Cleveland Works of the Chase Brass & Copper Co., where the new metal has been produced for the P. R. Mallory & Co., Inc. The authors, also, wish to thank the management of the P. R. Mallory & Co., Inc., for permission to publish these data. Acknowledgment is also given the valuable assistance of Dr. P. P. Alexander, general manager of Metal Hydrides, Inc.

A Study in Export Data of Stainless and Alloy Steels

An analytical study of official export and import data often brings to light some interesting trends and facts. It is only since the beginning of 1937 that Government export statistics have revealed the export movement in stainless and alloy steels. The following study of these data has been made which is interesting as showing a decided foreign demand for certain American alloy products.

Rolled Stainless Steels

In the stainless steels, of particular interest are the exports of bars, plates, sheets and strip. The following table shows the export data for 1937, 1938 and to Oct. 1, 1939, in gross tons:

EXPORTS OF STAINLESS STEELS

	Bars	Plates	Sheets	Strip	Totals
1939 (9 mos.)	235	93	665	722	1715
1938	669	277	1681	632	3259
1937	223	148	1440	644	2455
1936	....	....	....	....	....
Totals	1127	518	3786	1998	7429

Thus in the 2 yrs. and 9 mos. foreign consumers have taken over 7400 gross tons of stainless bars, plates, sheets and strip in which sheets have predominated. The monthly outgo has varied from about 270 tons per month in 1937 to 198 tons monthly in 1939.

Rolled Alloy Steels

More impressive has been the movement abroad of American rolled alloy steel products, exclusive of stainless steel. The following table gives these data in gross tons:

EXPORTS OF ROLLED ALLOY STEEL (EXCLUSIVE OF STAINLESS)

	Bars	Plates	Sheets	Strip	Totals
1939 (9 mos.)	9142	1866	2593	401	14002
1938	7932	3034	3364	450	14780
1937	6398	5054	4730	1140	17322
1936	....	....	....	....	.....
Totals	23472	9454	10687	1991	46104

Thus in the 2 yrs. and 9 mos. since 1936 about 44,700 gross tons of rolled alloy steels (exclusive of stainless) have been sent abroad—a fairly sizable tonnage.

Ingots, Castings and Forgings

Besides these rolled alloy products—stainless and alloy—there has been an appreciable demand for alloy and stainless ingots, billets and blooms, and also castings and forgings. In this case the Government data do not separate the alloy and the stainless. The data for these are as follows in gross tons:

EXPORTS OF ALLOY AND STAINLESS INGOTS, CASTINGS AND FORGINGS IN GROSS TONS

	Ingots, etc.	Castings	Forgings
1939 (9 mos.)	14762	1114	1432
1938	7736	1146	993
1937	7232	1647	933
1936	....	....	....
Totals	29730	3907	3358

Thus in the 33 months' data under review the exports of ingots, billets and blooms, castings, and forgings have totaled over 28,800 tons with ingots, etc. comprising over 75 per cent of the total.

Summary

Recapitulating—the total exports of these stainless and alloy products have been as follows for the 33 months in gross tons:

Bars	24599
Plates	10472
Sheets	14473
Strip	3989
Ingots, etc.	29730
Castings	3907
Forgings	3358
Total	90528

This export movement from Jan. 1, 1937, to Oct. 1, 1939, or 33 months, has reached a total of over 80,750 gross tons. Of this, rolled alloy and stainless steel has comprised over 64 per cent with ingots, etc., about 27 per cent. This is a really commendable showing. With no data for 1936 or earlier, further comparisons are not possible. It is safe, however, to assume that the movement has reached its largest proportions in the last 2 or 3 yrs. The European war will interrupt this trend but when normal export shipments are resumed, it is probable that foreign demand for these stainless and alloy rolled, cast and forged products will further expand.—E.F.C.

Fatigue Problems in Structural Designs

PART 2 • CONCLUDED FROM NOVEMBER

BY A. V. KARPOV

Consulting Engineer, Grant Bldg., Pittsburgh

IV. FATIGUE DIAGRAMS OF STRUCTURAL ALLOYS

THE preparation of complete stress-resisting capacity diagrams requires a considerable number of long drawn tests, and in many cases complete diagrams are not available. Nevertheless, it would seem that the designer, before accepting an alloy, should request the furnishing of as complete diagrams as possible.

The tests which are necessary to obtain data for such diagrams are standard fatigue tests that can be conducted in nearly every fatigue testing laboratory.

The number of load applications to be considered depends entirely on the rapidity of probable stress variations and on the proposed life span of the structure. It may be entirely reasonable not to go to an unlimited number of load applications for many structures.

For structural elements the time-stress regime of which is similar to that given in Fig. 2, it may be possible to consider the pulsating strength only. For time-stress regimes similar to the ones shown in Fig. 3, the whole diagram including the pulsating and fatigue strength must be considered.

Fig. 7 shows, for instance, a complete bending, tension shear fatigue diagram (unlimited number of load applications) for polished specimens of silicon steel. The characteristics of this alloy are: C 0.25, Si 0.20 and Mn 0.60 per cent with ultimate strength in tension, 64,000 lbs. per sq. in. and elongation 20 per cent in 4 in.

The reduction of fatigue strength due to surface conditions may be established for steel alloys with relation to the ultimate strength as shown in Fig. 8. This reduction diagram is only approximate and variations are possible for different kinds of steel. Nevertheless it shows clearly the increased sensitivity of higher strength alloys.

In application of such diagrams to practical design problems, the region of permissible stress variations should be established as shown in Fig. 9. Using the fatigue diagram determined from tests made on polished specimens, reductions must be applied:

1. Due to the increased stress-resisting capacity of small sized specimens as compared with the larger sized structural elements.
2. Due to the surface conditions of the structural element which as a general rule will not be polished.
3. Safety factor reduction.

The remaining part of the diagram will then represent the safe region within which variable stresses can be applied without danger.

Such a diagram can be applied directly only to parts of structural elements that are continuous and at such points where no stress concentrations are possible.

The furnishing of such diagram may be considered as the final step defining the border line between the material testing and the structural laboratories. The structural engineer can hardly take a part in the investigation of alloys and in the long drawn tests that are necessary to produce such diagrams. A proper appraisal of structural alloys however is possible only if complete fatigue tests diagrams are available. In developing, for instance, high strength steel alloys, the structural designer is vitally interested in obtaining alloys that are structurally properly balanced. It is of little value to obtain an alloy of high ultimate strength without a corresponding increase of the yield point and the fatigue strength, or with an ex-

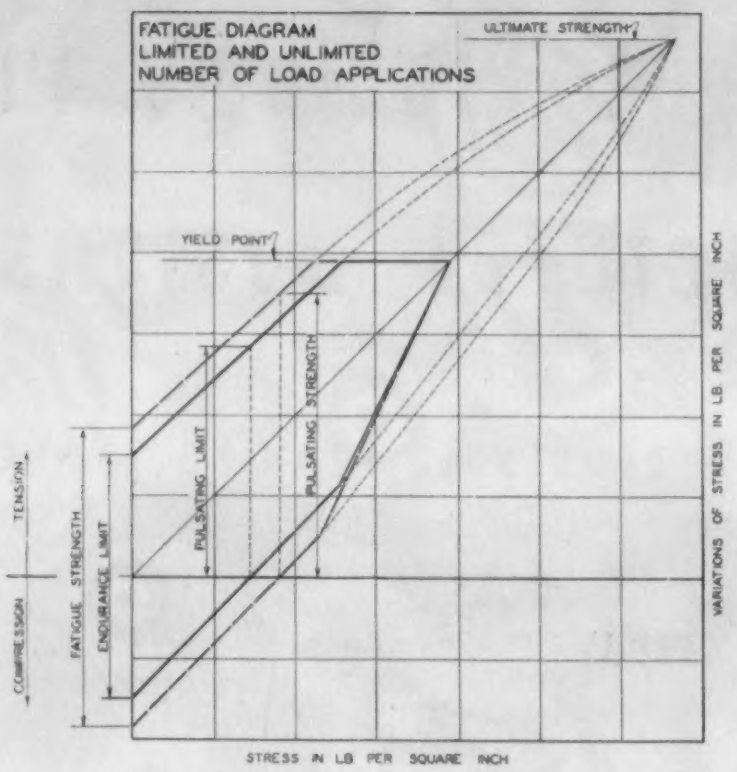

Fig. 6. Fatigue diagram—limited and unlimited number of load applications.

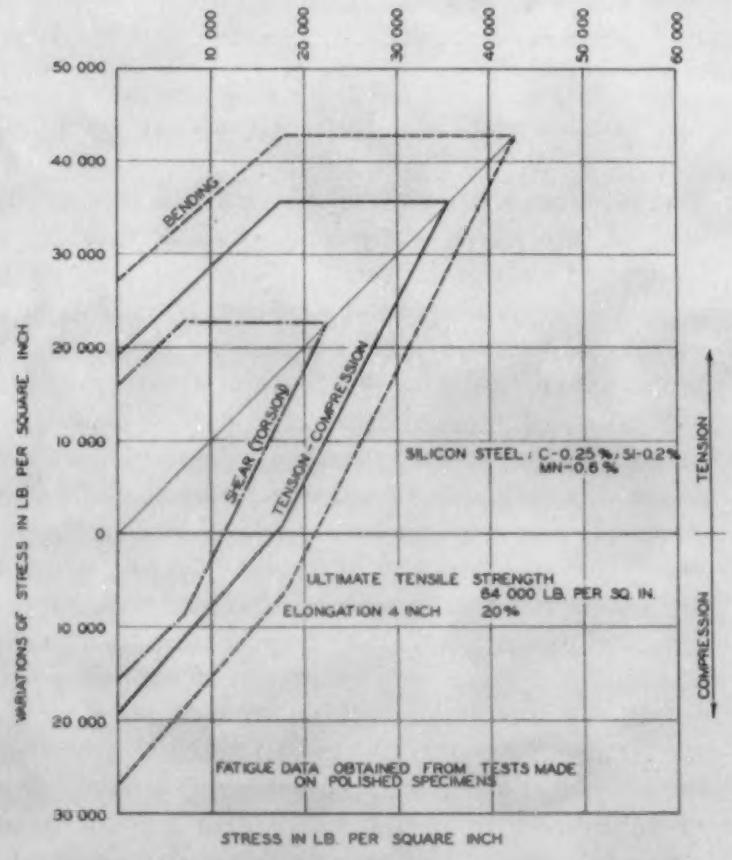

Fig. 7. Fatigue diagram—bending, tension, shear.

cessive lowering of elongation and ductility.

On the other hand the stress concentrations depend only to a small extent on the structure of the alloy, being predominantly and distinctly design problems. Since the stress concentrations have such an important bearing on the fatigue properties, the structural designer must continue the work of the material tester and by theoretical investigations and structural laboratory tests determine the fatigue properties of structural elements fabricated from alloys the fatigue properties of which are determined by the material tester.

V. FATIGUE PROPERTIES OF STRUCTURAL ELEMENTS

In determination of fatigue properties of materials, specimens can be used in which no appreciable stress concentrations occur or tests can be so run that the influence of stress concentrations is definitely limited to more or less known conditions. In engineering designs such means cannot be satisfactorily employed.

The major problem in applying the fatigue data to actual designs would be therefore the determination of the actual stress at the danger points. This problem in some instances may be rather complicated even in a continuous structural element, and it becomes still more complicated if consideration is given to the joints and points at which the forces are applied.

Stress Concentrations

In dealing with stresses that are developed by static loads it is customary to consider primarily, and very often exclusively, the stress in one plane or one cross-section only, disregarding the fact that there must be a difference in conditions at the boundaries as compared with the conditions within the structural member.

After forces are applied to a structural member stresses are developed at each point of it and as a general rule in three directions. The visualization of the stress conditions may be obtained by the use of stress fields or stress lines analogous to the fields and lines used in the study of electrical phenomena. If such analogy is accepted, the expression of the flow of stress may be employed.

If stress in one direction only is considered, then it can be represented by a single stress field; if stress in two or three directions is considered, then two or three stress fields must be drawn. The general representation of a three-dimensional stress field may be obtained by drawing of the three stress fields of the principal stresses.

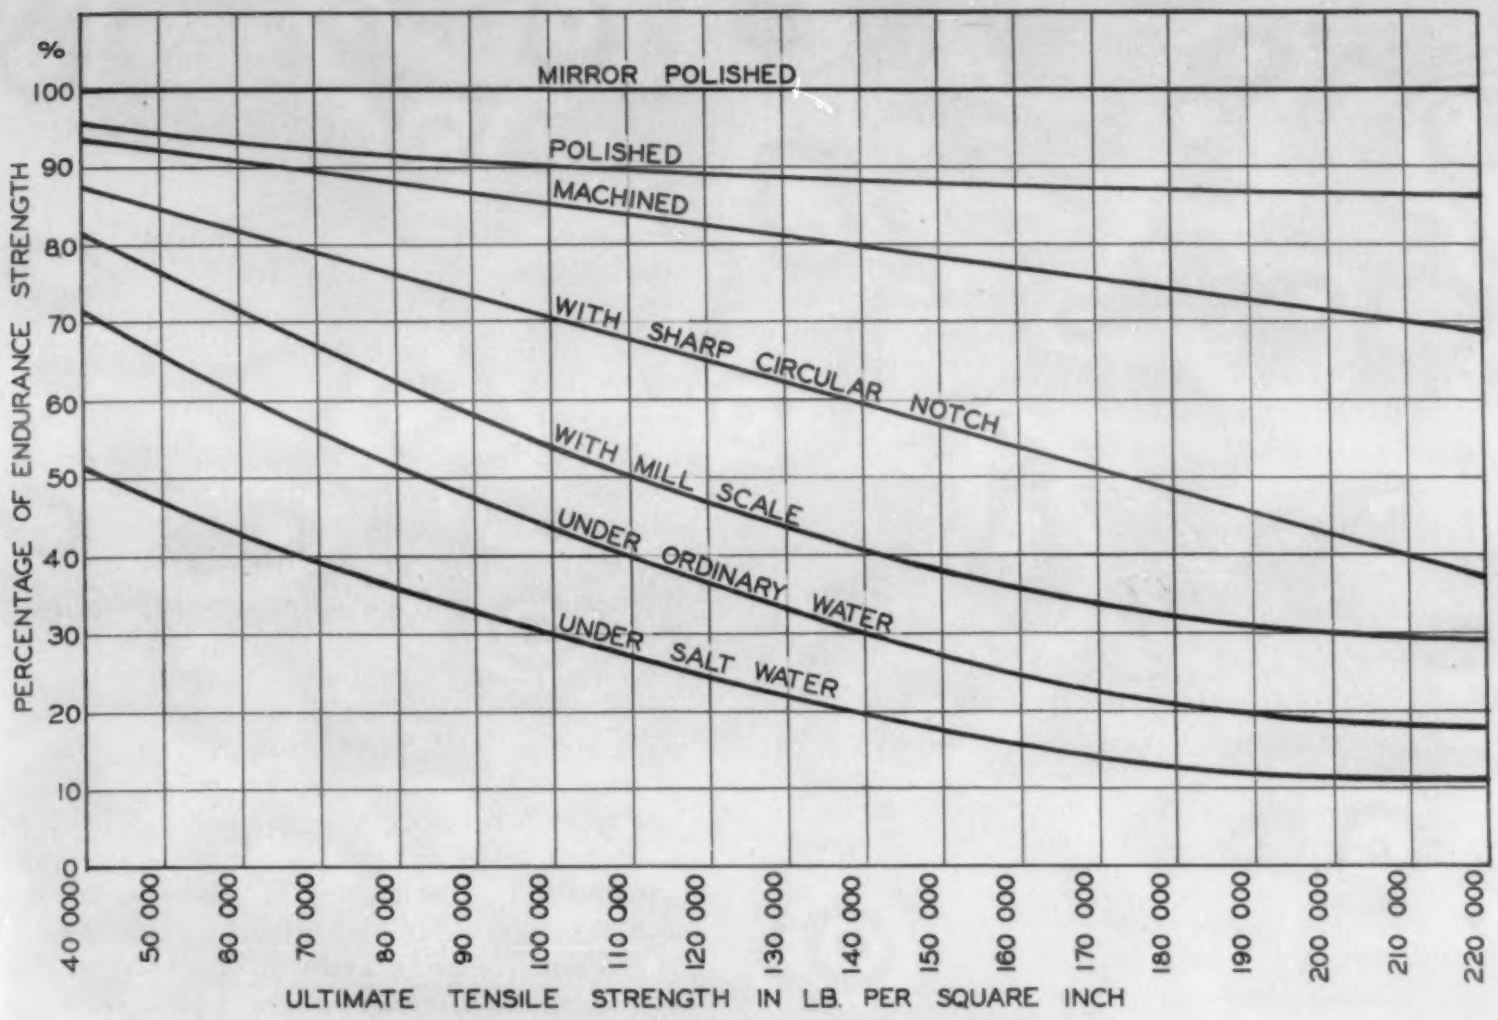

Fig. 8. Fatigue strength reduction due to surface conditions.

Flow of Stress

The purpose of every engineering structure is to receive external and gravitational forces and to distribute, transform and transmit them to some outside medium. Such action requires a continuous flow of stress within the structural elements and the transmitting of forces from one element to the other.

The flow of stress in many respects is very analogous to the flow of liquid. As long as no changes in conditions occur, the flow is more or less uniform and no stress concentrations occur. Any change in conditions disturbing the uniform and smooth flow results in stress concentrations which will tend gradually to smooth out if at a sufficient distance from the disturbance the uniform flow conditions are again re-established. More abrupt changes in the flow conditions are responsible for higher stress concentrations and, vice versa, a gradual and smooth change in flow conditions will result in moderate stress concentrations. The boundary will influence the stress conditions in the same way as the friction at the boundaries will influence the conditions of the boundary layer of a flowing liquid. A uniformity of the stress flow may be preserved in a uniform structural member, but at places where external forces are applied, or where changes in cross-section take place, or where the member joins other members, a flow disturbance must result. Even continuous welding will cause disturbances of the stress flow due to the unavoidable differences in the physical properties of the base metal and the welded joint.

The theoretically perfect method of determining fatigue properties of structural elements would be to determine the values of stress concentrations and to correlate these values with the data obtained from fatigue tests of materials. Such procedure however is very difficult due to limited knowledge of stress concentration factors, absence of satisfactory methods of theoretical determinations of such factors, uncertainty of exact measurements of stress in the small areas at which local stress concentrations occur.

In the present state of engineering knowledge, a reliable answer can only be obtained by the running

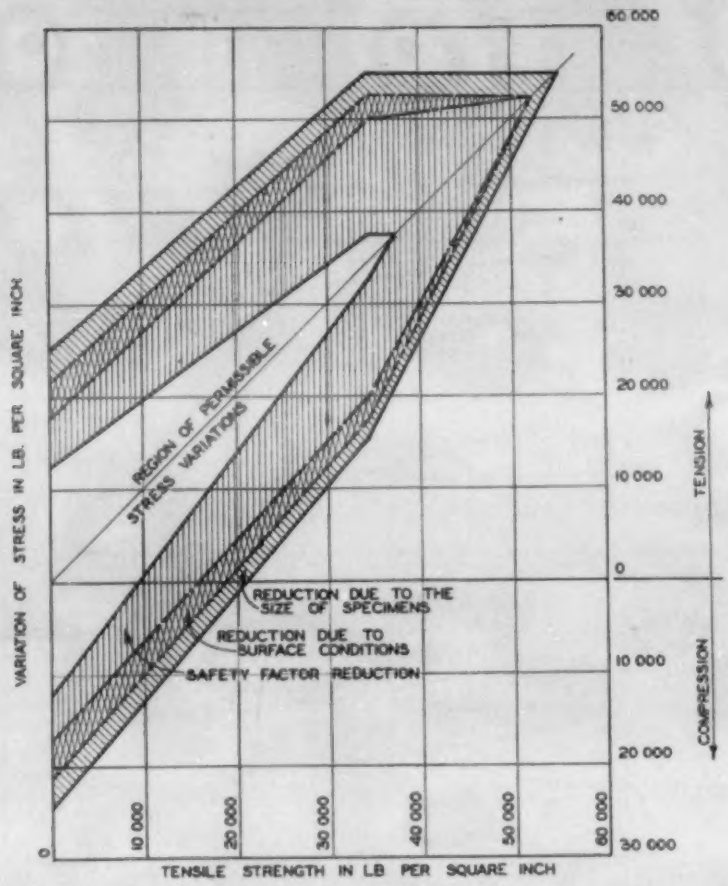

Fig. 9. Fatigue diagram—region of permissible stress variations.

of tests of actual structural members or models of them. This kind of testing cannot be conducted in an ordinary material testing laboratory but must be made in specially equipped laboratories. Since such tests are based on the use of materials the behavior of which has already been determined in ordinary material testing laboratories, the main attention is given to the design of the structural members. The whole problem becomes distinctly an engineering problem that must be solved by the engineer rather than by the metallurgist or material testing expert.

Extended scientifically conducted fatigue tests of this kind were first made in Germany. At present they are conducted in a number of laboratories. Prof. Wilbur M. Wilson is conducting a series of such tests at the University of Illinois at Urbana and Dean S. K. Hollister at Cornell University. Recently considerable progress has been made in the use of vibrators in fatigue testing of actual structures. The results of these tests in many cases can be used reversely to determine the actual stress concentrations at different points of simple structural members.

Riveted Joints

The joints relatively are the most expensive parts of a structure but the action of joints, the distribution of stress, the stress concentrations, etc., are not well known.

If a material possesses a certain fatigue strength, this strength can be fully utilized only if the joints permit such utilization. The fatigue strength determined on material test specimens does not disclose the behavior of the joint even if all elements of the joint are made of the same material. If, as in many cases, a different material is used for the rivets, the conditions become even more complicated. Fatigue strength, stress concentrations, tightness of the joint due to the compression developed by the rivets and the extent to which the rivet fills the hole, the bearing carried by the rivets, all are factors that influence the fatigue strength of a riveted joint. The results of extended tests to determine the pulsating strength of riveted joints made by Graf and Schaechterle are briefly summarized on Fig. 10. In all these tests the number of load applications was limited to two million.

The pulsating strength of the material of the joints determined on specimens polished on all sides was equal to the yield point strength. For specimens polished only at the edges, the pulsating strength was lower. For specimens not polished, with mill scale on, a still lower value of the pulsating strength was obtained. The drilling of a hole in the specimen results in stress concentrations along the edges of the hole, reducing again the pulsating strength. The tight filling of the hole by a rivet reduces the stress concentration and increases the pulsating strength.

The pulsating strength of a specimen with a hole and with two plates riveted to the specimen at both sides represents the maximum pulsating strength which a riveted connection may attain. The pulsating strength of actual riveted joints must be somewhat lower, and depends to a large extent on the friction between the splice plates and the joining plates, which in turn depends on the compression force developed by the rivets. The self-adjusting property of riveted connections is an important advantage which makes the fatigue strength of riveted joints practically independent of the way in which the rivets are distributed. The multiple row riveted joints are as effective as single row joints, provided the same ratio prevails between the tension stress, bearing, and frictional resistance of the different joints.

The best possible utilization of material in a riveted joint may therefore be obtained in a butt joint with splice plates using rivets of such material as will produce the highest compression, and spacing these rivets so as to obtain the tightest possible joint. Any greasing of the contact surfaces, as for instance by painting, will reduce the fatigue strength of a splice joint.

Welded Joints

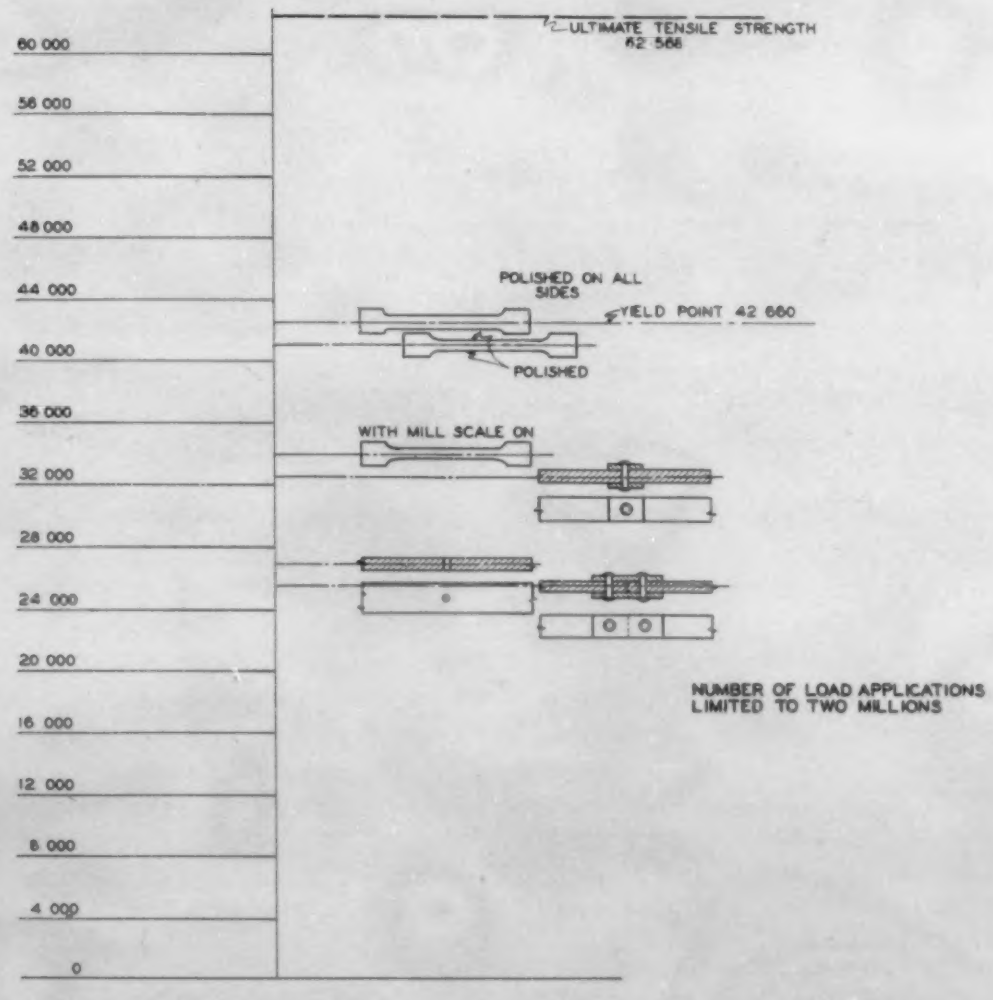
The connections that were most commonly used in structural designs of the past were riveted or

bolted connections, to which at present must be added the welded connections. Welding is rapidly growing in importance in structural designs. The problem of weldability of alloys belongs to the field of the metallurgist; but the manner in which welds are made is a structural engineering problem.

Welded joints do not possess the self-adjusting properties of riveted joints and therefore the fatigue strength of welded joints may vary in exceedingly wide limits, depending on the design of the joints.

The flow of stress and stress concentrations that are responsible for such conditions are illustrated in Fig. 11. In a splice plates butt joint with frontal seams, the flow of stress is changed abruptly when the stress flow is crowded through the seams in order to reach the splice plates. A considerable stress peak must result. By increasing the thickness of the splice plates the stress in the plates may be reduced without however reducing the stress peak at the places where the welding seam connects the jointing members.

In a butt seam joint, only a slight disturbance of the stress flow occurs, resulting in a moderate stress concentration. The different welded connections can be placed between these two limiting cases.



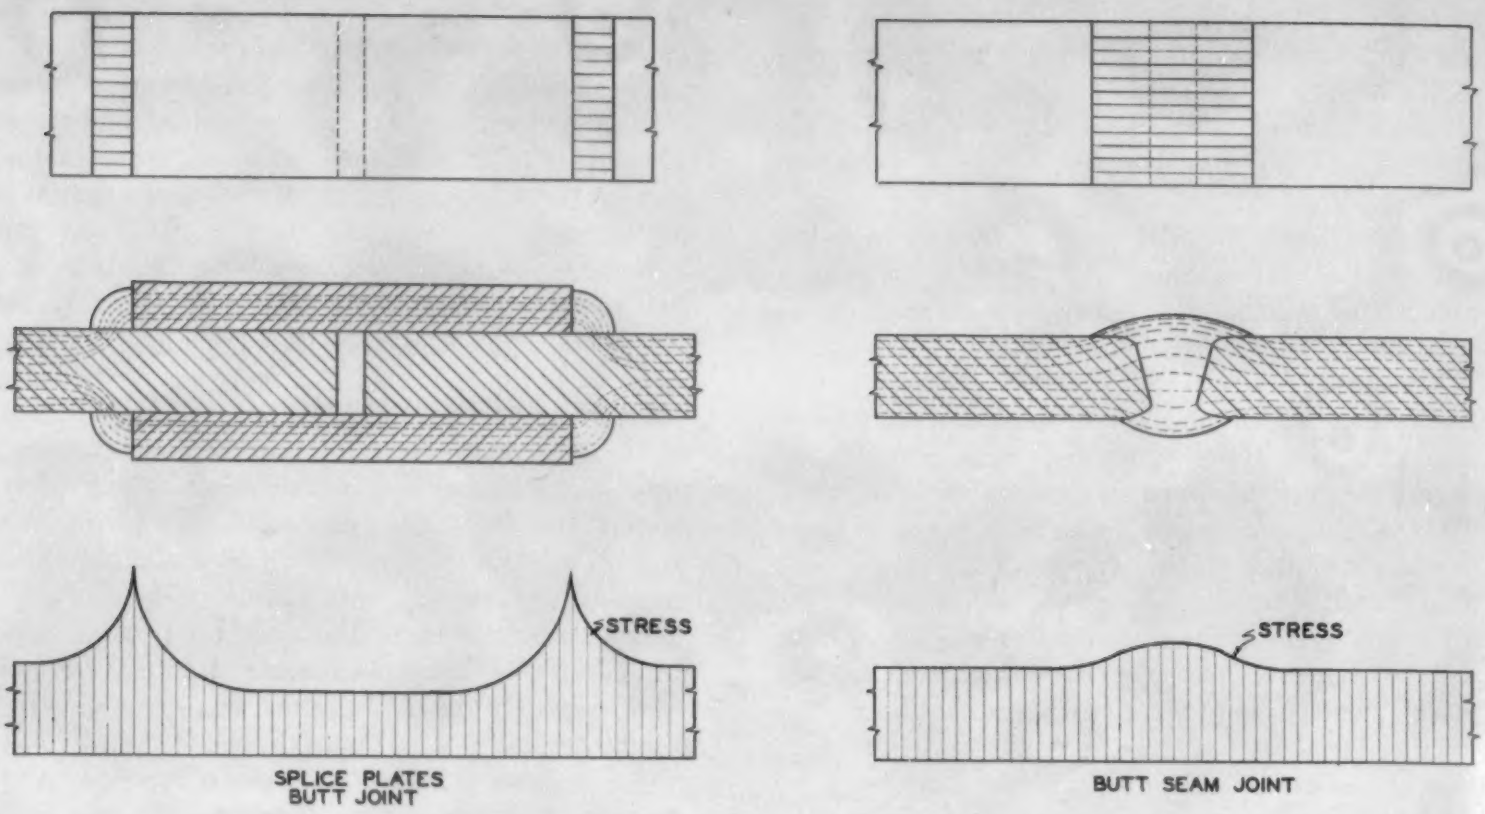
The results of the pulsating strength investigation of welded joints are briefly summarized in Fig. 12. This diagram is combined with the corresponding part of the fatigue diagram of the base material of the joints.

In order to clarify the problem of stress concentrations in different kinds of welded joints, model specimens 1 to 4 were tested. These models are made of solid material. The cross-seam welded to one side of model 2, reduces the pulsating strength of the original specimen 1, due to stress concentrations at the seam, also a certain weakening of the original bar due to the penetration zone of the weld. A seam on both sides, as shown on model 4, reduces the pulsating strength very considerably.

Model 3 represents the conditions of a splice joint, showing the considerable reduction in pulsating strength of such joints due to high stress concentrations.

The highest pulsating strength is attained in the joint 5; it is somewhat higher than 2, the stress

Fig. 10. Pulsating strength of riveted joints.



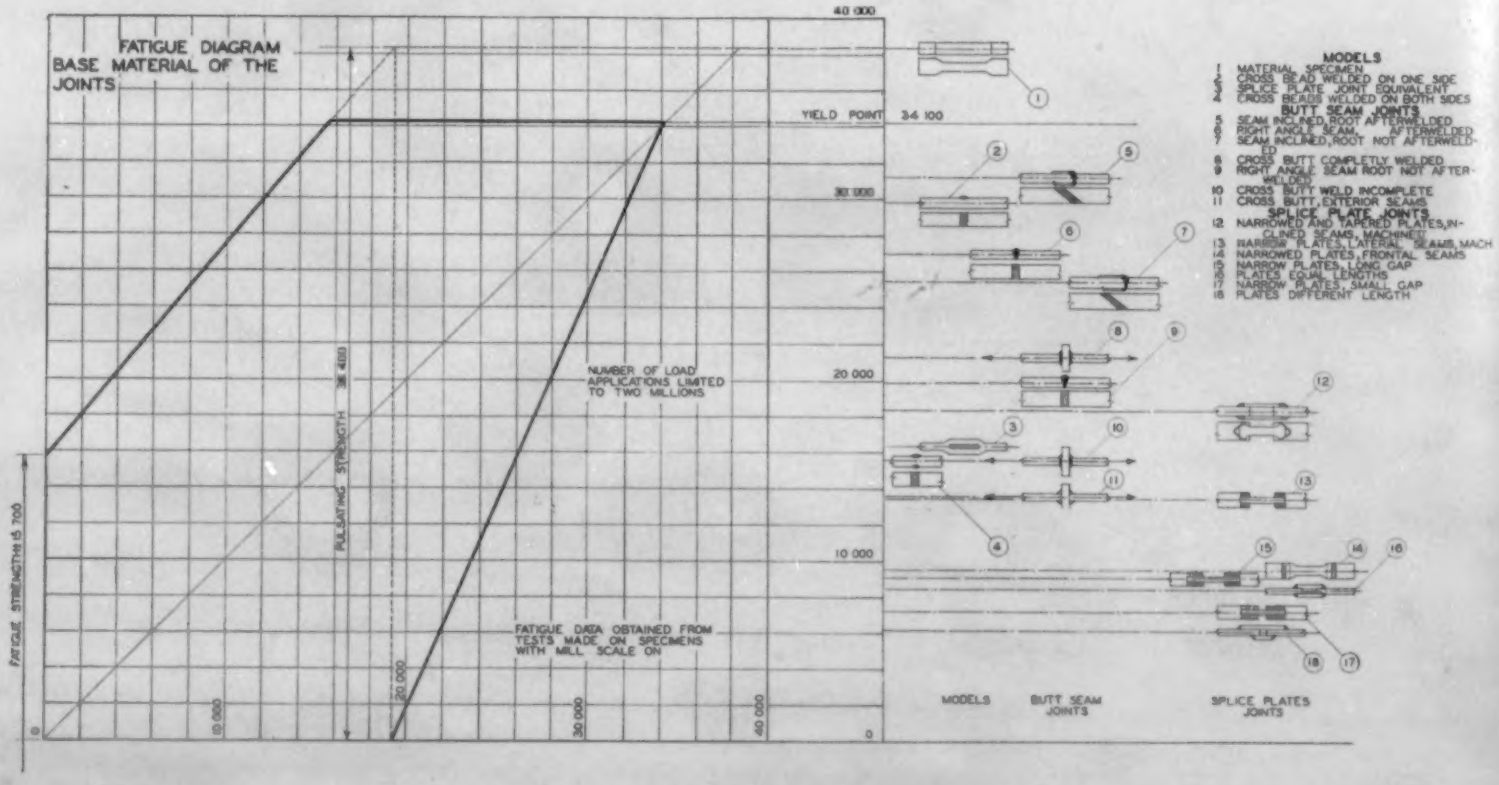


Fig. 11. Flow of stress in welded joints.

Fig. 12. Pulsating strength of welded joints.

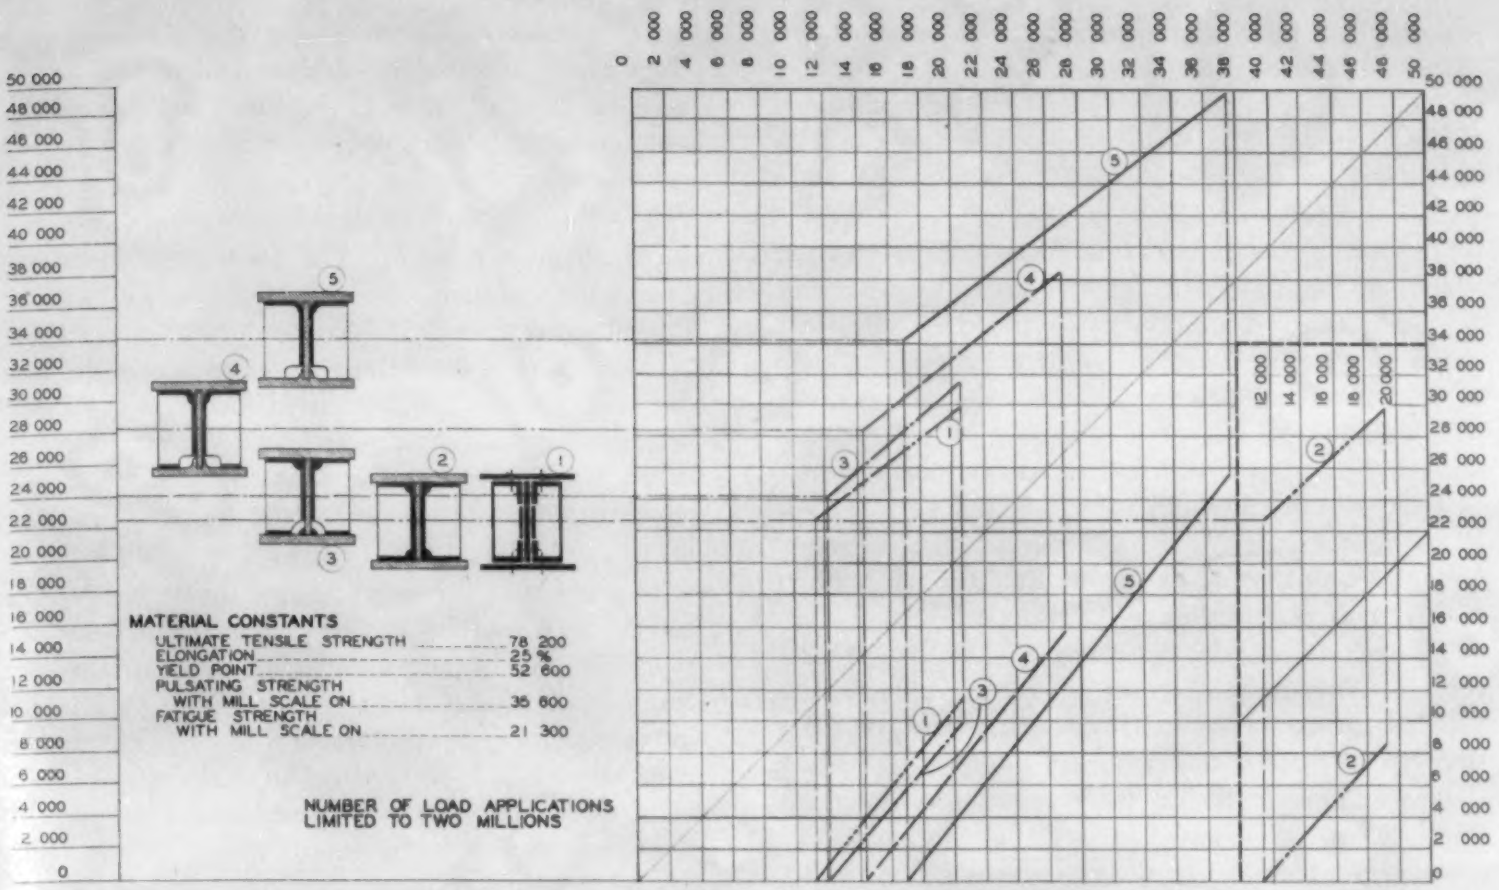

Fig. 13. Pulsating strength of welded and riveted plate girders.

concentrations being reduced due to the inclined seam and the machining and afterwelding of the root of the seam. The pulsating strength is reduced if, in a similar joint with an inclined seam, the root is not machined as shown under 7. The lowest pulsating strength, shown under 9, is exhibited by a right angle butt seam joint, without afterwelding. Cross-butt welded joints are exhibiting the highest pulsating strength, shown under 8, if the connection areas are completely welded; lower pulsating strength, shown under 10, will be obtained if part of the connection area is left open, resulting in increased stress concentrations; the lowest strength of such joints, shown under 11, is obtained if the connection is made by external seams leaving open the whole area of the plate; the high stress concentration occurring in such a joint is obvious.

The splice plate welded joints exhibit the lowest pulsating strength. The strength of the joint shown under 12, in which the stress concentrations are reduced by means of inclined seams, tapered plates and machining of the outstanding ends of the seams, is somewhat higher than in case of model 3. Narrow splice plates joints with lateral seams, shown under 13, 15 and 17, exhibit different pulsating strength. The higher strength shown under 13 is obtained by reducing the stress concentration by means of machining of the seams. The improvement of 15 as compared to 17 is due to a larger gap resulting in a less abrupt change in the stress flow. The lowest pulsating strength is exhibited by frontal seam splice joints 14, 16 and 18. The high stress concentrations of such joints, as shown on Fig. 11, are responsible for these conditions. The narrowed splice plates are improving somewhat the conditions of the joint 14; the joint 18, with splice plates of different length, has the highest stress concentrations, higher than the joint 16 with splice plates of equal length.

The radical difference between riveted and welded joints, and in particular the superiority of butt seam welded joints, and the inferiority of splice plates welded joints is a striking illustration of the importance of properly conducted fatigue tests of structural elements.

Welded and Riveted Plate Girders

The further extension of fatigue investigation leads into the determination of fatigue properties of more complicated structural elements. The results of pulsating strength investigation of welded and riveted plate girders made by Schulz and Buchholtz are briefly summarized in Fig. 13. The pulsating strength of five different girders, made of the same high grade steel and tested in bending, are shown on the left half of the figure; the pulsating strength for different degrees of pulsation are shown on the diagram on the right half of the figure. All girders were similar, having stiffeners at supports and at two points between, at which the loads were applied.

The highest fiber stress was evaluated by using the standard flexure formulas.

Under 1 is shown the pulsating strength of a riveted girder. The welded girder under 2, which is similar to the riveted girder, exhibts the same pulsating strength.

The complicated stress conditions at the meeting planes of the web, stiffener and girder plates result in high stress concentrations; the welding seam penetrates the base material and the penetration zone is weaker as compared with the original material; this weakening is of no importance in compression areas but may be detrimental in tension areas.

The pulsating strength therefore may be increased if, as shown under 3, the stiffener plate weld seams are interrupted so as to permit the straight passage of the web plate seams.

Elimination of the influence of the penetration zone of longitudinal seams by means of specially profiled cover plates still increases the pulsating strength, as shown under 4.

Finally, a remarkable increase of the pulsating strength may be obtained by omitting the cross-weld seams at the tension part of the cover plate, as shown under 5.

The striking superiority of a properly designed welded plate girder if compared with conventional riveted girders is made still clearer by comparing the pulsating strength diagram under 5 with that under 1.

VI. CONCLUSIONS

Until very recently the structural engineer took a purely academic viewpoint with reference to fatigue problems. The idea was that they are of no importance in structural designs and should be considered, if at all, only in the most modern branches of mechanical engineering—the aeronautical and automobile industry.

The trend of engineering development is the same as of all exact sciences. The increase of knowledge brings the different branches of science or engineering closer together. It becomes clearer as time goes on that there is no difference, in so far as the basic design principles are concerned, between the design of a bridge or a railroad car frame, or an automobile, or an airplane body. The only real difference is the limit to which it is economically necessary to go in details and refinements in design and fabrication.

It is obvious, for instance, that under present conditions it would be useless to give a lengthy consideration to fatigue problems in most parts of steel frame building structures. But it is also obvious that in so far as, for instance, bridge trusses, and in particular modern welded bridges, are concerned, no satisfactory design can be made unless proper consideration is given to fatigue problems. The progress in light weight railroad cars, in automobiles and airplanes can hardly be visualized without the most painstaking study of fatigue phenomena. Testing grounds may be a short cut for some time, but more scientific methods are forced upon the designer.

The results of the investigations of metallurgists and material testers must be applied to the elementary parts and to complete engineering structures. Such work was started by designing engineers in structural laboratories, and undoubtedly will be continued, changing gradually the fatigue studies from an interesting academic to an intensely practical subject.

Letters

TO THE EDITOR

Austempering or What

To the Editor: The article on austempering by E. E. Legge in the August issue of METALS AND ALLOYS points out many of the valuable practical applications of this method of heat treatment. It is not, however, generally recognized that the first large-scale use of this system was carried out by the American Chain Co. in 1928 in its study of the mechanical properties of heat-treated wire with particular emphasis on high-strength material for suspension bridges.

In order to study the entire range of quenching in a hot rather than a cold bath, the American Chain Co. carried out, under my direction, an extensive series of tests in which carbon steel of approximately eutectoid composition was quenched in lead, molten salt and hot oil. The phenomena of stable austenite and the control of the austempering process were discovered in the course of this work and a description of a portion of the work, together with photographs of the austempering structures, was published by

Dartrey Lewis in the 119th volume of the British Iron and Steel Institute in 1929 under the title, *"The Transformation of Austenite into Martensite in a 0.8 per cent Carbon Steel."*

The maximum point in combined ductility and tensile strength was determined and the famous but ill-fated, heat-treated bridge wire was prepared by an austempering process. The final commercial failure of this wire was in no way connected with the extremely desirable combination of strength and ductility which resulted from the austempering operation.

The production method used for producing heat-treated bridge wire involved the use of hot oil at about 240 deg. F. rather than molten salt. As this process was described in the paper by Swanger and Wohlgemuth in the *Proceedings of the A. S. T. M.*, Vol. 36, Part II, p. 41, 1936, entitled, *"Failure of Heat-Treated Steel Wire in Cables of the Mt. Hope, R. I., Suspension Bridge,"* the wire was quenched in oil at 240 deg. F. for 90 seconds. Magnetic tests were carried out to determine that at the end of this time the wire was still essentially non-magnetic, soft and ductile. A longer time, however, would result in martensite as would an air cooling from the oil temperature.

In the production line, this substantially austenitic wire was then treated in lead for 18 seconds at 840 deg. F. The resulting structure had mechanical properties very similar to those noted by Mr. Legge for steel of this composition, the particular characteristic being very great ductility as measured by reduction of area or the bend test. In our case the wire could be wrapped around a mandrel of its own diameter. The occasional failure to wrap at this diameter was associated with defective surface rather than defective structure.

The fact that the method was used in large-scale production before the complete investigation by Davenport and Bain, does not in the least detract from the importance of this classic investigation. It merely illustrates that an empirical development for production purposes usually precedes rather than follows, a complete laboratory investigation of a new field. As has been mentioned before, the patenting process itself is merely an early practical use of one region of the austempering technique.

It might also be of interest in this connection to note that a very considerable amount of work was done in 1929 in attempting to apply this method of heat treatment to the preparation of ball-bearing products but without any marked improvement in the fatigue life of such products.

Corrosion of Zinc

TO THE EDITOR: The article by Messrs. Anderson and Fuller on the "Corrosion of Zinc" published in the September number of METALS AND ALLOYS has interested me very much because of some work I have done using X-rays on the corrosion products from galvanized sheets exposed to the atmosphere under various conditions.

I have found that the products are mainly zinc oxide, and basic zinc carbonate. Under certain conditions I have obtained a corrosion product containing a very large amount of zinc hydroxide, together with zinc oxide. Anderson and Fuller state on page 285, left column, 7 lines below the Note, that the initial corrosion product might be zinc hydroxide although it has decomposed into oxide before X-ray examination. This zinc hydroxide was apparently stable.

In the summary the authors state that the "composition of the water corrosion product was found to be $4\ ZnO\ .\ CO_2 4H_2O$" which formula has been arrived at by chemical analysis. The pattern shown in the Table under "Formed by Air Corrosion of Zinc" resembles closely interplanar spacings and relative intensities of $2\ ZnCO_3.\ 3Zn(OH)_2$[1]. This formula has been checked by crystal analysis[2] which would make it a better criterion than just chemical analysis. The authors have analyzed basic zinc carbonates (page 284) with the formula $5\ ZnO.2CO_2.4H_2O$, which, rearranged, becomes $2\ ZnCO_3.3Zn(OH)_2.H_2O$. It would be interesting to know on what grounds Messrs. Anderson and Fuller give preference to the formula $4\ ZnO.CO_2.4H_2O$.

F. R. MORRAL,
Research Metallurgist.

A Reply by the Authors

We are very glad indeed to learn of Dr. Morral's interest in our work on the corrosion products of zinc. It is not quite clear to us just what Dr. Morral means by a stable zinc hydroxide. It is probable that the initial product of aqueous corrosion of zinc at normal temperatures is the hydroxide. On drying to a point suitable for handling in the vacuum required in the electron diffraction camera, this product evidently reverts to the oxide form. It is difficult for us to conceive of a stable zinc hydroxide under conditions of drying.

The choice of a formula to express the composition of basic zinc carbonate is apparently not clear-cut. Our expression of the formula as $4ZnO\ .\ CO_2\ .\ 4H_2O$ was merely an attempt to express the ratio of zinc oxide, carbon dioxide and water which we found by chemical analysis. We believe it is fully explained in the paper that since the production of the basic carbonate takes place by the production first of zinc oxide and the later carbonation of this material, a wide range of possible carbon dioxide contents is possible depending upon how deeply the carbonation has penetrated into the individual particles of zinc oxide. The precipitated basic carbonate to which the formula $5ZnO\ .\ 2CO_2\ .\ 4H_2O$ was given actually had a higher CO_2 content than the corrosion product to which the formula $4ZnO\ .\ CO_2\ .\ 4H_2O$ was assigned. The difference between the two to our minds resides in the probability that the corrosion product still contained some uncarbonated zinc oxide.

E. A. ANDERSON and M. L. FULLER.

A "Bourbon" Spring

Note in METALS AND ALLOYS, Vol. 10, July 1939, page MA 396:

A pressure gage with "bourbon" spring!

W. D. WASHBURN

The Solvay Process Co.
Hopewell, Va.

EDITORIAL *(Continued from page 357)*

at the rate indicated by the activity of the latter part of 1939!

The metal industries have enjoyed much the same degree of long-awaited activity as have the chemical industries, and as a result, the technical staffs have been so busy with production problems that many plans for development of improvements and of new products have been laid on the shelf. In six months the executives who have ordered or approved this hiatus may wish they hadn't, for there may be a slump in which the demand for the old-line products again drops to depression levels. At that time it would be very nice to have something better to offer.

Until the clammy hand of the present administration is definitely pried loose from the neck of private enterprise, a continued upward trend with no sudden slumps, can be expected only by incurable optimists.

Since funds for development and research are available in a period such as this, the only reason why a hiatus in their prosecution need intervene, is lack of man power. We hear of many interrupted projects in the technical laboratories of industry because of lack of man power through diversion to what momentarily appear more pressing problems. You can't go out and hire development and research men to take up these problems and expect them to produce results in a few days or months. Real problems aren't solved by people who haven't lived with them a while. The time lost by diversion of the energies of those who have been living with them can never be made up.

So it seems to us that when the next slump comes, those who will be in the best shape to meet it are those who had already so divorced their research and development crew from the production crew that the former were not diverted in their efforts, but went right on with the problems whose solutions are needed to build the bulwark of lower costs and better products that will insure sales even in a slump.

When it actually starts to rain, it's too late to buy the umbrella of previous development work and it's not effective to scold the poor provider at that time. It is in order to sound the word of warning when the sun is shining and when only negligence and not lack of funds prevents laying in the umbrella.

A good New Year's resolution for 1940 would be to set up research and development on the organization chart as the one group to be kept intact, undiverted and preferably augmented. That is the most practical way of getting ready for the time when the clouds gather again. And who can feel confident that they won't?—H.W.G.

Powder Metallurgy

Many of those who attended the National Metal Exposition in Chicago were impressed as well as enlightened as to the progress which is rapidly being made in powder metallurgy. Three organizations which are active in this field displayed in their booths not only various metals in powder form but also some of the many products which are being made commercially or are being experimented on. The revelations were rather astounding and decidedly impressive. The alloys involved are numerous and the products made were varied in nature and applications.

One fact was evident—the probability in the near future of the production in this country of a pure powdered iron on a fairly large commercial scale. Details of this development are not yet available but its importance was not minimized. It was emphasized by those interested that some highly important products are possible using a relatively pure iron as a base.

Powder metallurgy has its limitations of course and it is not claimed to be a panacea. Undoubtedly it has a brilliant future and developments in this field will be closely followed.—E.F.C.

Tin at 5 Cents a Pound!

To the Editor: From the *N. Y. Times,* Sunday, Nov. 12.

TIN REACTS SHARPLY

The great percentage decline has been in tin, which in the middle of September reached 7½ cents a pound and is now back to 5 cents. One of the reasons tin shot up is the fact that it is an imported commodity, but enlarged export quotas served to allay fears of a possible shortage.

Well, a good 5c pound of tin would be something.—H.W.G.

A New Corrosion Concept?

A bulletin put out by a commercial company states:

"Stainless steel is unquestionably the best material for floats as it is not affected by most acids or chemicals . . . etc. Further, it is non-magnetic, thus avoiding pitting due to electrolysis, should this condition be present."

AND JUST WHAT IS DOWMETAL ?

DOWMETAL* is the trade name for a group of magnesium alloys all containing 90-98% magnesium. Within this range, specific compositions have been developed to meet the varying needs of industry.

Magnesium is an elemental metal and, just as iron, copper, tin, zinc, and aluminum have their basic uses and functions in the metal working fields, so has magnesium. Where *extreme* lightness (magnesium is ⅓ lighter than any other metal commonly used) plus great strength and durability are required, magnesium alloys meet the specifications as no other metal can. They can be fabricated by all common methods—rolling, forging, welding, extruding, die casting, sand casting, and stamping; and are the easiest of all metals to machine.

DOWMETAL'S use in both single unit and mass production operations allows manufacturers to produce products that are easier to handle, cut power, time and labor requirements or reduce dead, useless weight. These advantages are reflected in the enthusiastic acceptance of magnesium alloys.

Visit the Dowmetal Booth at the National Metal Congress and Exposition in Chicago, October 23 to 27.

Write today for the booklet, "Industry's Lightest Structural Metal." It is a complete and concise discussion of magnesium alloys—their properties, specifications and fabrication. It illustrates graphically the wide range of applications in which industry is taking advantage of DOWMETAL'S extreme lightness.

WM. P. WOODSIDE
PRESIDENT—A.S.M.

J. P. GILL
VICE-PRESIDENT—
A.S.M

International Amphitheatre — Chicago — This will house the National Metal Exposition

IN 1935, OR FOUR YEARS AGO, the National Metal Congress was held in Chicago. This year, the twenty-first annual Congress will again meet in Chicago in the same locations as in 1935. This year the Congress is scheduled for Oct. 23 to 27, with the Palmer House as the headquarters and the International Amphitheatre housing the National Metal Exposition.

Participating Societies

As in recent years, there will be four technical societies participating in the Congress—the American Society for Metals, the American Institute of Mining and Metallurgical Engineers, the American Welding Society, and the Wire Association. The A. S. M. is the sponsor society.

These four organizations have scheduled technical sessions during the Congress. Some 135 papers and lectures by leading metallurgists, metallurgical engineers, and prominent industrialists and scientists will be delivered. Each society has some special feature in its programs. The tentative list of papers will be found on other pages.

The Exposition

As in 1935, the large metal exposition will be held in the International Amphitheatre. It is expected that this year's "steel show" will exceed in size and scope any previous one. On other pages will be found a list of the exhibitors and the floor plan of the amphitheatre.

Special Lectures

Four years ago, there was instituted as a regular feature, a series of educational lectures. This year, E. C. Bain, of the U. S. Steel Corp., will deliver a series as will also Prof. G. M. Enos of the University of Cincinnati. These lectures have proved a magnet in the past and those this year will be of a high order. Another attraction is the Campbell Memorial lecture by E. S. Davenport of the U. S. Steel Corp. The A. W. S. and the A. I. M. E. also have lectures scheduled.

A special program of plant visitations has been arranged.

A 10-Year Review

In place of publishing a detailed list of the exhibitors and what they will exhibit, we are substituting a series of reviews of 10 years of metallurgical progress. These follow the page of the list of the exhibitors. We commend their careful reading for they are contributed by our Editorial Advisory Board, the staff and a few other leaders in certain fields. One of the members of the Board, O. W. Ellis, was prevented from contributing by absence in Europe.

Appended to each review is a partial list of related articles which have appeared in METALS AND ALLOYS in the last decade.

Technical Program of the

American Society for Metals

ONE OF THE LEADING EVENTS of the National Metal Congress is the annual technical program of the sponsor society, the American Society for Metals.

The program for this year's congress is made up of about 50 papers by many of the leading American metallurgists. The sessions commence on Monday Oct. 23, and continue each day through Friday, Oct. 27. Some simultaneous sessions have been scheduled for certain days. The morning sessions are to be held at the Palmer House, the headquarters, and the afternoon sessions at the National Metal Exposition.

A feature of the convention is a symposium on "Precipitation Hardening." Another highlight is a series of afternoon lectures by E. C. Bain, assistant to the vice president in charge of research, U. S. Steel Corp., Pittsburgh. Prof. G. M. Enos, University of Cincinnati, Cincinnati, Ohio, will deliver a series of evening lectures on macroscopic, and other visual, examination of steel.

The outstanding feature of the week is the Campbell Memorial Lecture by E. S. Davenport, U. S. Steel Corp. Research Laboratory, Kearny, N. J.

The papers, tentatively scheduled to be delivered during the convention, are as follows:

"Impact Properties of Some Low Alloy Nickel Steels at Temperatures Down to —200 Deg. F.," by T. N. Armstrong and A. P. Gagnebin, International Nickel Co.

"The Effect of Titanium on the Macro-Structure and Grain-Coarsening Temperature of Forging Steel," by G. F. Comstock, Titanium Alloy Mfg. Co.

"Introductory Study of the Nitriding of Hardened High-Speed Steel by the Use of Molten Cyanides," by J. G. Morrison, Landis Machine Co., and J. P. Gill, Vanadium-Alloys Steel Co.

"Some Practical Notes on High-Speed Steel Forgings," by W. H. Wills, Allegheny-Ludlum Steel Corp.

"The Stress-Strain Characteristics of the Torsion Impact Test," by O. V. Greene and R. D. Stout, Carpenter Steel Co.

"The Influence of Magnetic Fields on Damping Capacity," by E. R. Parker, General Electric Co.

"The Interrelation Between Stress and Strain in the Tensile Test," by E. J. Janitzky and M. Baeyertz, Carnegie-Illinois Steel Corp.

"The Fatigue Resistance of Steel as Affected by Acid Pickling," by G. L. Kehl and C. M. Offenhauer, Lehigh University.

"Creep Rates From Tests of Short Duration," by J. J. Kanter and E. A. Sticha, Crane Co.

"Characteristics of 5 and 7 Per Cent Chromium Steels with Varying Molybdenum and Vanadium Content," by W. G. Hildorf, Timken Roller Bearing Co., and C. L. Clark and A. E. White, University of Michigan.

"Stress Corrosion-Cracking of the Austenitic Nickel Steels and Its Industrial Implications," by J. L. Miller, Armour Institute of Technology, and J. C. Hodge, Babcock & Wilcox Co.

"Ferromagnetic Austenite," by L. P. Tarasov and E. R. Parker, General Electric Co.

"An Analysis of Machinability Data From Cold-Finished and Heat-Treated S.A.E. 1045 Steel," by O. W. Boston and W. W. Gilbert, University of Michigan.

"A Discussion of Lead-Bearing Steel," by F. J. Robbins and G. R. Caskey, Bliss & Laughlin, Inc.

"Precipitation Hardening Characteristics of High Purity Aluminum-Copper and Aluminum-Copper-Iron Alloys," by H. Y. Hunsicker, Aluminum Co. of America.

"Drawing of Aluminum," by L. J. Weber and J. T. Weinzierl, the Aluminum Cooking Utensil Co.

"Annealing of Low Carbon Rimmed, Aluminum-Killed and Silicon-Killed Steels," by W. P. Wallace, Columbia Steel Co., and R. L. Rickett, U. S. Steel Corp.

"The Prevention of Flakes by Holding Railroad Rails at Various Constant Temperatures," by R. E. Cramer and E. C. Bast, University of Illinois.

"Selection of Steel and Heat Treatment for Spur Gears," by H. B. Knowlton and E. H. Snyder, International Harvester Co.

"Time Quenching," by J. L. Burns and Victor Brown, Republic Steel Corp.

"A Test Method for the Evaluation of Aqueous Quenching Media for Steel Hardening," by F. W. Trembour and Howard Scott, Westinghouse Electric & Mfg. Co.

"Hardenability Variations in Alloy Steels: Some Investigations with the End-Quench Test," by G. T. Williams, Cleveland Tractor Co.

"A Hardenability Test for Shallow Hardening Steels," by W. E. Jominy, General Motors Corp.

Annual Meeting and Campbell Memorial Lecture, by E. S. Davenport, U. S. Steel Corp., Kearny, N. J.

"The Effect of Hardness and of Temperature on the Strength, Ductility, and Toughness of a Heat-Treated Carbon Steel," by S. W. Lyon, University of Illinois.

"Hardness Characteristics of Some Median Carbon S.A.E. Steels," by P. Kalin and C. H. Lorig, Battelle Memorial Institute.

"The Accelerating Effect of Certain Metallic Elements on Graphitization," by H. A. Schwartz, V. Fiordalis, J. L. Fisher, J. F. Shuman and M. F. Trinter, National Malleable & Steel Castings Co.

"Transformation of Austenite on Quenching High Purity Iron-Carbon Alloys," by T. G. Digges, National Bureau of Standards.

"Kinetics of the Austenite-Martensite Transformation in Steel," by A. B. Greninger and A. R. Troiano, Harvard University.

"The Mechanical Properties of the Isothermal Decomposition Products of Austenite," by M. Gensamer, E. B. Pearsall and G. V. Smith, Carnegie Institute of Technology.

"The Spheroidizing of Steel by Isothermal Transformation," by P. Payson, W. Hodapp and J. Leeder, Crucible Steel Co. of America.

"Bright Hardening of Tool Steels Without Decarburization or Distortion," by J. R. Gier and Howard Scott, Westinghouse Electric & Mfg. Co.

"Hardness Conversion Relations for Hardened Steels," by H. Scott and T. H. Gray, Westinghouse Electric & Mfg. Co.

"Hardenability Studies on Tool Steels," by A. J. Scheid, Jr., Columbia Tool Steel Co.

"Nickel-Tungsten System," by W. P. Sykes and F. H. Ellinger, General Electric Co.

"The Effect of Humidity of Air on the Oxidation of a Low Carbon Steel," by C. A. Siebert, University of Michigan, and H. G. Donnelly, Wayne University.

"Heat Etching as a Means of Revealing Austenite Grain Size," by M. J. Day and J. B. Austin, United States Steel Corp.

"The Tempering of High-Speed Steels," by Morris Cohen and P. K. Koh, Massachusetts Institute of Technology, Cambridge, Mass.

"Introduction to Precipitation Hardening," by Zay Jeffries, General Electric Co., Cleveland.

"The Application of Solid Solution and Precipitation Hardening Effects in Aluminum Alloys," by L. W. Kempf, Aluminum Co. of America.

"Precipitation-Hardening of High Purity Binary and Ternary Aluminum-Copper Alloys," by W. L. Fink, D. W. Smith and L. A. Willey, Aluminum Co. of America.

"Precipitation Hardening in the Heavy Alloys," by W. P. Sykes, General Electric Co.

"Age-Hardening Copper Alloys," by D. K. Crampton, Chase Brass & Copper Co.

"Age-Hardening of a Copper-Cobalt and a Copper-Iron Alloy," by R. B. Gordon, Westinghouse Electric & Mfg. Co., and M. Cohen, Mass. Inst. of Tech.

"Precipitation Hardening in Nickel-Base and Precious Alloys," by N. B. Pilling and A. M. Talbot, International Nickel Co., Bayonne, N. J.

"Aging in Iron and Steel," by R. L. Kenyon and R. S. Burns, American Rolling Mill Co.

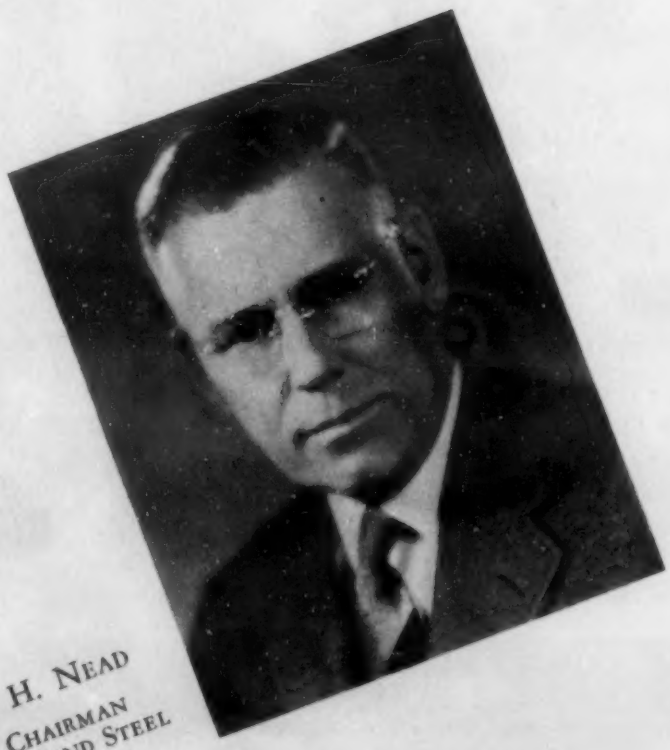
"The Role of Strain in Precipitation Reactions in Metals," by R. H. Harrington, General Electric Co.

"The Mechanism of Precipitation Hardening—The Theory of Age-Hardening," by R. F. Mehl, Carnegie Institute of Technology.

Heat Treaters:—while at the Show discuss your furnace atmosphere control problems with Hayes "Certain Curtain" engineers

World's leading ELECTRIC CERTAIN CURTAIN FURNACES Tool Furnace

BOOTH NO. B-102, NATIONAL METAL CONGRESS



Selected on the basis of RESULTS by an overwhelming majority of leading tool producers and tool users, Hayes "Certain Curtain" furnaces are today definitely "tops" in the field of controlled atmosphere heat treatment. We extend a cordial invitation to visit our exhibit at the Show.

Technical Program of the

Metal Divisions of the A.I.M.E.

J. H. NEAD
CHAIRMAN
IRON AND STEEL
DIVISION

ROBERT H. LEACH
CHAIRMAN
INSTITUTE OF METALS
DIVISION

AN EXCELLENT PROGRAM of some 22 technical papers has been prepared for the sessions of the iron and steel and the nonferrous divisions of the American Institute of Mining and Metallurgical Engineers. The various sessions commencing on Monday and ending on Wednesday, Oct. 25, during the Congress, are to be held at the Blackstone Hotel.

The annual autumn joint dinner of the two divisions will be held Tuesday evening, Oct. 24, at which C. M. White, vice president in charge of operations, Republic Steel Corp., Cleveland, will be the principal speaker.

The technical program is tentatively as follows:

"A Laboratory Study of the Reactions Occurring Between Molten Zinc Alloys and Pressure Die Casting Equipment," by E. A. Anderson, Gerald Edmunds and C. W. Siller, The New Jersey Zinc Co.

"A High Strength Silicon Brass Die Casting Alloy," by Alan U. Seybolt and B. W. Gonser, Battelle Memorial Institute.

"The Pitting of Stainless Steels," by H. H. Uhlig, Mass. Inst. of Tech.

"Data on Pit Focii," by R. Buehl and John Wulff, Mass. Inst. of Tech.

"Beneficial Effects of Zirconium in Cast Nickel-silicon Bronzes," by F. R. Hensel, E. I. Larsen and A. S. Doty, P. R. Mallory Co., Inc.

"A Study of the Distribution of Structural and Physical Characteristics Through the Bodies of Large Castings of Gun Metal," by A. A. Bradd, College of the City of New York.

"A Study of the Distribution of Structural and Physical Characteristics Through the Bodies of Large Castings of Red Brass, by Allen M. Rahm, College of the City of New York.

"Magnetic Analyses of Transformations in a Cold Worked 18-8 Alloy," by R. Buehl and John Wulff, Mass. Inst. of Tech.

"A New Instrument for the Magnetic Determination of Carbon in a Steel Bath," by H. K. Work and H. T. Clark, Jones & Laughlin Steel Corp.

"An Apparatus for Determining the Thermo-magnetic Behavior of Slags and Some Preliminary Results Obtained With It," by B. A. Rogers and K. O. Stamm, U. S. Bureau of Mines.

"The Structure of Aluminum After Compression," by Charles S. Barrett and Leonard H. Levenson, Metals Res. Lab., Carnegie Institute of Tech.

"Recrystallization of Lead," by Paul A. Beck, American Smelting & Refining Co.

"Tensile Deformation of Critically Oriented Brass Crystals," by H. L. Burghoff, Chase Brass & Copper Co.

"The Solubility of Nitrogen in Molten Iron-silicon Alloys," by J. C. Vaughan and John Chipman, Mass. Inst. of Tech.

"Studies of Erosion of Guns," by Peter R. Kosting, Watertown Arsenal.

"The Constitution and Microstructure of Copper-rich Silicon Copper Alloys," by Cyril Stanley Smith, American Brass Co.

"The Alpha Solubility Limit and the First Intermediary Phase in the Copper-silicon System," by A. G. H. Anderson, Phelps Dodge Corp.

"A Simple Method of Thermal Analysis Permitting Quantitative Measurements of Specific and Latent Heats," by Cyril Stanley Smith, American Brass Co.

"Desulphurization of Pig Iron with Calcium Carbide," by C. E. Wood, E. P. Barrett and W. F. Holbrook, Blast Furnace Studies Section, Met. Div. Bureau of Mines.

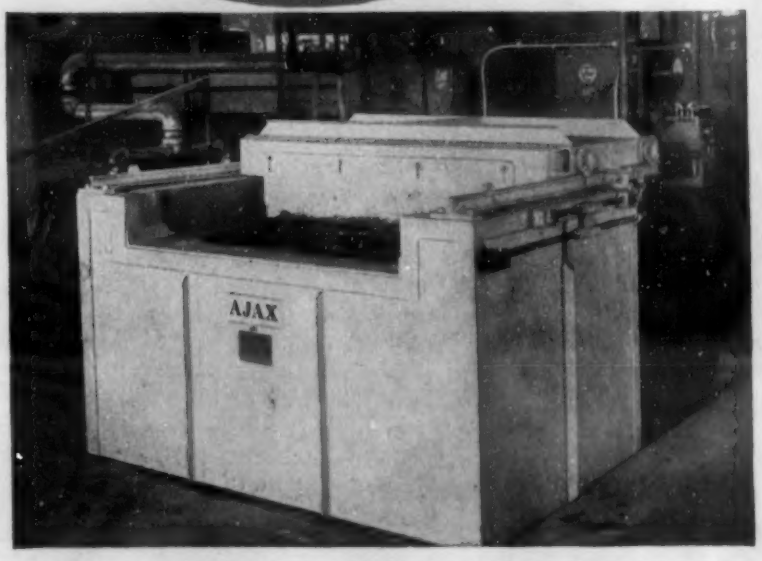
"The Reduction of Iron Ores Under Pressure by Carbon Monoxide," by Michael Tenenbaum and T. L. Joseph, Univ. of Minn.

"Graphitization of Cementite in Cupola White Iron," by N. A. Ziegler, W. L. Meinhart and A. J. Deacon, Crane Co.

"Tensile Properties of Rolled Magnesium Alloys, I. The Binary Alloys with Aluminum, Antimony, Bismuth, Cadmium, Copper, Lead, Nickel, Silver, Thallium, Tin, and Zinc," by John C. McDonald, The Dow Chemical Co.

"Copper Embrittlement, IV," by L. L. Wyman, General Electric Co.

"The Effect of Composition Upon the Physical and Chemical Properties of 10K Gold Alloys," by Tracy C. Jarrett, American Optical Co.



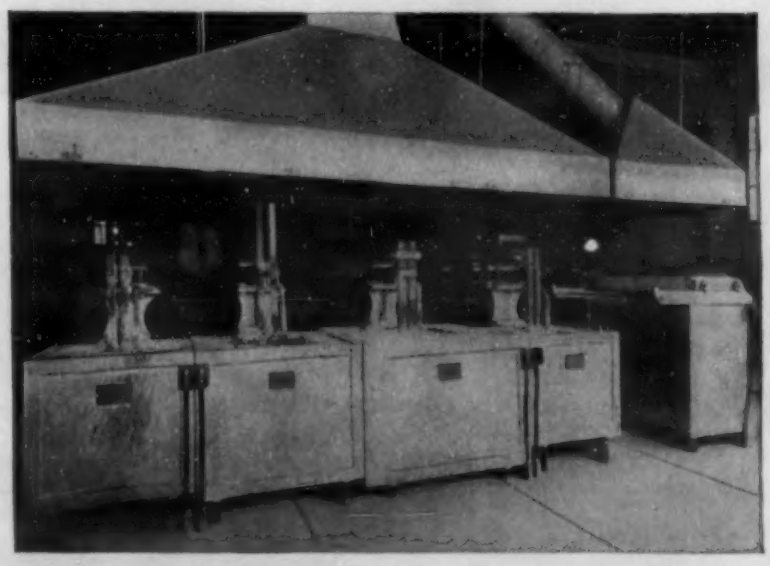
AJAX-HULTGREN Salt Bath FURNACE

ADOPTED DURING PAST THREE YEARS BY

THE LEADING COMPANIES OF THESE KEY INDUSTRIES

- AIR CONDITIONING
- ALUMINUM
- AUTOMOBILE
- AUTOMOBILE PARTS
- AVIATION
- BOLT & NUT
- BUSINESS MACHINE
- CHAIN
- CUTTING TOOL
- DENTAL TOOL
- ELECTRIC METER
- ELECTRIC REFRIGERATORS
- FARM IMPLEMENTS
- GEAR
- HARDWARE
- JEWELRY
- MACHINE TOOL
- MAGNETO
- MOTOR TRUCK
- PRECISION INSTRUMENTS
- SET SCREW
- SMALL ARMS
- SMALL MOTORS
- SMALL TOOLS
- STEEL DIE
- STERLING SILVER
- TEXTILE MACHINERY
- TRACTOR
- WASHING MACHINE
- WROUGHT BRASS
- WIRE

Heats from the inside out.
Pot Life 10 to 20 times longer.
Electric power costs are less than gas or oil costs.
Automatic stirring action insures absolute temperature uniformity in bath.
No scaling, oxidation or decarburization.



AJAX-HULTGREN Batch type Carburizing Furnace used for carburizing steel airplane parts and plate dies.

Battleships or household appliances, airplanes or automobiles . . . . in heat treating the vital parts of all products, Ajax-Hultgren Furnaces are improving production in plants all over the country and earning their own cost many times over with their economical operation.

The patented internal heating principle, coupled with the automatic stirring action of the bath, assures absolute temperature uniformity throughout the entire heat treating range — from 300 F. to 2400 F. Let one of our technical staff explain to you why the AJAX-HULTGREN Furnace has replaced hundreds of fuel fired furnaces during the past three years for - - - carburizing, hardening, tempering, annealing, heat treating aluminum alloys, hardening high speed steel tools, brazing non-ferrous and ferrous assemblies, heating bars for forging, etc.

If you must have maximum uniformity in your heat treating, let us show you how the Ajax-Hultgren Salt Bath Furnace can give it to you — plus a sizeable reduction in heat treating costs.

Battery of Five AJAX-HULTGREN Furnaces for hardening and drawing high speed steel tools.

Technical Program of the

American Welding Society

A TECHNICAL PROGRAM of about 55 papers has been prepared for the 20th annual meeting of the American Welding Society during the National Metal Congress. All sessions, running from Monday to Friday inclusive, Oct. 23 to 27, will be held at the Stevens Hotel, the headquarters. Important events include sessions on Fundamental Research, Flame Hardening and Hard Surfacing, Resistance Welding and so on. There are many simultaneous sessions.

Two evenings are devoted to conferences on Industrial Research and on Fundamental Research, respectively. The annual banquet will be on Thursday evening, Oct. 26. The technical papers follow:

"Welded Structures Under the Bureau of Yards and Docks, U. S. Navy," by C. A. Trexel, Bureau of Yards and Docks, Navy Department.

"Bonneville Dam Presents Varied Use of Welding," by Paul L. Heslop and Fred T. Downing, Corps of Engineers, U. S. Army.

"Some Aspects of the Welding of Alloy Steels," by H. J. French and T. N. Armstrong, International Nickel Co.

"An Investigation of the Spot Welding of Automobile Grade Mild Steel," by W. F. Hess and R. A. Wyant, Rensselaer Polytechnic Institute.

"Failure of Aluminum Subjected to Combined Stresses," by Joseph Marin, Rutgers University.

"Fatigue Tests of Welded Joints in Structural Plates," by W. M. Wilson and A. B. Wilder, University of Illinois.

"Welding Tubing for the Automotive Industry," by G. C. Gridley, Mechanics Universal Joint Division, Borg-Warner Corp.

"Machine Welded Sheet Metal Parts for Enameling," by Joseph C. Lewis, Associated Engineers, Inc.

"Automatic Oxy-Acetylene Welding of Oil Floats," by H. E. Lerner, Taylor Sales Engineering Co.

"Reactions in Arc Welding," by R. David Thomas, Jr. and F. H. Rhodes, Cornell University.

"Arc Welding in Controlled Atmospheres," by G. E. Doan, Lehigh University.

"The Effect of Alloying in Metallic Arc Welding," by R. W. Emerson, Westinghouse Electric & Mfg. Co.

"Manganese in Rutile-Type Coated Steel Electrodes," by E. G. Enck, Foote Mineral Co.

"Creep Tests of Arc Welded Low Carbon Steel," by N. F. Ward, University of California.

"Use of Steel Castings and Rolled Steel Plate in Welded Fabrication," by H. J. Shiffli and Emil Krecji, American Steel Foundries.

"Plate Edge Preparation for Welding," by H. E. Rockefeller, The Linde Air Products Co.

"Flow of Materials in Production Welding," by W. W. Petry, Cincinnati Milling Machine Co.

"Welding Heavy Presses," by L. J. McDonough and J. R. Henry, Clearing Machine Corp.

"Further Studies of the Spot Welding of Low Carbon and Stainless Steels," by W. F. Hess and R. A. Wyant, Rensselaer Polytechnic Institute.

"Application of Proximity Effect to Welding," by E. Bennett, University of Wisconsin.

"Contact Resistance," by F. J. Studer, Union College.

"Weld Inspection by Means of Trepanned Plugs," by W. T. Tiffin, University of Oklahoma.

"Welding of Copper," by A. P. Young, Michigan College of Mining and Technology.

"The Fabrication of Road Building Equipment," by L. L. Burger, La Plant-Choate Mfg. Co., Inc.

"Designing Construction Machinery for Production by Welding," by H. C. Hettelsater, Harnischfeger Corp.

"Cutting and Welding Stainless Clad Steel," by W. B. Keelor, Farwell Metal Fabricating Division, Farwell, Ozmun, Kirk & Co.

"Large Equipment Fabrication," by Leslie McPhee, Whiting Corp.

"Flame Hardening the Way Surfaces of Machine Tools," by Fred C. Dull, the Monarch Machine Tool Co.

"Hard Facing by Fusion Welding," by T. B. Jefferson, Marine Design Section, War Department.

"Flame Treating," by J. H. Zimmerman, the Linde Air Products Co.

"Flame Hardening From the Standpoint of the Commercial Heat Treater," by W. G. Hamilton, Accurate Steel Treating Co., Inc.

"Some Applications of the Resistance Welding Process," by C. L. Pfeiffer, Western Electric Co.

"Precision Welding by the Resistance Method," by E. J. Bates, G. J. Oswald and R. L. Haus, the National Cash Register Co.

"Spot Welding of Aluminum," by R. Kauffmann, Aluminum Francais.

"Some Studies of Flash Welding," by M. G. Yatsevitch, Watertown Arsenal.

"Welding of Boilers and Pressure Vessels," by R. T. Kernoll, Edge Moore Iron Works.

"Oxy-Acetylene Welding of Red Brass Pipe," by A. N. Kugler, Air Reduction Sales Co.

"90° Welded Nozzles, Piping—Calculations, Design and Fabrication," by F. C. Fantz, and W. G. Hooper, Midwest Piping & Supply Co., Inc.

"Extensions of Fusion Welding in Special Pipe and Pipe Fitting Applications," by E. Hall Taylor, Taylor Forge & Pipe Works.

"Engineering Fundamentals of Resistance Welding," by S. M. Humphrey, The Taylor Winfield Corp.

"High Speed Welding Assemblies," by E. W. Forkner, Federal Machine & Welder Co.

"Application and Use of Portable Spot Welders," by C. E. Heitman, Edward G. Budd Mfg. Co.

"Latest Developments in Resistance Welding," by R. T. Gillette, General Electric Co.

"Repairs to Castings and Other Steel Mill Parts," by S. S. Baumer, Bethlehem Steel Co.

"Welding in a Steel Mill," by R. P. Palmer, Wheeling Steel Corp.

"Flame Descaling and Flame Cleaning and Dehydrating," by J. G. Magrath, Air Reduction Sales Co.

"High Spots in Ship Welding," by E. D. Debes, Bethlehem Shipbuilding Corp.

"Designing Welded Frames for Continuity," by Bruce Johnston and E. H. Mount, Lehigh University.

"Design and Fabrication of Welded Structures," by C. E. Loos and F. H. Dill, American Bridge Co.

"Present-Day Practice in Structural Welding," by A. L. Wilson, Mississippi Valley Structural Steel Co.

"Maintenance of Way Welding," by C. E. Morgan, Chicago, Milwaukee, St. Paul & Pacific R.R.

"Automatic Welding in the Design and Construction of Railroad Rolling Stock," by F. C. Hasse, Oxweld Railroad Service Co.

"Production Panel Welding in the Manufacture of Freight and Passenger Cars," by J. W. Sheffer, American Car and Foundry Co.

"A Study of Welding Heat Effects," by W. A. Pearl, Armour Institute of Technology.

"Welding in the Manufacture of Valves for High Pressures and Temperatures," by W. F. Crawford and L. H. Carr, Edward Valve & Mfg. Co.

"Shrinkage of Steel Due to Welding," by Samuel T. Smetters, the Sanitary District of Chicago.

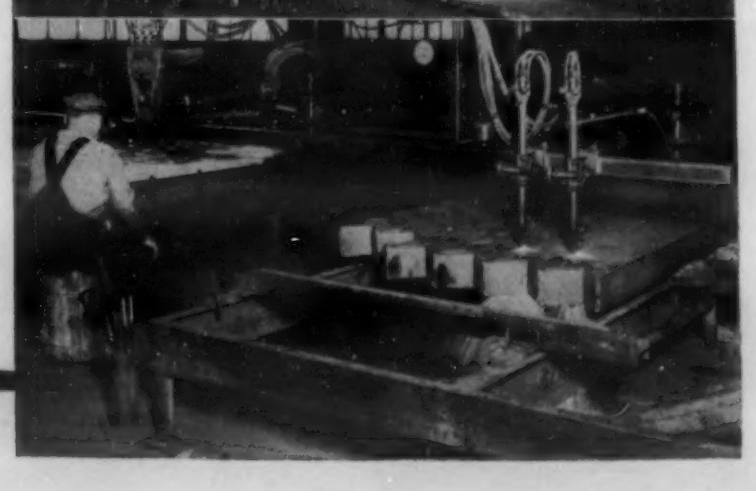
PRESIDENT

See Airco's



PRACTICAL DEMONSTRATIONS OF SOME OF THE MANY WAYS YOU CAN BENEFIT BY USING THE OXYACETYLENE FLAME

At the NATIONAL METAL EXPOSITION
Chicago, Oct. 23–27
Booth M-319

Automatic Production Welding

Featuring — the automatic welding of thin gauge, lead-coated steel oil floats; a practical demonstration of the value of Airco's Field Engineering Service which developed this operation.

Flame-Hardening

Featuring — Airco Flame Hardening Equipment, demonstrating the economy and the almost limitless application of "localized hardening" of metal parts.

Flame-Cleaning

Featuring — the equipment for surface conditioning of wrought iron and steel with Airco Flame Descaling and Flame Cleaning and Dehydrating.

Machine Gas Cutting

Featuring — the new Planagraph, an addition to the line of Airco Oxyacetylene Cutting Machines which fill the needs of industry for cutting steel in straight lines, arcs and circles, and irregular shapes with squared or beveled ends.

Arc Welding

Featuring—the complete line of Wilson Arc Welders, the machines that industry relies upon to make the arc behave. The New Wilson "Hornet" will be exhibited for the first time.

Pipe Welding

Featuring — Aircowelding, the fast, economical pipe welding process. The Airco Portable Pipe Cutting and Beveling Machine. The Airco Portable Weld Testing Machine.

Here's your chance to quickly, conveniently see the many industrial applications of the oxyacetylene process . . . to talk over your problems with Airco engineers . . . possibly to discover how to make your product better, faster, more economically. You'll find our representatives anxious to be of assistance to you — and qualified to give you expert advice.

DISTRICT OFFICES IN PRINCIPAL CITIES

Technical Program of the

Wire Association

DURING THE CONGRESS the Wire Association will hold its annual convention at which about 12 papers will be presented before both its ferrous and non-ferrous divisions. The sessions commence on Monday, Oct. 23 and extend through Thursday, Oct. 26 at the Congress Hotel.

The Mordica Memorial Lecture will be delivered Wednesday afternoon, Oct. 25, by Dr. S. A. Braley, Mellon Institute, Pittsburgh. That evening a smoker is scheduled. The tentative list of technical papers follows:

"Characteristics of Mild Steel Welding," by J. C. Joublanc, Technical Director, Harnischfeger Corp.

"Boulder Dam—The World's Outstanding Transmission Line," A Lecture with Motion Pictures, by Dr. Donald M. Simmons, Chief Engr., General Cable Corp.

"Submerged Heat by Submerged Combustion," by Walter S. See, Submerged Combustion Co. of America.

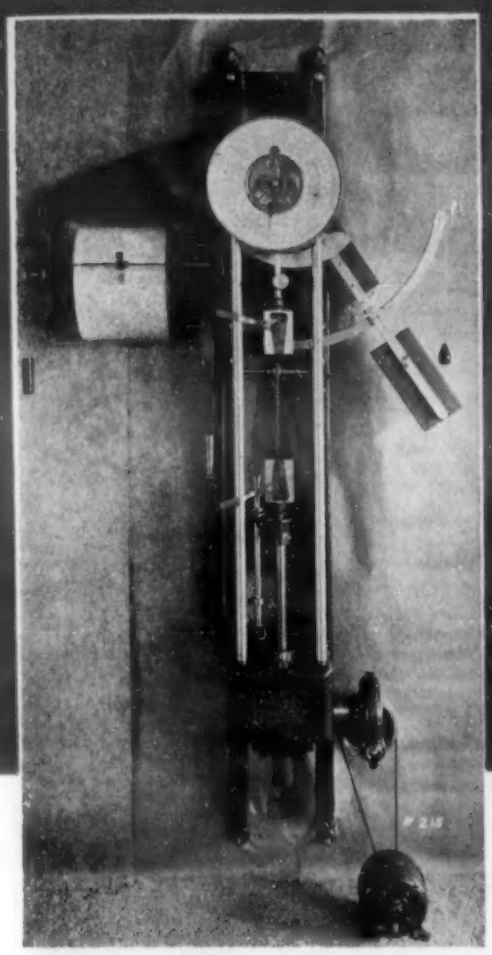
"Elasticity of Spring Wire," by George Nelson, L. A. Young, Spring & Wire Corp.

"Film Manufacture of Swedish Steel Rods," by Uddeholm Co. of America.

"Coating Wire with Paper Pulp," by J. S. Little, manufacturing engineer, Western Electric Co.

"The Brazing of Copper," by L. L. Wyman, research eng., General Electric Co.

"Atmospheric Annealing of Steel Wire," by Dr. A. A. Bates, manager chemical and metallurgical div., Westinghouse Electric & Mfg. Co.

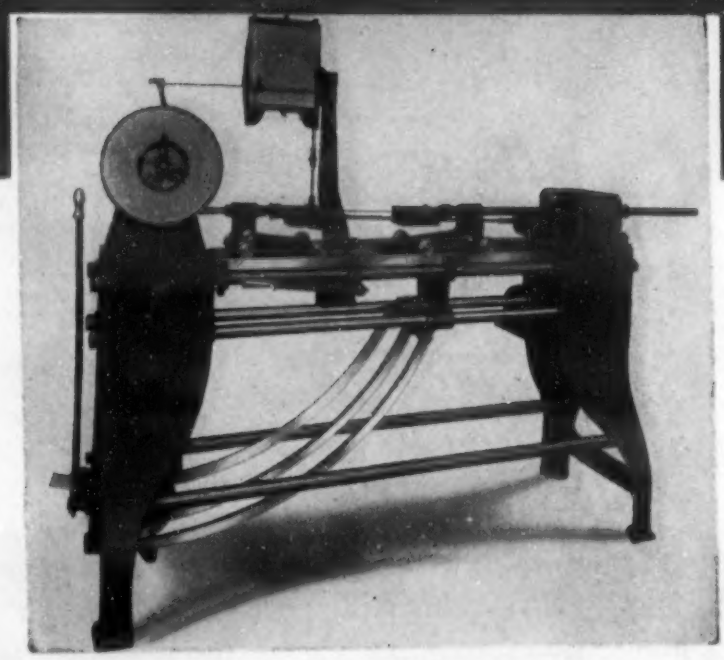


"Manufacture and Use of Stainless Steel Wire," by Stanley P. Watkins, manager, Rustless Iron & Steel Corp.

"Electrical Resistance Wires," by Dr. C. L. Mantell, technical director, Wilbur B. Driver Co.

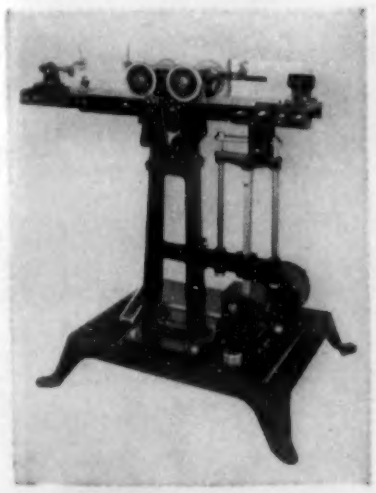
"Manufacture of Wire Solder," by Robert A. Gardiner, president, Gardiner Metal Co.

F. O. WESTPHAL
PRESIDENT



MODEL J-5

Standard for the tire wire industry, Model J-5, above, has cylindrical type recorder which magnifies stress-strain curve in ratios as high as 20 to 1. Clearly shows elastic limit, yield point, ultimate elongation and tensile strength. Capacities, 0-250 to 0-500 lbs. or 0-500 to 0-1000 lbs.



Model Q-4 *(right) is of heavier construction to adapt it for tests up to 2000 lbs. Like Model J-5, it measures load by the weighted pendulum principle, and strains specimen with positive gear drive. Can be furnished with cylindrical type recorder.*

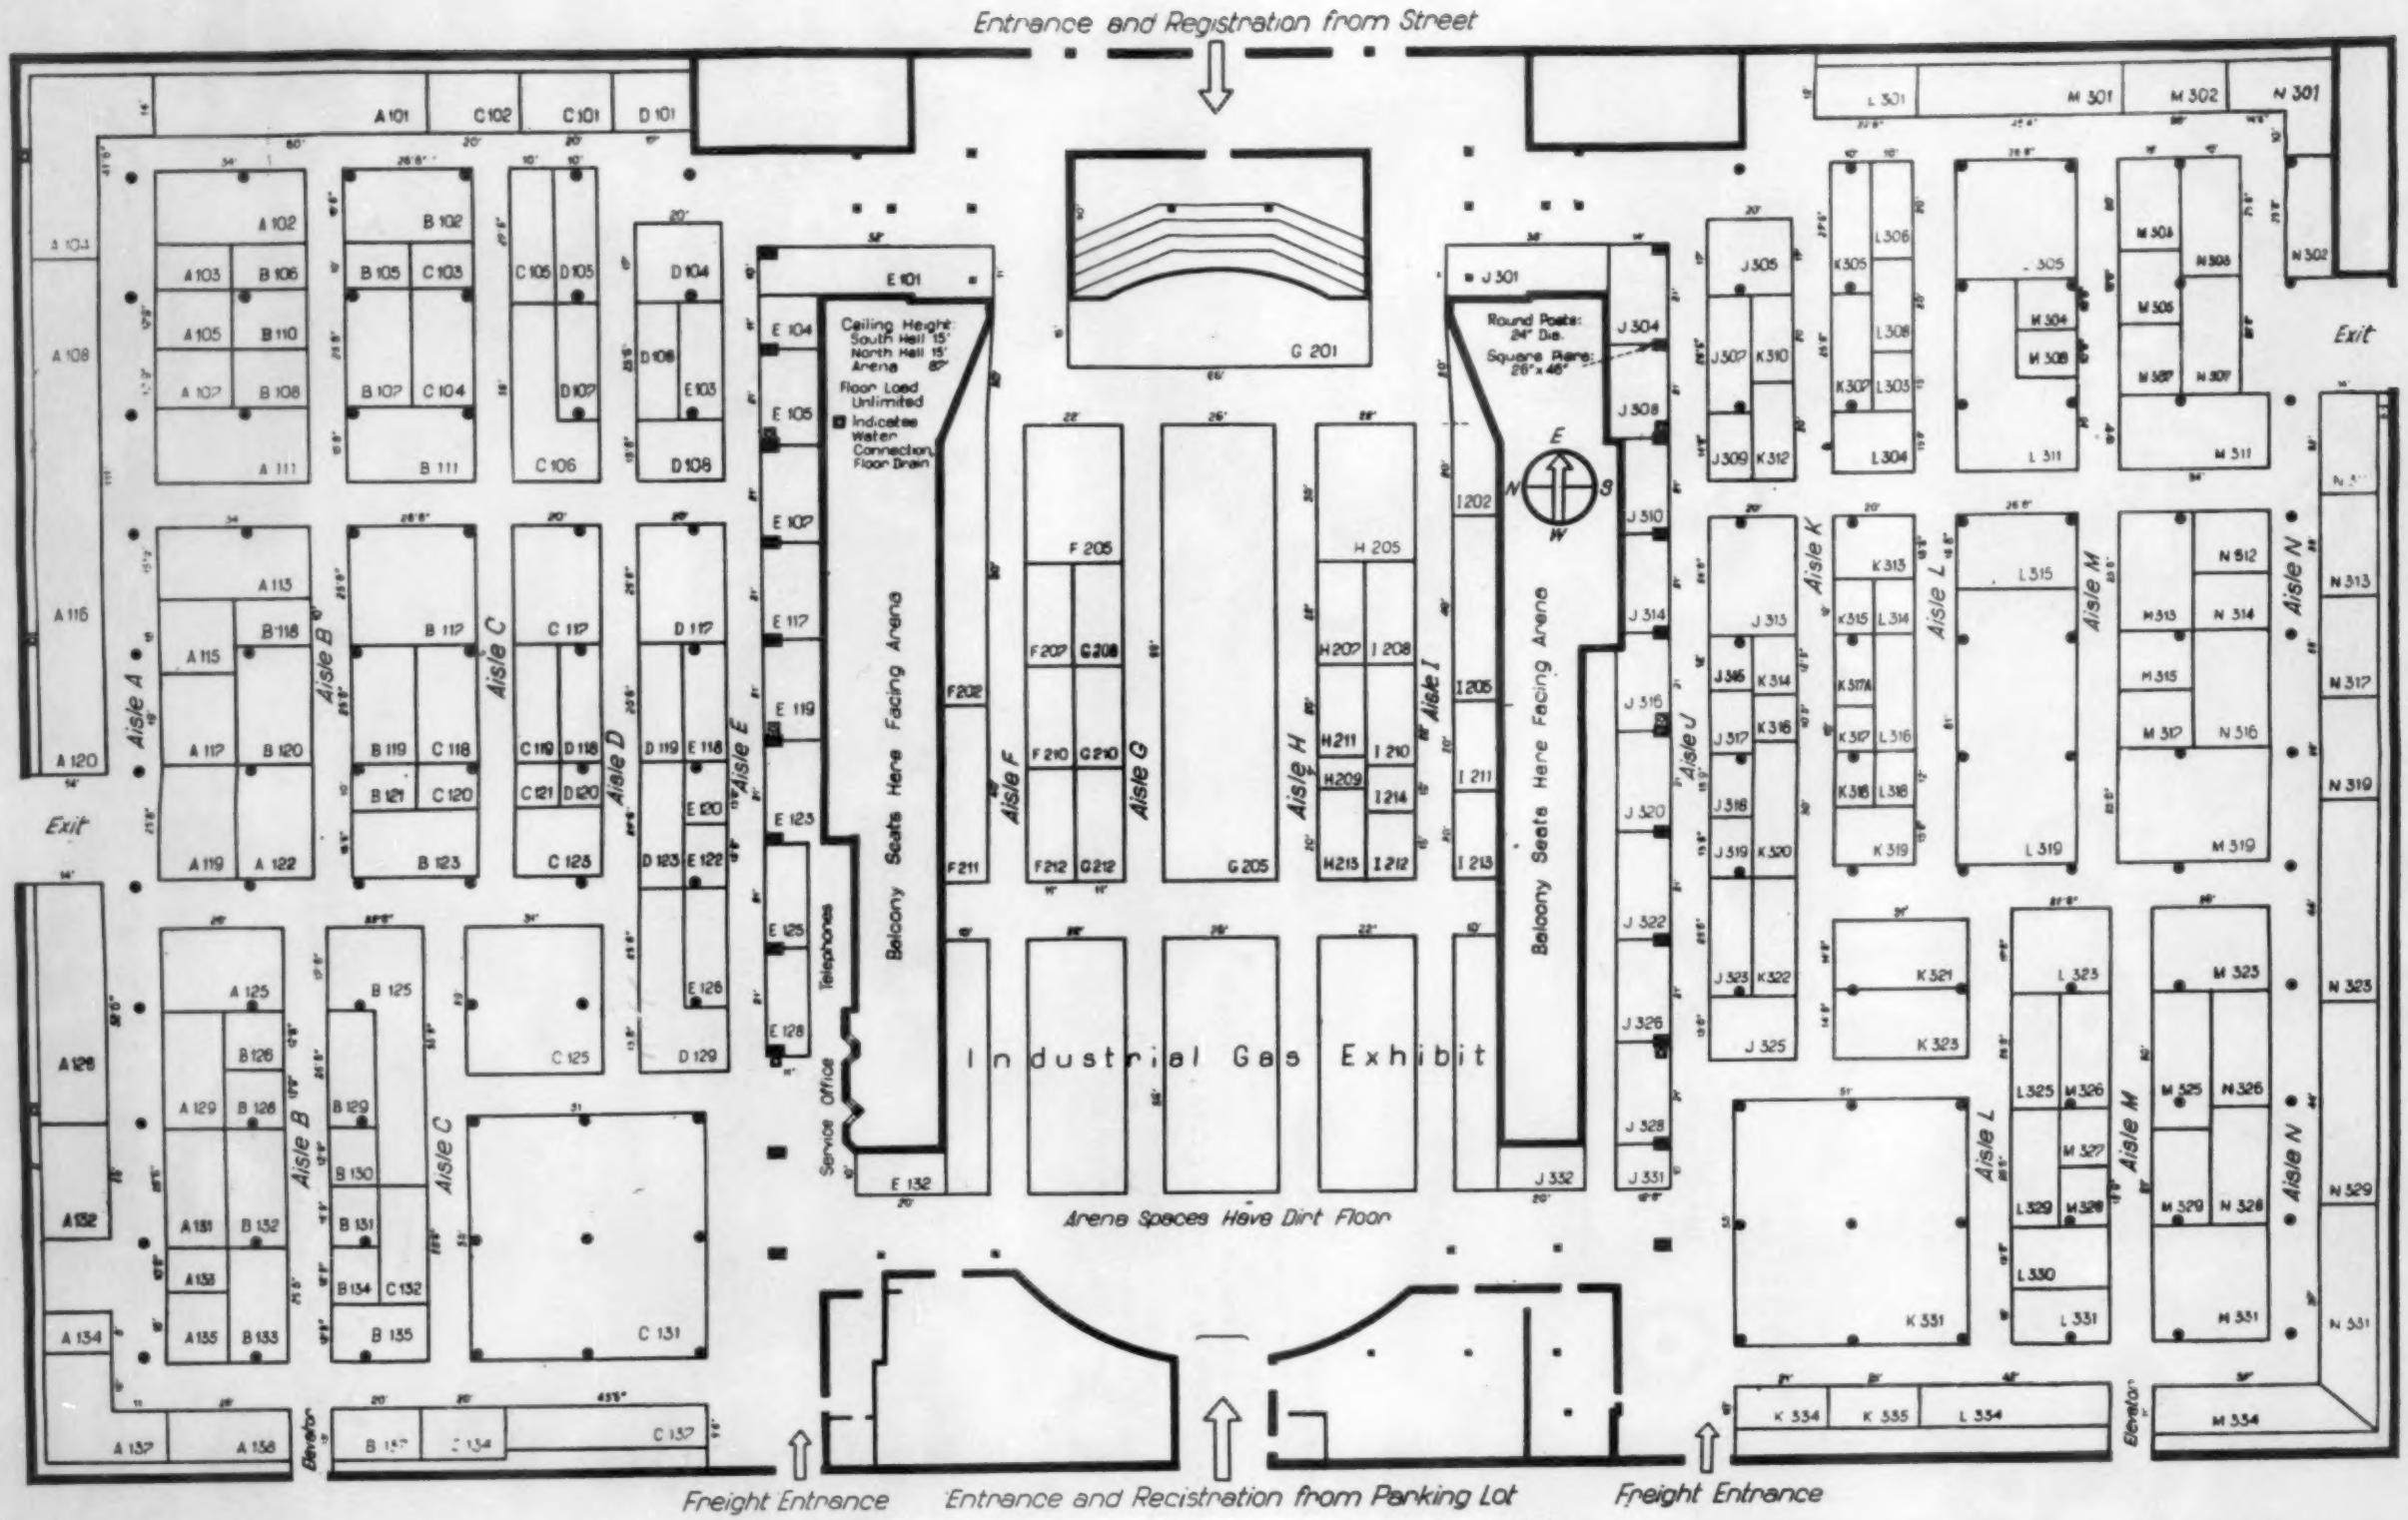
HORIZONTAL and VERTICAL WIRE TESTING MACHINES

SCOTT TESTERS

MODEL Q-4

MODEL 1-P-4

50 GRAMS TO ONE TON



Scott Testers offer the wire industry a range from ONE TON TO AS LOW AS 50 GR. for fine wire testing. Outstanding advantage of Scott Testers is the feature of defining the yield point by drawing the stress strain curve and showing ultimate elongation, tensile strength, and degree of hardness, at the same time.

In Model 1-P-4 (left) for fine wire testing up to 50 lbs., the adjustability in sample length on the incline plane machine allows wires of high or low stretch to be tested on a six inch wide chart.

SCOTT TESTERS

Scott engineers will gladly assist you in solving your testing problems:

Ten Years of Metallurgical Progress Reviewed

—1929 to 1939

Ten years ago—or more exactly, in July, 1929—the first issue of METALS AND ALLOYS, was published. Developments in the world of metals in that period have been exceedingly impressive. A brief but effective review of this progress was published in our July issue on the editorial page — "Time Marches On."

Partly because this year is the tenth anniversary of METALS AND ALLOYS, it has seemed appropriate to assemble and publish a series of reviews of developments in metallurgy and metallurgical engineering, covering the past ten years. Another reason is the desire to make more worth while the Preview Section of the magazine by substituting these reviews for material heretofore used, and available elsewhere.

We have another justification, if any be necessary, for such a series. It is our firm conviction that a 5-year or a 10-year review in the metal industry, or in any other, is far better and more representative of real progress than the oft-repeated annual reviews. Seldom is it the case that developments start and reach fruition in one year—their evolution and progress are usually from year to year, or over a period of years.

To present these ten-year developments, we have asked each member of our Editorial Advisory Board and of the staff to contribute. Each one of the Board is a specialist in his field and his utterances are authoritative. We have been highly fortunate in their cooperation. Our editorial director has dealt with one of several themes with which he is so familiar. Because there were a number of important fields which unfortunately, are not represented on our Board, we have asked certain leaders in these fields to contribute—they have given valuable assistance.

Manifestly all important subjects could not be embraced in this assemblage, due partly to space limitations. It has fallen to the lot of the editor to attempt to cover at least part of these as his share of the contributions. The assistant editor discusses the powdered metals, a subject with which he is keeping in close touch.

There are some 30 or more reviews in this rather impressive aggregation. We recommend them to the perusal of our readers and take some pride in them. The splendid cooperation of each contributor is gratefully acknowledged.—E. F. C.

Die Castings

by Harvey A. Anderson

General recognition of the unique suitability of die castings for economic application in a wide diversity of products has resulted in quadrupling the volume of production during the last ten years. With the solid background of major consumption in automobiles, die cast parts have been adopted in other large unit production lines, such as telephone apparatus, household appliances, toys, radios, and typewriters, where no other method of manufacture can produce so cheaply an intricately shaped part with high grade surfaces and closely controlled dimensions.

Zinc Alloys

The applications of die castings range from strong massive radiator grilles weighing 27 lbs. each to small intricate zipper teeth weighing a fraction of a gram each. The available materials include soft corrosion-resistant tin and lead alloys, ultra-light easily machinable magnesium alloys, light corrosion-resistant aluminum alloys, the generally popular zinc alloys, and 100,000 lbs. per sq. in.-strong brass alloys. The American Bureau of Metal Statistics reports an average production of 60,000 tons of zinc base die castings annually during the last five years and an all time peak production of 88,000 tons in 1937.

The rapid growth in the production of quality die castings may be said to date from the first commercial availability of 99.99+ per cent pure zinc, which Gillett calls our first low cost super-pure metal. Other companies have followed the lead of the first "4 nines" zinc producer and one large supplier has made numerous valuable contributions to our technical knowledge of zinc alloys. The A.S.T.M. has provided an excellent forum in its die casting committee for critical appraisal of new alloys by both producers and consumers. The resulting specifications incorporate requirements based on committee sponsored corrosion tests involving hundreds of thousands of specimens.

Dependable information has been disseminated regarding the detrimental effect of contamination of zinc alloy die cast parts by thousandths of a per cent of lead, cadmium, and tin. This necessitates routine spectrographic control of alloy purity. Radiographic control of casting soundness, and pyrometric control of alloy and die temperatures are other refinements which are used in the production of low cost die castings. As a result smooth dense zinc base die castings of intricate shape and accurate dimensions are now produced regularly. These exhibit high tensile and impact strength and elongation even after ten days exposure to 95 deg. C. steam. This test, equivalent to years of exposure in the worst seacoast or industrial atmospheres, results in dimensional changes in high quality die cast parts of less than 0.05 per cent. Aluminum, magnesium and lead alloy producers have also made noteworthy contributions to the progress in alloy developments.

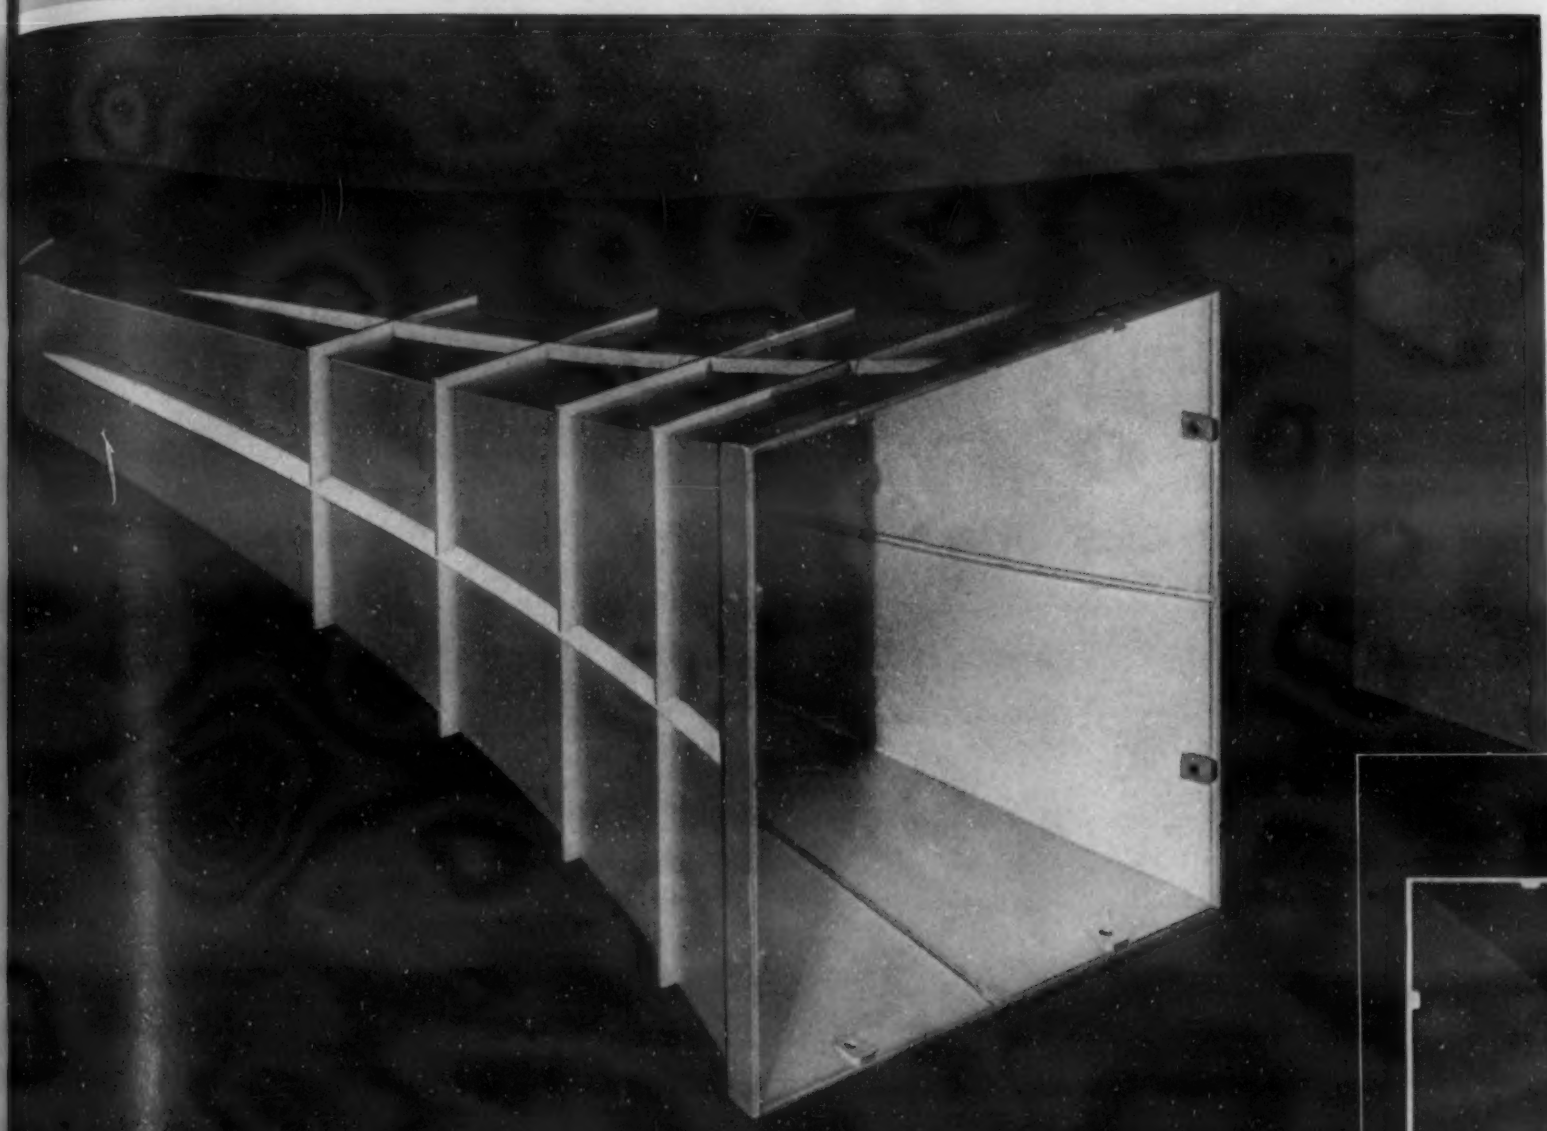
Die Casting Machines

The development of improved die casting alloys has been paralleled by equally noteworthy improvements in die design, die casting machines and technique, including higher metal pressures and vacuum casting. The ingenuity of the die designer and the machine builder has stimulated the development of many new products. Electroplated and organic finishes have assisted materially in widening the market for die castings.

One field of development which has challenged metallurgical ability has been the production of better die steels. The demand for new low cost dies, such as sound cast dies with integral cooling channels and permanent high quality cavity surfaces, as well as for longer life steel for brass die casting dies, forecasts still further improvements along the line of die construction. New die casting machines show a tendency to more rigid construction, with higher pressure die closures and vacuum chambers to avoid air entrapment and consequent porosity of castings.

New Alloys and Applications

The 1939 automobile models utilized die castings for new uses such as headlamp bezels and nameplates, and this tendency to further replace stampings by die castings bids fair to continue in the future. Buick's new direction signal employs 13 die castings per unit which are assembled with molded transparent plastic inserts. The modern tough high strength zinc alloys can be die cast in straight sections with thin walls and subsequently formed to the desired shape.



A new aluminum base alloy with 10 per cent magnesium has recently come into some prominence. A recent article in *Aero Digest* reports the use of a single die casting to replace an assembly of several parts including stampings, welded tubing, sand castings and screw machine products, with improved rigidity as well as cost savings.

The use of magnesium base alloy die castings may be expected to increase greatly in the future with quantity airplane production, and other uses made possible by the corrosion protection of the new organic coatings. Magnesium alloyed with aluminum and silver offers attractive possibilities. Brass die castings are also being used to some extent in aircraft as well as in motion picture camera and projection assemblies. The prospects for die casting making greater contributions to the economic progress of the future appear excellent.

ZINC ALLOY DIE CASTINGS

ACCURACY

—In A 20" Span

This is a loud speaker horn for a public address system. It is produced as a ZINC Alloy Die Casting for the reasons outlined below, among others.

1. ACCURACY—It is absolutely essential that this part be accurately shaped—and smooth surfaced—to form a perfect acoustical path. As a ZINC Alloy Die Casting, the important dimensions are held within plus or minus 0.002 in.—0.030 in. limit for the overall 20 in. length.

2. RIGIDITY—The acoustical factor also demands that the horn be of sufficient stiffness to maintain its shape in service. With a section thickness of approximately 0.065 in., the die casting easily meets this requirement—although subjected to considerable abuse. (Note the use of strengthening ribs).

3. LOW RESONANCE—The choice of material was extremely important in this application. Properly designed ZINC Alloy Die Castings have a quality of low resonance which makes them adaptable for use in sound carrying equipment.

4. ECONOMY—The only machining required on this part is the drilling of some small holes. And, being of one-piece construction, assembly costs are eliminated.

This application, like most others, has rather unusual requirements. But the ease with which ZINC Alloy Die Castings are solving production problems—in many industries—makes it imperative that you be well versed in this modern metal and method of fabrication. Consult any commercial die caster—or write to this Company for additional information.

THE NEW JERSEY ZINC COMPANY

The Research was done, the Alloys were developed, and most Die Castings are made with

HORSE HEAD SPECIAL (99.99+% UNIFORM QUALITY) ZINC

Electroplating

by William Blum

Although 10 years sometimes seems like a long period, very few major developments in any industry come into extensive use within a decade. Consequently any decennial review must include activities that were initiated or anticipated before the beginning of the period, and also those which are now incipient and may or may not mature. In spite of these limitations, I will try to survey briefly, and without specific literature references, the recent developments in the plating field.

Direction of Changes

Even more important than specific improvements, some of which may be sporadic, is the direction of the changes, as this is likely to determine future activities. The electroplating industry has just passed into its third stage. The first stage was represented by the numerous job shops, usually small, and with little opportunity for technical control. The second stage involved large, controlled-production plating units, especially the automatic conveyor installations for the automobile industry that came into use from 1920 to 1930. (The large job shops, better known as "contract platers," belong in this class rather than in the first.) Each of these two classes has a definite place in industry, and they will be supplemented and not superseded by the third class.

The latter may be defined as "preplating," that is, the plating on a very large scale of wires, strips and sheets of metal prior to their fabrication into finished products. The most successful of such operations is the zinc plating of wire at very high current densities, in the "Bethanizing" process. The greater purity and flexibility of the plated zinc coatings make them superior to hot-dipped coatings for certain purposes. Experiments in progress on zinc plating of strips and sheets are encouraging. In these and similar processes, the new methods must be sufficiently better or cheaper than existing procedures to warrant the scrapping of present expensive installations, or else the gradual supplanting of the old process as its equipment becomes obsolete.

Electrolytic Tin Plating

The latter situation partly accounts for the relatively small proportion of tin-plate that is coated electrolytically, even though several successful tin plating processes have been developed and installed. Another problem is to adapt the electro-tin-plate to existing methods of can fabrication, especially the soldering. One advantage of the electroplating process (for both zinc and tin) is that the thickness can be controlled so as to meet any particular requirements more closely and uniformly than can be done conveniently by hot-dipping.

It is not likely that preplating will replace much of the high quality plating of finished articles. The presence of cut, uncoated edges is usually objectionable, but less so with zinc than with tin, nickel, or other metals that do not furnish protection to exposed steel. It is probable that plated sheets will replace hot-dipped sheets, or will lead to new uses of preplated steel.

Electroforming of copper sheets, and of more complicated shapes, including parts of musical instruments, has made substantial progress, not so much through new procedures as through very close control of operating conditions, especially the exclusion of suspended particles from the baths.

The use of heavy deposits, especially of nickel and chromium, for building up worn or under-sized parts is much more extensive in England than in this country, though interest here is now increasing. The difference in practice may be caused in part by the relative costs of labor and material in the two countries.

The use of chromium for wear resistance has shown a steady increase in varied fields of service.

Increase in Research

The last decade has been marked by an increase in researches on electroplating, especially in England and America. These have covered many phases of (a) principles of electrodeposition, (b) new methods of plating, including several new or rare metals, and (c) the specification and testing of deposits (including dropping tests and non-destructive magnetic methods). In certain respects the tests and specifications are most important, because they assist the electroplater to meet definite conditions of service and thus to compete successfully with other materials such as corrosion-resistant alloys, and with plastics, or with other methods of protection, including paint and enamel. Without such ability, the plating industry would soon decrease in importance.

The rapid development of bright nickel and bright zinc plating illustrates the value of intensive research on plating, and also the need for more exhaustive studies on principles of electrodeposition. Until there is a better understanding of the structure of deposits, of its relation to the composition of the baths, and to the polarization and gas-overvoltage, and of the mechanism of addition agents, much of the progress, however real and valuable, rests on a "cook-book" basis. Large industries and technical societies may well encourage and support more fundamental research on plating.

The preceding comments may be summarized in the conviction that the electrodeposition of metals will play a more important part in the future than in the past. Such progress will depend upon cordial and intelligent cooperation of electroplaters, chemists, metallurgists, engineers, and executives. Plating is no longer simply a skilled trade.

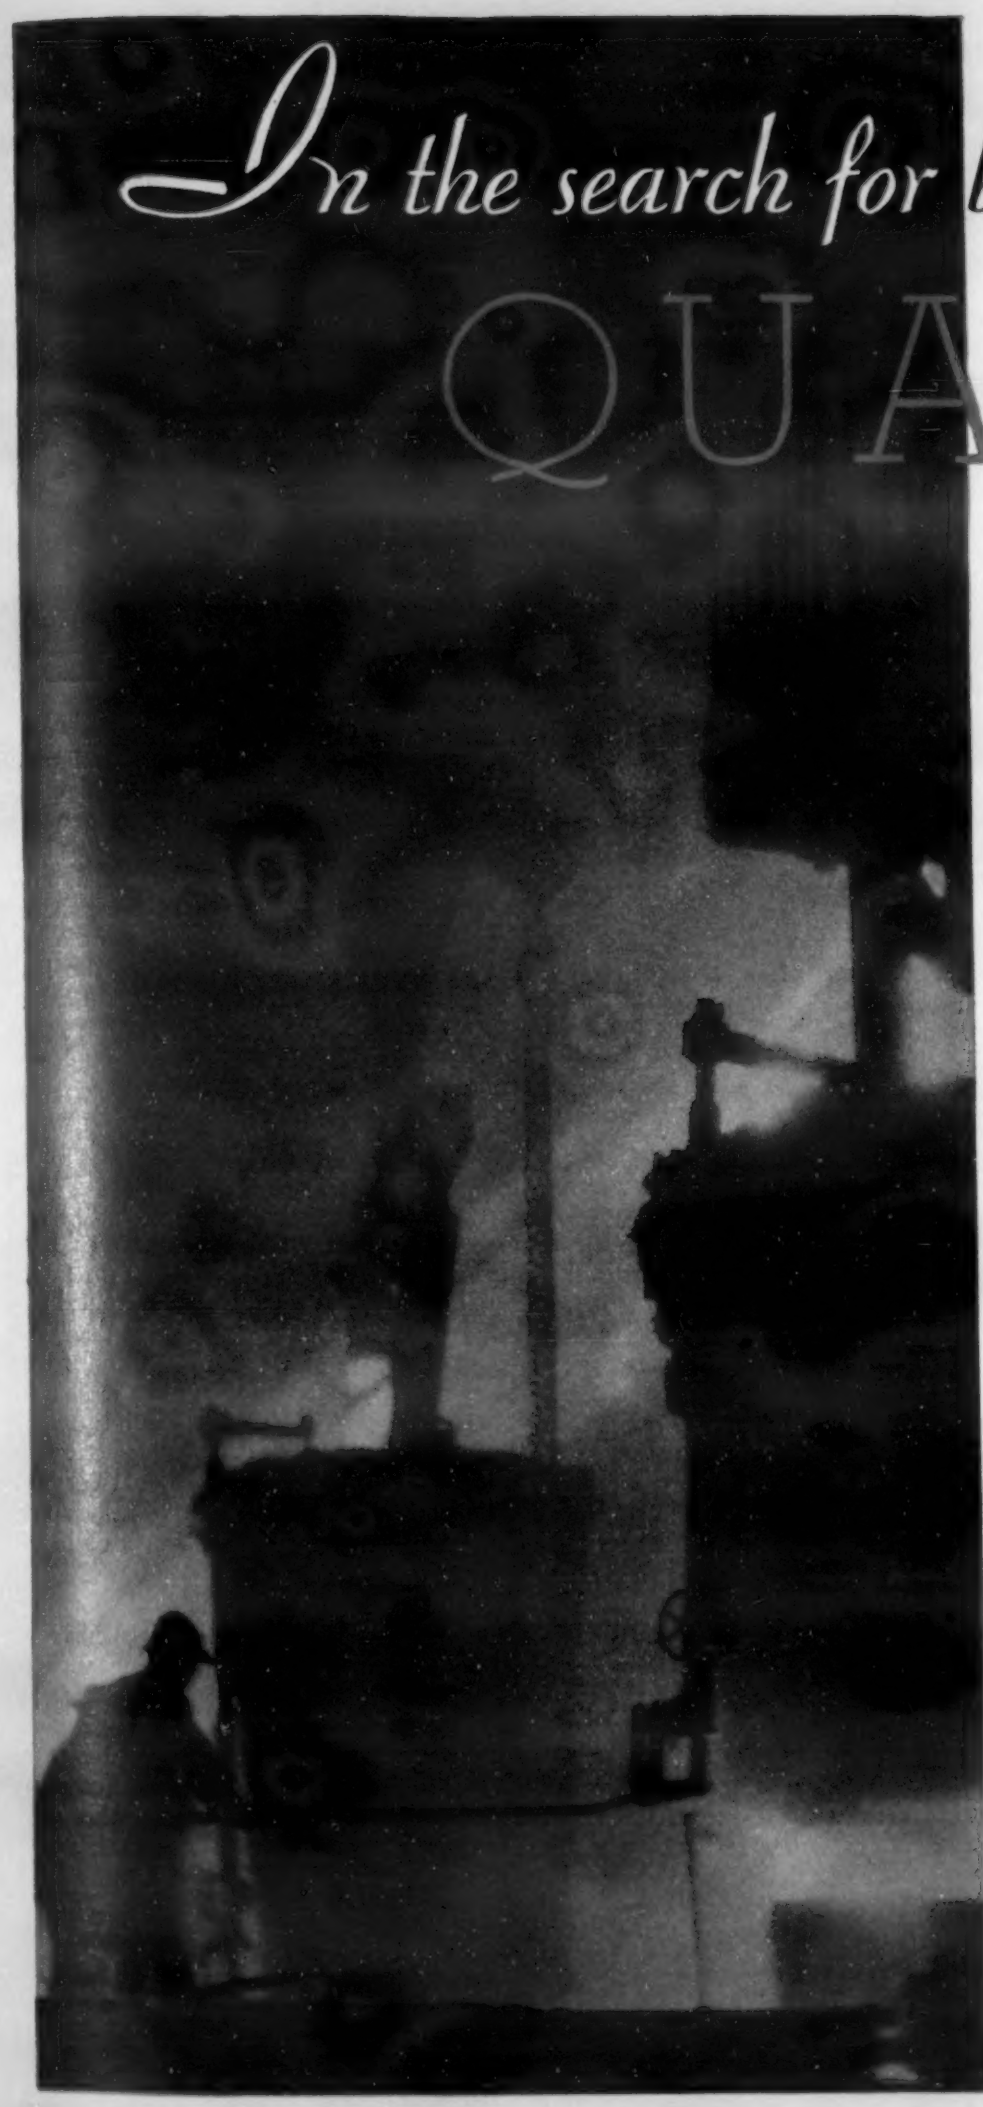
Metals and Alloys in the Automotive Industry

by A. L. Boegehold

Improvements in automotive materials will be discussed under the five principal groups: Malleable iron, cast steel, cast iron, wrought steel, and bearing metals.

Malleable Iron

Development has occurred both in the annealing process and in modification of structure and hardness. The principles for drastically reducing annealing time were available more than 10 years ago but only in the last decade have these principles been utilized for shortening annealing cycles from over 100 to 30 hrs. for the regular variety of malleable iron. Irons with higher silicon and lower carbon are being annealed in 15 hrs. or less.



The use of incompletely annealed or reheat-treated malleable iron, covered by the general term "pearlitic malleable iron," has expanded. Rocker arms, camshafts, and pistons, are made from this material. Its use for pistons has been confined to two-cycle Diesel engines. Camshafts made from malleable iron have cams surface hardened by the high frequency induction method, itself a new development.

Cast Steel

Cast steel, which had practically no applications in automobiles 10 years ago, has been developed by one prominent automobile manufacturer. The development of a high carbon alloy cast steel having better casting properties than those previously known has helped its use for crankshafts, brake drums, and pistons. Transmission and rear axle gears have been made by centrifugally casting in a metal mold, a composition similar to that used for forgings.

Cast Iron

New alloys having special properties including high strength and wear resistance have led to special uses for cast iron. Of special alloys for camshafts, one variety contains low silicon and high

In the search for better and better QUALITY

THROUGHOUT the history of American metallurgy runs the tireless search for better and better quality—cleaner, more homogeneous metals,—finer finished products. And the Titanium Alloy Manufacturing Company has been—still is!—a pioneer in this search.

Producing over 30 years ago, the first commercial Titanium Alloy for use in molten steel, TAMCO since then has developed TAM Alloys for practically every class of steel, as well as alloys for other metals.

The two TAM Ferro Carbon Alloys—TAM *Original* F.C.T and TAM Medium Carbon F.C.T.—are outstanding Titanium deoxidizers helping to produce superior steels, from the highest carbon down to the lowest carbon made! Supporting these leaders is a comprehensive list of TAM Alloys and Products for all needs of the practical metallurgist.

TAM 40% *Low Carbon* Ferro Titanium, TAM Foundry Ferro Titanium (for cast iron), TAM Webbite (for aluminum), TAM Cupro-Titanium (for copper), TAM Metallic Titanium, and TAM Metallic Zirconium. Also TAM Foundry Zircon Sand and TAM Zirconite "A", both super-refractory mold and core materials; and in addition to these many other refractories and cements.

A TAM Engineer is always ready and willing to assist your plant with accurate, up-to-the-minute information.

copper controlled so that the point of the cam solidifies white, thus making further treatment of the cams unnecessary. Another alloy for camshafts gives good results when the cam points are hardened by heating with an oxyacetylene flame. Cylinder liners for truck and bus engines, possessing hardness over 500 Brinell after heat treatment, have been adopted. The high hardness has reduced wear to a small fraction of that experienced previously.

Developments in brake drums first led to substitution of higher carbon steel pressed drums which were then displaced by cast iron. High strength cast iron was used until it was found that a good grade of cylinder iron gave satisfactory results. For reducing the cost of cast iron drums a composite drum was developed with steel back and cast iron rim. Two varieties of this type of drum are used. One with the cast iron rim sheathed with and bonded to steel, this rim in turn being riveted to the steel back; the other variety having a steel back inserted in the mold and cast iron flowed around the dove tailed edge uniting the back and rim. Some alloy cast iron is used for crankshafts in other than automobile engines such as in agricultural vehicles.

Steel

The high frequency surface hardening process referred to above under malleable iron is an important recent development. This is used for hardening crankshaft journals, rear axle shaft bearing races, and other similar applications. A steel containing 0.25 per cent chromium and otherwise similar to S.A.E. 1045 steel was developed for use with the surface hardening treatment. Automobile ring gears and pinions have had steady development beginning with substituting S.A.E. 4615 and S.A.E. 4815 steels for S.A.E. 2315, 2515, and other steels, and adoption of box quenching ring gears and pinions without subsequent reheating because of the decided decrease in distortion. With increased knowledge concerning resistance of various alloy carburizing steels to cyclic stress, less expensive steels for rear axle gears including 4100, 3100 and 1300 series steels carburized and box quenched have been used.

A new composition to appear for automobile parts, being used first as a spring steel, was one containing 0.20 to 0.25 per cent molybdenum and possessing a very fine grain size.

The steady increase in the severity of conditions imposed upon exhaust valves has lead to abandonment of the old silchrome composition in favor of austenitic steel containing 22 per cent chromium and 10 per cent nickel for the head welded to a pearlitic steel stem. The latest development is a non-austenitic steel containing 24 per cent chromium, 5 per cent nickel and 3 per cent molybdenum.

For hardening steel without quenching there is the process of simultaneous gas carburizing and nitriding producing an extremely hard surface with greater load carrying capacity. The nitriding process has benefited by introduction of a 4 to 6 per cent chromium-molybdenum steel having resistance to tempering which permits nitriding at usual nitriding temperature without reducing the core hardness below 40 Rockwell C.

For obtaining steel quality, the use of hardenability tests has been consistently increasing and probably will eventually replace specifying steel by grain size. The hardenability test characterized by quenching the end of a 1-in. round specimen is meeting with considerable favor and appears to meet the requirements for a universal hardenability test.

The principal developments in machining are the use of re-sulphurized steel and leaded steel. The re-sulphurizing treatment is applied not only to low carbon screw stocks but also to higher carbon steel like 1045 for use in crankshafts. Lead additions are made also to all varieties of steel. New tool materials are the molybdenum high-speed steels with or without tungsten.

Bearing Metals

The demand for better bearing materials has resulted in steel backed copper-lead bearings, cadmium-silver bearings, cadmium-nickel bearings and the resurrection of high lead-babbitt used many years ago but now bonded to a steel back. Copper-lead bearings and the cadmium bearings are subject to corrosion when lubricating oil attains excessive temperatures so that additional development in bearing metals is necessary and this development is at present going on and the near future will see improved bearing materials to meet the more drastic present day requirements.

Powdered Iron

A development which is quite recent is the manufacture of various parts from powdered iron. With the aid of Swedish powdered iron a number of automobile parts are already being made in production and as soon as cheaper powdered iron is available, which can now be foreseen, the number of automobile parts made by this process will greatly be increased.

Metals and Alloys in the Electrical Industry

by P. H. Brace

Special alloys have played important parts in electro-technology for many years. Some alloys owe their existence to electrical production methods and these have in turn strongly influenced electrical progress because they enabled new things to be done by electrical means. The electrical industry has frequently found it necessary to take the initiative in the development and initial production of new alloys to serve its particular needs and has been quick to make use of pertinent new things from the laboratories of the metallurgical industries. During the past 10 years the latter have been increasingly alive to the desires of the electrical men.

The General Picture

New combinations of properties are persistently sought, now with emphasis on this or that magnetic characteristic, again with resistivity or thermal expansion in mind. Stability at elevated temperatures, corrosion resistance, mechanical properties at various temperatures as well as availability, cost and ease of manipulation are among the factors which the electro-technologist seeks to adjust and combine in his never-ending efforts to improve the effectiveness of the multitude of electrical devices that surround us.

The interesting nature of some of the more recent alloy developments and the urge for new things has attracted attention from the physicists who have been giving special attention to the fundamental problems of the metallic state. New and useful concepts have been developed concerning the arrangements and interaction of metal atoms and the practical consequences. Educational institutions and metallurgical societies have sought to bring together the pure scientist and the practising metallurgist to the benefit of both.

Magnetic Materials

Now to the metals themselves. Magnetic materials have a dominant place in the electrical world and a surprising variety of new magnetic materials have come into use during the decade. In the permanent magnet field the number has risen from four or five to 20. Outstanding are the Ni-Al-Fe alloys discovered by the Japanese, Mishima, and elaborated by others. Alloys of this type possess much higher magnetic performance than the customary permanent magnet alloys, together with a moderate materials cost.

Other alloys of somewhat similar characteristics and substantially higher performance contain tungsten, titanium and cobalt in addition to nickel, aluminum and iron. Fe-Mo-Co and Cu-Ni-Co alloys with useful magnetic characteristics and a useful degree of workability have been developed and used to some extent. Most remarkable of all is a platinum-cobalt alloy containing approximately 77 per cent Pt which has a coercive force 40 times and a performance factor per unit volume 12 times as great as the 3 per cent chromium magnet steel commonly used for permanent magnets. These properties are so remarkable that this material will undoubtedly find uses despite its high cost.

These new materials have enormously widened the field of action of designers of apparatus employing permanent magnets.

In the Telephone Industry

In the telephone industry there has been much activity on the development and application of low hysteresis-high permeability

MASTER ALLOYS

FOR

POWDER METALLURGY

The synthetic alloys produced by mixing, pressing, and sintering pure powdered metals, are already here and will solve a number of production problems. Yet the introduction of some alloying elements such as chromium, titanium, zirconium, etc. by methods of powder metallurgy, presents similar difficulties as in fusion metallurgy. In both cases this difficulty is solved by the use of master alloys instead of pure metals.

Metal Hydrides, Inc. offers a number of powdered master alloys of almost any desirable composition. They can be added to the powdered mixtures of base metals and handled by standard methods of powder metallurgy without danger of loss of expensive alloying elements.

"HYDRIMET" POWDERED MASTER ALLOYS

Nickel-Chromium	Nickel-Thorium
Nickel-Uranium	Copper-Titanium
Nickel-Titanium	Copper-Zirconium
Nickel-Zirconium	Cobalt-Chromium

Factory—Beverley, Mass. **P. O. Box 816 Clifton, Mass.**

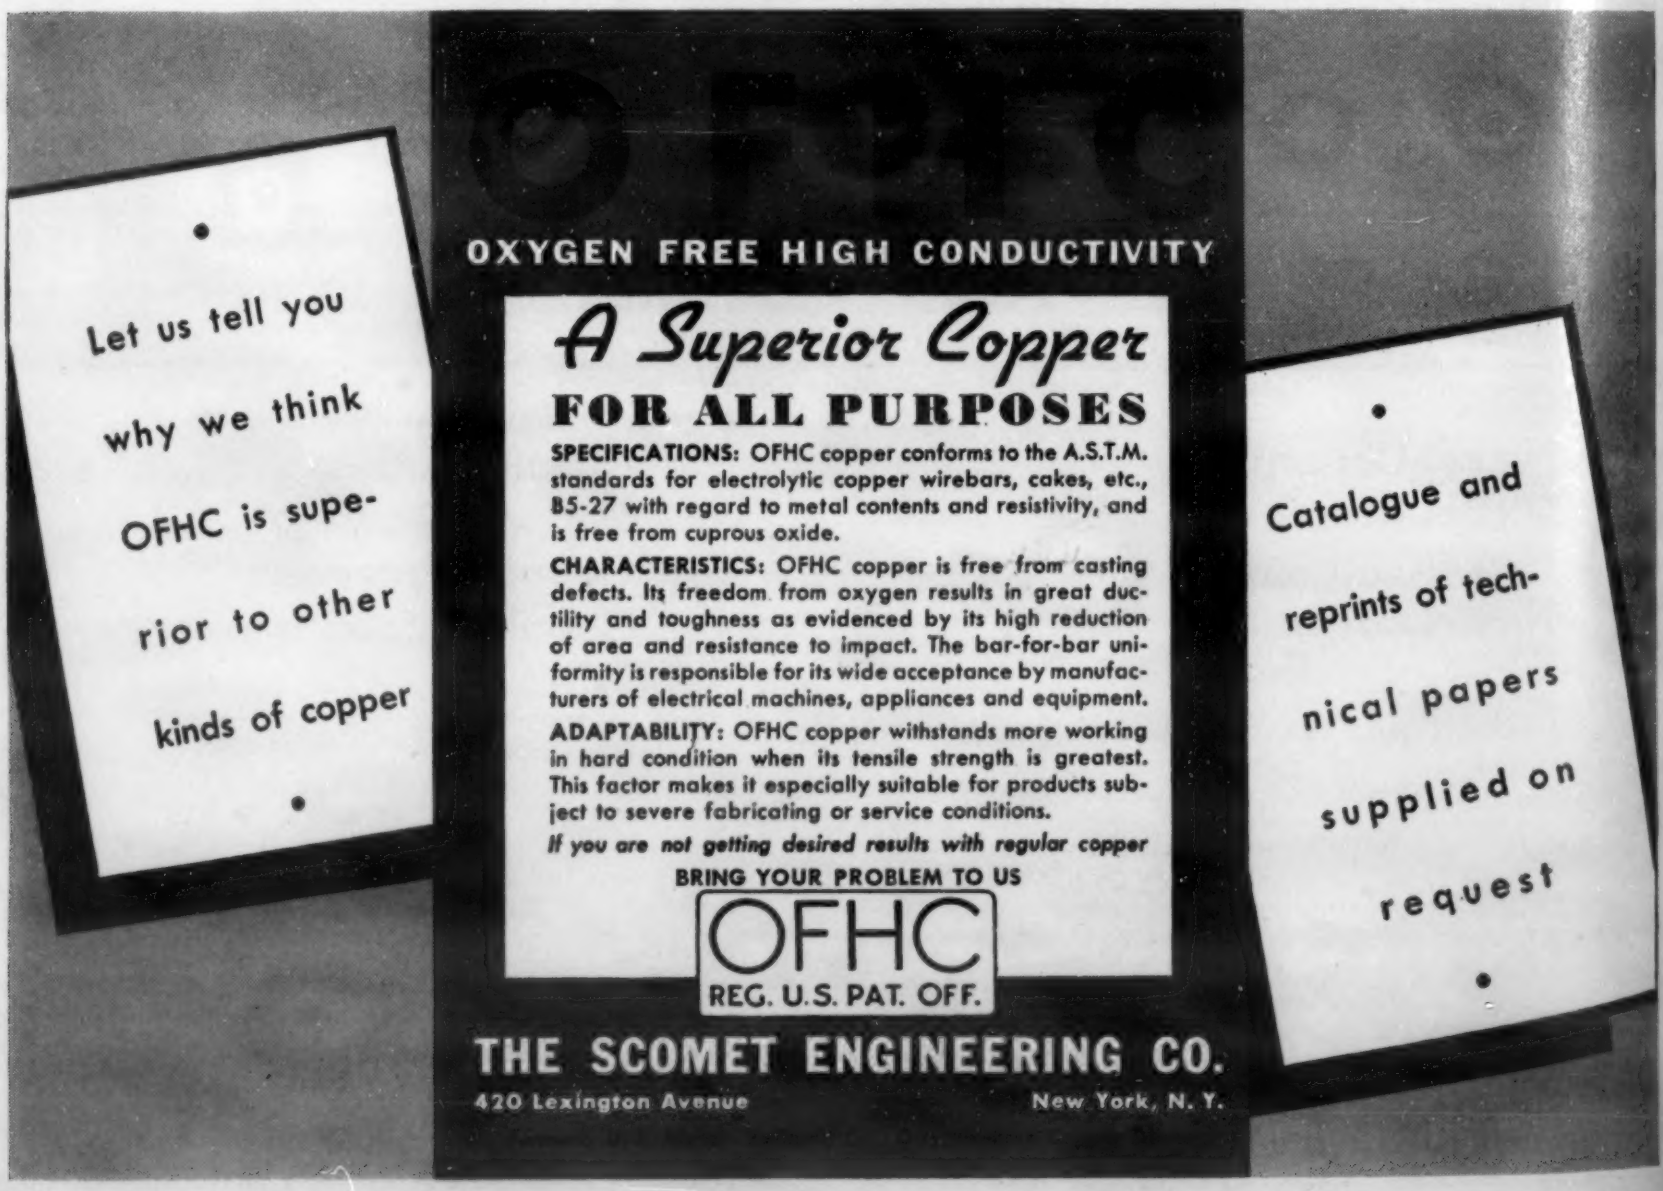
alloys for various special purposes such as cores for loading and filter coils on long telephone lines and for magnetic loading of submarine cables. These alloys are based on Ni-Fe and Ni-Fe-Co with various additions among which are molybdenum, chromium and vanadium which act to control resistivity, permeability and working characteristics. New methods for preparing pure alloys have been developed and important discoveries made as to the effects of heat treatment and cold work on crystal orientation and of the relation of magnetic performance to structure. In the laboratory for single crystals, permeabilities approaching 1.5 million have been reported.

These new materials and processes have had far reaching effects in reducing size and cost and improving performance of equipment for communication by land, sea and air. The spread remaining between the performance attained with commercial alloys and that which could be realized with some of those still in the laboratory warrants the expectation of considerable further progress during the next 10 years.

Electrical Conductors

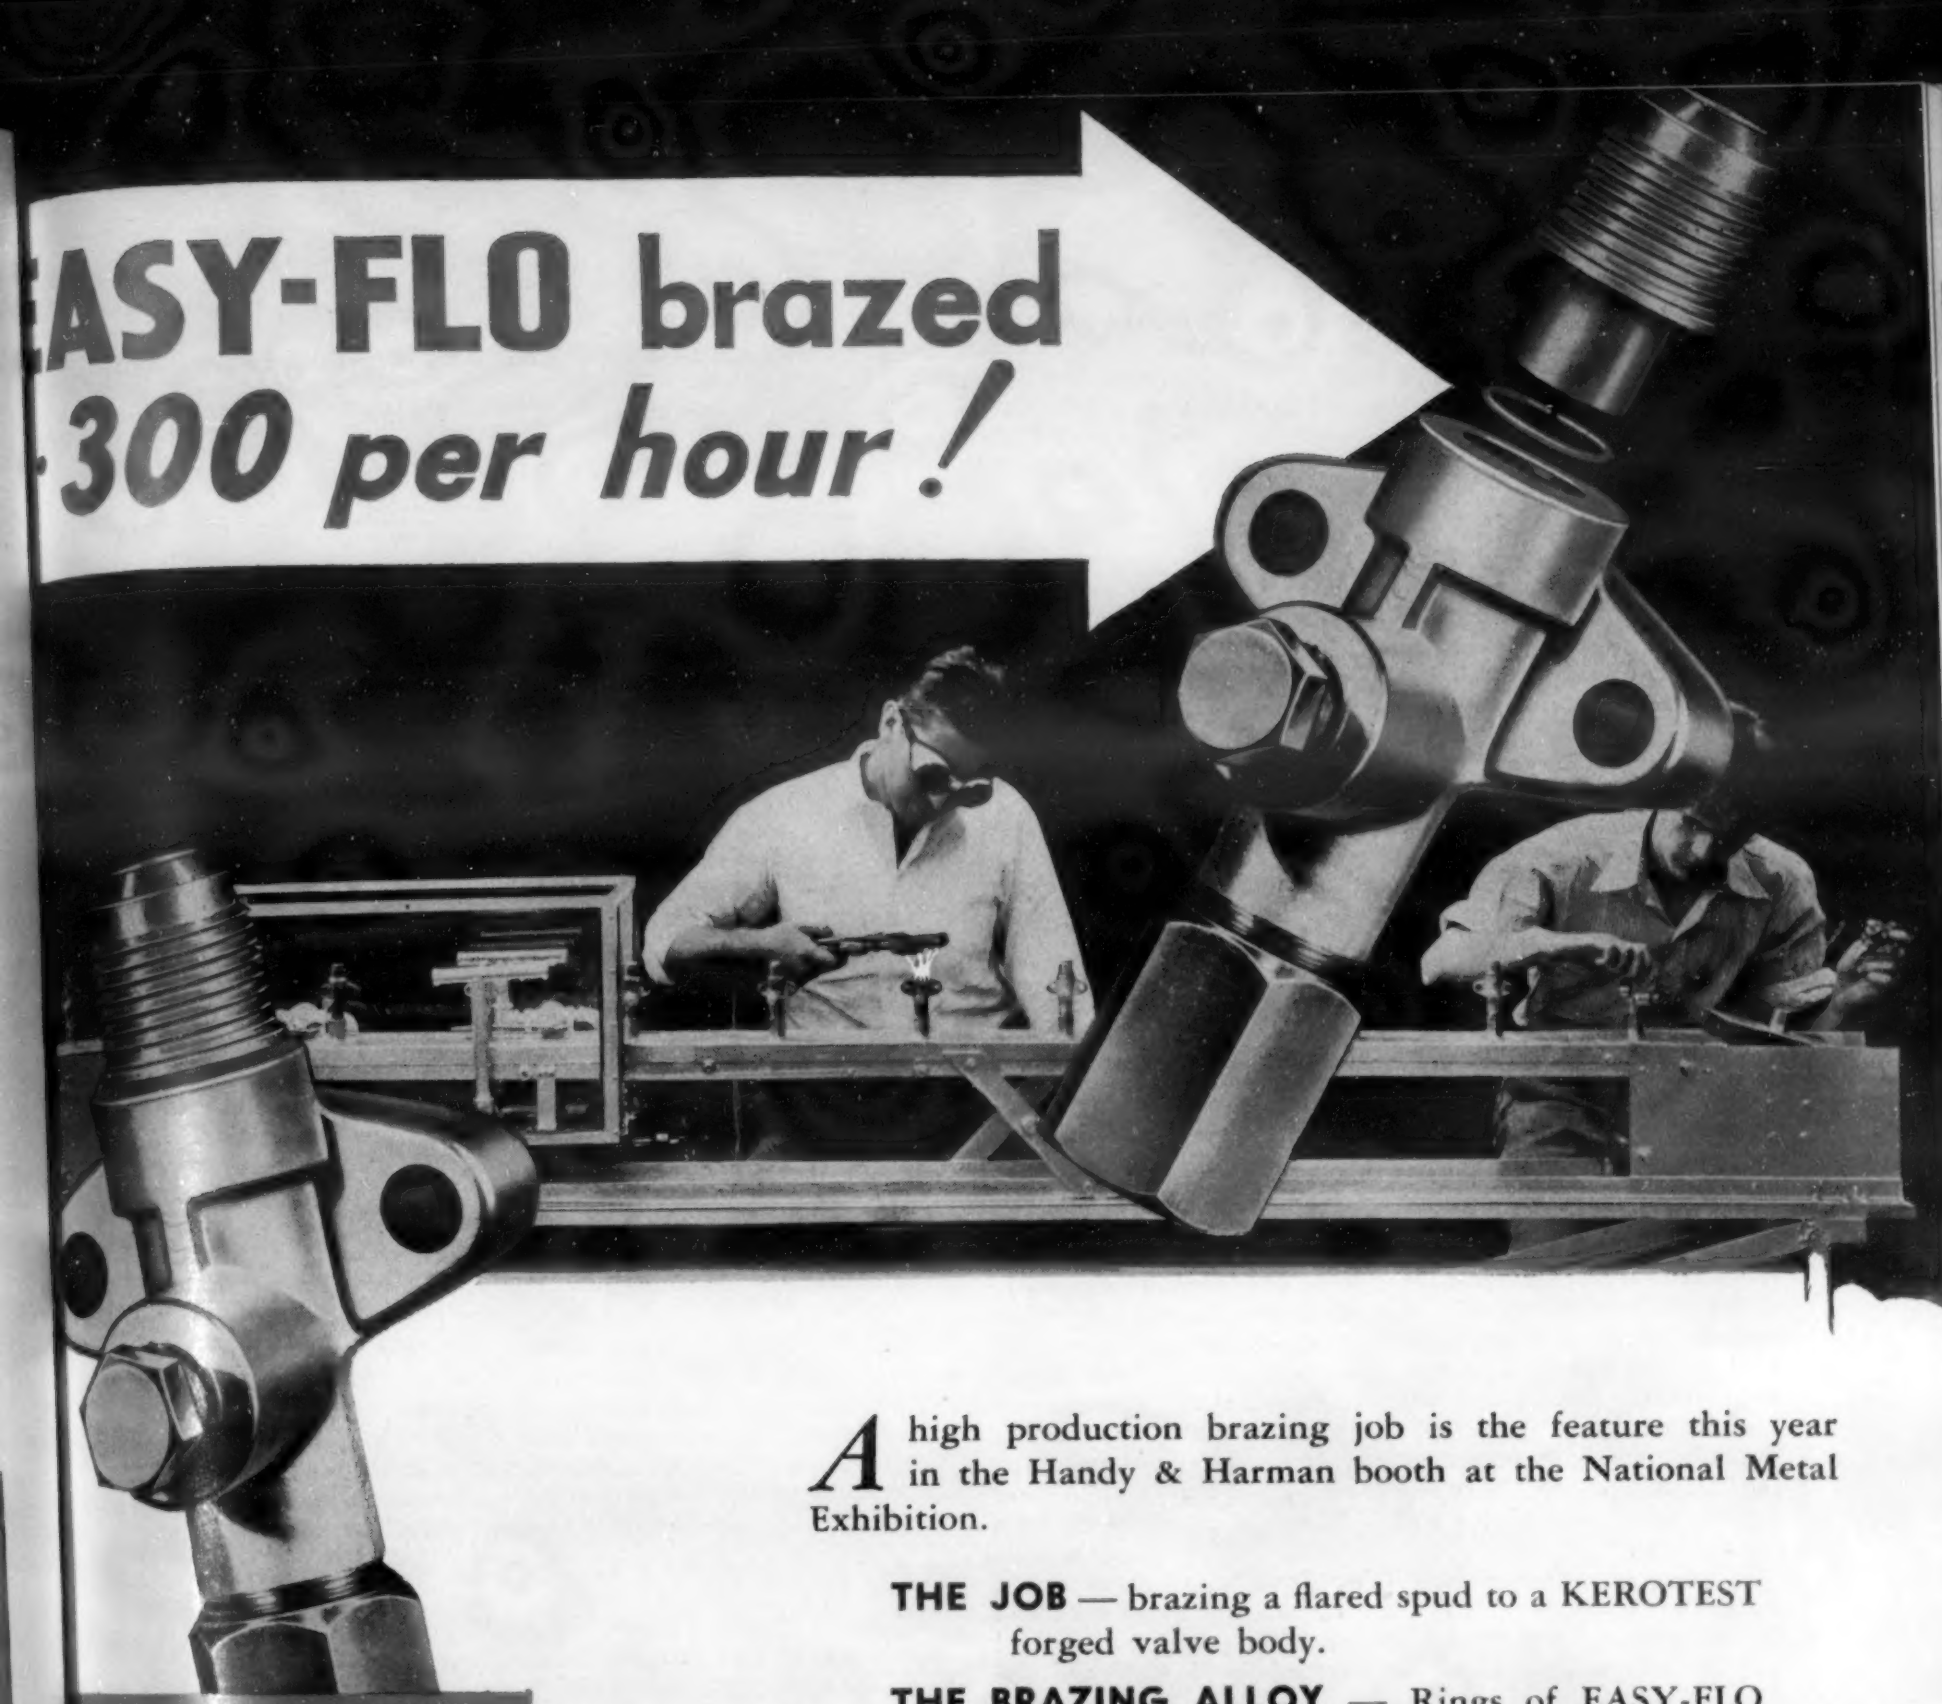
In the field of electrical conductors considerable progress has been made. The durability of the alloys used in electric heating elements has been increased several fold by detailed metallurgical improvements in the composition and processing of the various Ni-Cr-Fe alloys. New alloys of Fe-Cr-Al have been developed and used commercially at temperatures above the range of the conventional Ni-Cr materials. An alloy of iron and nickel, approximately 50-50, has been found very satisfactory for heating elements in hydrogen and hydrogen-nitrogen atmospheres for temperatures up to 1250 deg. C. and is in use in several large industrial furnaces. Ceramic coatings have been applied to tungsten and Mo-W alloy rods to provide resistor elements that may be operated in air up to 1500 deg. C. The future may bring some important applications of heating elements of this type.

Standard resistors play a very important part in electrical measuring instruments. The conventional material is "Manganin," a Cu-Ni-Mn alloy. Considerable effort has gone toward improving this class of material with respect to temperature coefficient and stability. One distinctly new material has been developed at the U. S. Bureau of Standards. This is a Au-Cr alloy containing approximately 4 per cent Cr and having a very low temperature coefficient of resistivity over a relatively wide range of temperature together with remarkable stability. It is coming into use for high-grade precision resistors.



High-strength high-conductivity copper-base alloys of the age-hardening type have been developed and used to solve various electro-mechanical problems such as those presented by large high-speed slip rings and spot-welding electrodes for example, as well as other electro-mechanical parts requiring material having electrical and thermal conductivities near to that of copper, the strength of structural steel and the ability to retain relatively high physical properties under prolonged heating at temperatures that would take all the starch out of work-hardened copper. Conductivities of the order of 85 per cent of that of pure copper together with tensile strengths near 75,000 lb. per sq. in. are now commercially available in certain Cu-Cr-Ag alloys. Higher hardness at the expense of somewhat lowered conductivity are provided by Cu-Co-Fe and Cu-Be-Co alloys. All these are heat-treatable alloys in which use is made of age-hardening phenomena to obtain the desired favorable conductivity-strength ratios.

Recognition of the effects of small amounts of silver in retarding the softening of cold worked copper has led to the use of cold-worked argentiferous copper ("Lake Copper") in commutators and some other places where operating temperatures may exceed those permissible with ordinary cold-worked copper.



Springs

In electrical apparatus, springs are often required to carry current and perform mechanical duties as well. Age hardened Cu-Be and Cu-Be-Ni alloys have come into use in some of the more exacting situations partly because of reasonably good electrical conductivity, but principally because excellent fatigue properties can be obtained.

Electrical contact materials have been the object of intensive study particularly by the telephone industry, and special alloys of silver, gold, palladium, platinum and iridium have been developed to meet special situations. Much of this work has had

ASY-FLO brazed 300 per hour!

A high production brazing job is the feature this year in the Handy & Harman booth at the National Metal Exhibition.

THE JOB — brazing a flared spud to a KEROTEST forged valve body.

THE BRAZING ALLOY — Rings of EASY-FLO made of 1/16" wire.

THE FLUX — Low temperature HANDY FLUX which is fully active at 1100° F.

PRODUCTION RATE — 300 joints per hour brazed, cleaned and cooled.

This production set-up shows clearly why low temperature silver brazing alloys are being used more and more to speed up production and reduce costs.

See this and other demonstrations if you visit the Metal Show — if you do not attend, *find out* what EASY-FLO and SIL-FOS can do on your work. Let us demonstrate their advantages in your plant, or send us parts to join in our laboratory. You can improve quality and lower metal joining costs on many kinds of work with these fast working, reliable brazing alloys. Write for full details.

EASY-FLO

—has the lowest flow point—1175 Deg. F.—of any brazing alloy making high strength joints. It flows freely, penetrates instantly between ferrous, non-ferrous or dissimilar metals, to make sound, permanent joints.

SIL-FOS

—flows freely at 1300 Deg. F., makes strong, ductile joints between copper, brass and bronze. It solves brazing problems for those who want reliable joints at low cost.

HANDY FLUX

—is liquid and active at 1100 Deg. F.—and is the only flux that lets you take full advantage of the flow points of these low temperature alloys.

to do with the careful adjustment or the composition of the contact material to the service conditions—there is no "best" contact material. Silver-graphite mixtures arrived at by powder methods have been quite important in circuit-breakers and have much to do with the success of the fuseless control panels for controlling and protecting the lighting circuits in homes and buildings.

Temperature Responsive Elements

The widening use of temperature-responsive elements in electrical control apparatus has led to the development of a great variety of thermostatic bimetals whose component alloys have been developed with an eye not only to mechanical properties and expansion characteristics, but also electrical performance. Special requirements as to resistivity and temperature coefficient as well as mechanical response to temperature changes have been met and the upper limit of operating temperatures raised. Some 20 or more distinct combinations are now in use, most of which have come out within the past 10 years. Most of the new component alloys are based on iron, nickel, cobalt and chromium. An exception is a high-manganese copper alloy said to have higher expansivity and better hot strength than brass.

Base-metal thermocouples have assumed a very important place in the control of industrial heating operations. Detail improvements of existing alloys and standardization have improved the picture here.

Vacuum Devices and Electrotechnology

Vacuum devices have played a very important part in recent electrotechnology. Getting electricity into the vacuum usually involves the attachment of metal to glass and is a perennial problem which has become increasingly difficult as the size of industrial electronic devices has increased. Recently new alloys based on cobalt, nickel and iron have been developed which can be sealed directly to modern low-expansion glasses to produce vacuum-tight lead-in structures. Alloys of this type have been applied with success in a variety of cases ranging from that of the all-metal radio tube to power rectifiers and the ignitron tubes used for timing the power impulses in "spot" and "shot" welding operations now so extensively used in joining the parts of all sorts of things from "five and dime" gimcracks to streamlined stainless steel railroad cars and light weight structural elements for skyliners.

In power transformers and other large electrical apparatus, internal electrical connections must be so made as to withstand the temperatures and stresses that may be set up by overload and short-circuit conditions. To meet this need, Cu-P and Cu-Ag-P brazing alloys have been developed. These have melting points intermediate between those of Pb-Sn solders and conventional brazing alloys and are very convenient for producing high strength joints between copper parts particularly when the jointing must be done in a confined space as in some assembly operations.

As to the Future

Perhaps a review should be followed by a forward look—we believe we now know, even unto the uttermost isotope, almost everything we will ever have upon which to build compositions of matter. However, new changes will be rung while of the old we will still be learning surprising things. If we estimate the number of unexplored compositions, consider the new tools of investigation, theoretical as well as experimental, now at hand and note the increasing tendency to specialization of materials for specific use, we may well feel confident that the next decade will see progress comparable to that of the last,, perhaps by the summation of numerous small steps as compared with the broad jumps of the past 30 years but nevertheless progress which will be apparent in our everyday lives.

Electric Melting of Non-Ferrous Metals and Alloys

by G. H. Clamer

The depression, extending over practically the entire period of the past decade, 1930-1939, has presented industry with many new problems. The non-ferrous industry has not escaped these.

Except at the beginning, during the prior decade (1920-1929), aptly characterized as the "golden glow," industry was concerned mainly with problems of maximum production. During that period many electric furnaces were installed. Many fuel furnaces were replaced under conditions which were such that an electric furnace was not justified. In some cases electric furnaces of a type not best suited for the particular requirements were installed. In other cases the then existing tonnage melting requirements were sufficient to justify the installation of an electric furnace, but during the depression this no longer held true.

The Standby Charge

The experience during the depression led to exhaustive study of melting technique and equipment. Maximum economy was the keynote stressed by management. In seeking maximum economy melting costs were studied. The so-called standby charge of the power companies called for complete investigation. This was one of the many items of overhead to which the managerial finger pointed. During the period of the "golden glow," with its high rate of production and its consequent large divisor, this item attracted little if any attention. As furnace operating hours were reduced, and particularly during periods of complete shutdown, the item of standby stood out in bold relief.

In the wrought brass industry, due to difference in operating conditions as compared with those prevailing in the brass foundry, but mainly because of the more favorable relationship of standby to actual power used, the problem of standby was not so serious. There have been no reports, to the writer's knowledge, that any of the electric melting equipment in the wrought brass industry has been discarded in favor of fuel melting equipment.

Fuel Furnaces in Small Brass Foundries

Many electric furnaces in small brass foundries have been replaced by fuel furnaces during the past decade, mainly because of the continuing standby charge during shutdown or low production periods. In some cases power companies voluntarily during stated short periods eliminated the standby charge. This action no doubt was responsible for the retention of a number of electric furnace installations that would otherwise have been discarded. In the foundries normally having a large production the conditions were more favorable and approximated the conditions prevailing in the brass mills. No large installations of electric furnaces, so far as the writer knows, have been abandoned.

During the period of the "golden glow" little if any attention was paid to the matter of power factor, the emphasis always being on tonnage production per day. Improvement in power factor has been accomplished through better designing of electric furnaces, but more particularly through the installation of power factor corrective equipment such as static condensers or synchronous motors. Suitable static condensers were only beginning to be used 10 years ago. Static condensers are today in quite extensive use for this purpose.

Larger Capacity Furnaces

Another trend during the past decade has been toward furnaces of larger capacity. This is particularly true in the wrought brass industry. This trend has followed the development of high speed metal working equipment such as, for example, improved strip mills, larger extrusion presses, tube making equipment, etc. Melting of zinc and copper in some cases has called for large melting units, viz, capacity of 10 to 20 tons. In these fields the electric furnace has justified its use, not only from the standpoint of economy, but improvement in the quality of product. No demand for larger furnaces in the brass foundries has arisen. In the foundries producing castings requiring large single batches of metal at irregular intervals, fuel furnaces are best suited.

The use of the electric furnace has extended in the field of melting precious metals, thus proving its merit in that field.

In Europe many furnaces for melting aluminum have been installed. A few of these have been of the resistance type—all the others of the submerged molten resistor induction type. Ingenious devices for cleaning the resistor channels of adhering skull have been devised. This in the past has been one of the serious objections to the induction type. There have also been a number of high frequency coreless induction furnaces installed for this purpose, as well as for melting nickel and nickel-base alloys.

Advantages of Electric Melting

To determine if electric melting may be advantageously used, the following should have most careful consideration:

(1) Weekly quantity to be melted.
(2) Probability that production will be maintained at nearly the estimated rate.
(3) Power demand charge for the minimum hourly output for which the equipment may be used.
(4) If penalty may be imposed due to low power factor.
(5) Original cost of equipment and installation thereof, including all appurtenances.
(6) Probable operating cost including repairs, refractory, labor, metal losses, etc.
(7) The possibility of operating two or three shifts per day, thus reducing space requirements to a minimum.
(8) Can quality of product be improved or end cost of finished product reduced?
(9) Advantages resulting due to improved working conditions.

In the wrought brass industry answers to the above questions have been such as to warrant the installation of additional units to existing installations and the few remaining fuel furnaces have been almost completely replaced by electric furnaces. Electric furnaces are now melting practically 100 per cent of the metal melted in that industry.

Aluminum and Magnesium

by Junius D. Edwards

The last 10 years have been a period of progress in the aluminum industry and research has played an important part in this advance. Even when general business activity was low, research on aluminum was being pushed vigorously. These few paragraphs do not permit much detail, but the broad trend shows countless new applications of aluminum made possible by research.

Aluminum

The fundamental investigations of the previous decade have borne fruit in the new aluminum alloys developed and put into production during the past 10 years. The slogan, "Nature made aluminum light, but research made it strong," aptly characterizes this development. New aluminum alloys of greater strength, new aluminum alloys of superior serviceability in salt water and other environments, new aluminum alloys for special services, all have increased the usefulness of aluminum and have been an important factor in its steadily increasing industrial application.

The most striking examples of these new uses are the structural applications. Stream-lined aluminum trains of high speed are now almost a commonplace, although the first one was a great novelty.

METAL POWDERS
ALLOY POWDERS
CHARLES HARDY INC.
415 LEXINGTON AVENUE NEW YORK, N. Y.

Previous experience with aluminum in railway car construction helped make the first stream-lined aluminum train an instant success. Aluminum has proven itself indispensable in a world where speed and safety are prime elements in transportation. The transport airplane of today has 80 to 90 per cent of its structural weight in aluminum alloy.

With aluminum alloys a standard structural material for trains, buses and airplanes, aluminum is now entering the field of marine transportation, and this should be one of the applications in which important advances will be made during the next decade. The increasing uses of aluminum in architectural applications and in the chemical and food-processing industries must be at least mentioned.

The many structural applications of aluminum alloys have had a firm foundation laid by Aluminum Research Laboratories in their investigation of the fundamental problems involved in building strong, but light, structural members. The engineer now has available in its second edition, a Structural Aluminum Handbook to guide him in matters of engineering design.

In making aluminum more useful, the field of finishing has not been overlooked. A striking development has been that of anodic coating, so well represented by the "Alumilite" and "Alzak" processes. All types of finishing processes such as painting, plating, and anodic oxidation have received the benefit of continued research and have done their bit to make aluminum more useful, both by way of decoration and by increased protection.

Magnesium

The last 10 years have seen the producers and fabricators of magnesium in an active search for markets. The use of magnesium has been stimulated by price reductions which have brought its price per cubic foot down to that of aluminum. Research has been pushed as well, and the increased consumption of magnesium is largely due to technological advances in the fabrication of the metal. These are of a broad character and include the development of magnesium alloys with improved mechanical properties and stability. Economies have been made in such fabricating processes as extrusion, sand and die casting, and forging, including the ability to make magnesium alloy products of large size and complicated design by these processes. For many services magnesium must be protected, and research in this field has led to better coating and painting methods for protecting magnesium. The magnesium consumption curve points sharply upwards.

Alloy Steels

by H. J. French

Significant changes have occurred in the alloy steel industry during the past 10 years, but only a few of the broadest trends can be mentioned, due to space restrictions.

The automobile industry still is the largest single consumer of wrought alloy steels, but this industry's proportion of the total consumed in the United States has decreased during the past eight or 10 years. This does not signify a loss in markets, but that alloy steels have assumed a more important role in other industries. (Annual Statistical Report, 1938, American Iron & Steel Institute.)

The distribution, by types of product, likewise has changed. The proportion of hot and cold finished bars, while still accounting for more than two-thirds of the total alloy steel produced, has decreased, while the percentage in sheets and other flat rolled products has increased.

The broadening of the markets for alloy steels is, no doubt, due to a variety of favorable factors, although probably they are all allied with the fact that alloy steels, as a class, can serve economically to defeat the destructive forces encountered in industrial machinery and equipment. In addition to providing higher strength per unit of weight (or bulk) without impairment of safety, alloy steels permit improvement in resistance to fatigue, corrosion, wear, the weakening effects of elevated temperatures and the embrittling effects of sub-atmospheric temperatures.

Stainless Steels

Outstanding in the record of progress of the last 10 years has been the commercial development of the stainless steels containing chromium or chromium and nickel, with or without additions of other elements. Volume has taken a marked upward trend, as shown by the fact that in 1929 ingot production of all varieties was about 48,000 net tons, while in 1937 it exceeded 150,000 net tons. At the present time, over 40 varieties are recognized in the American Iron and Steel Institute *Steel Products Manual* covering stainless steel type numbers and composition ranges.

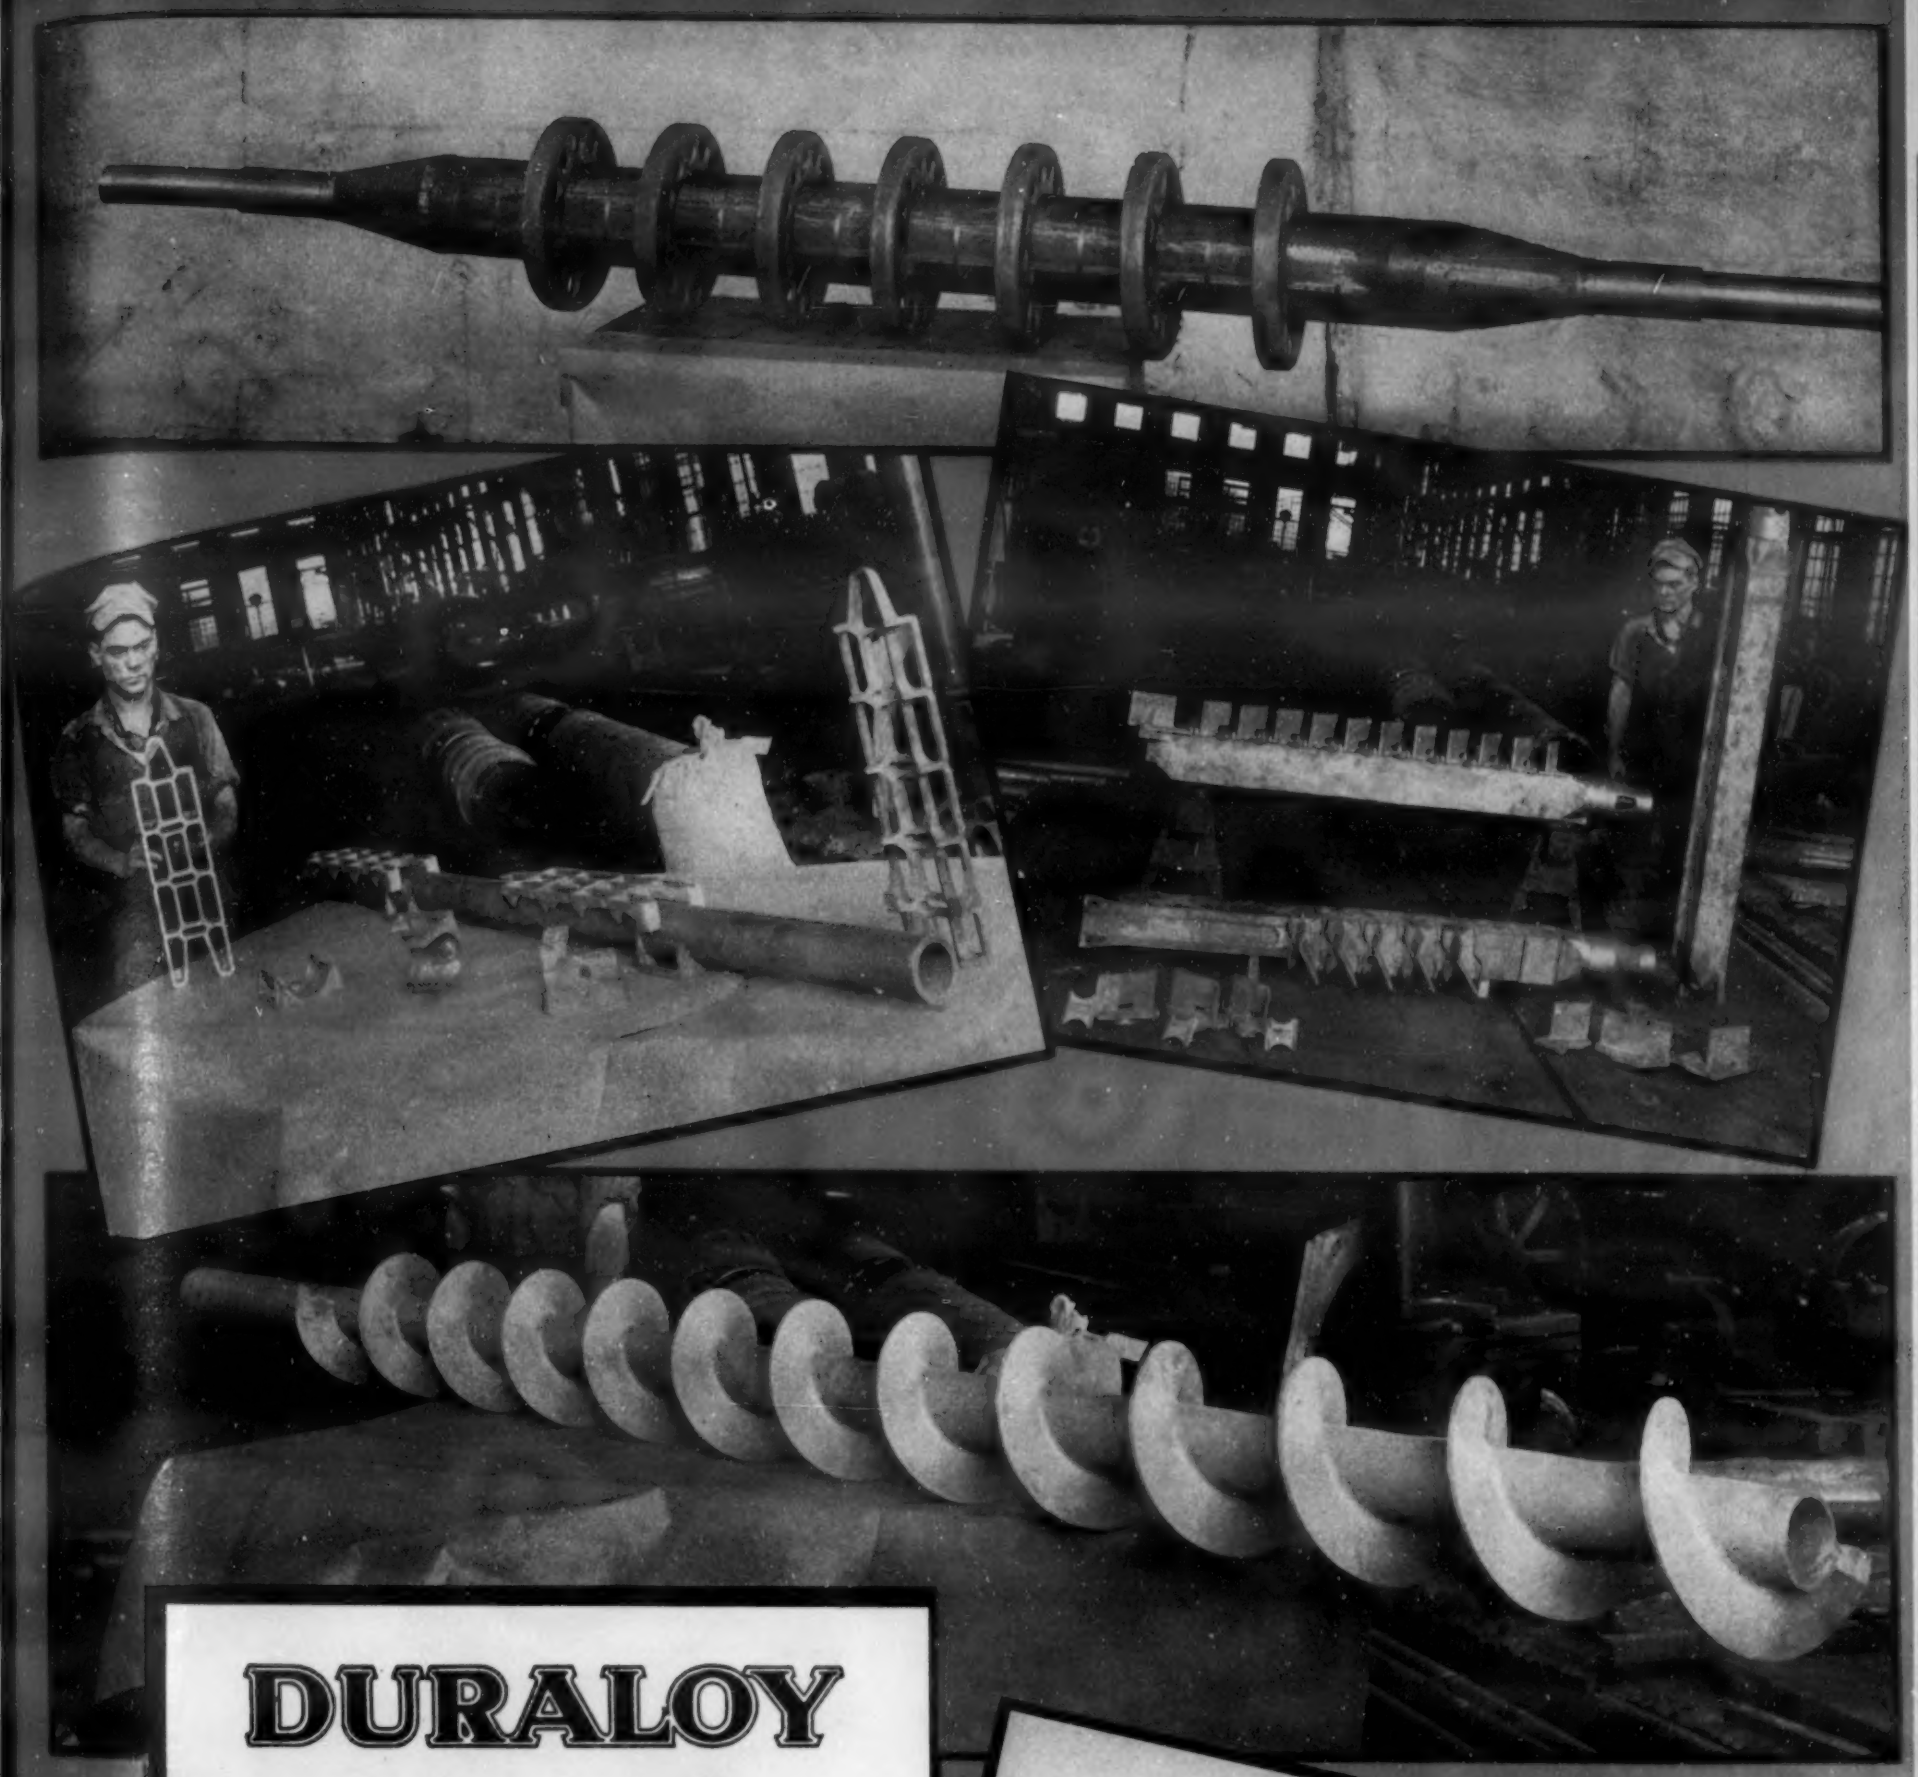
The uses of the stainless steels in architecture and industrial equipment, where advantage is taken of their resistance to corrosion and staining, have been supplemented by their application in transportation units where high strength and satisfactory fabricating qualities have been added requirements.

The stainless steels have disproved the old concept that ferrous metals were primarily of value for their strength and hardness, while the non-ferrous metals provided resistance to corrosion.

Process Control

Process control, which, in its broadest sense, includes everything that contributes to the consistent procurement of desired performance qualities, is fundamentally a part of steel making, but it is especially valuable with alloy steels.

Improvements in technique involving co-ordination of many steps from scrap selection to slag control, methods of deoxidation, and conditions of working have been responsible, in a large part, for improved economy in the applications of alloy steels in certain markets. A part of this picture is reflected in what is commonly termed "grain size control," whereby steels of a given type can now be made to show consistently uniform performance qualities and response to treatment.



The improvements resulting from process control have made possible readjustments downward in alloy contents for many heat-treated parts of small or moderate section and substantial economies have resulted. For example, with grain size control, certain steels, when formed into gears, show low distortion on hardening, and this can be kept within close tolerances in production, reducing scrap, remedial operations, etc. The superior toughness of fine-grained carburizing steels and their resistance to grain coarsening at carburizing temperatures permit direct quenching, often with economy and superior performance.

Many problems remain concerning process control. One of these, of current metallurgical interest, relates to two different practices now in use in automobile construction. In the one, steels are used which, while fine grained, will harden to a high degree throughout the entire section. Penetration of hardening is desired prior to tempering. In the other, fine grained steels with small alloy additions and often increased carbon contents, which are shallow hardening, are employed. High surface hardness but low penetration is the rule. Only time can reveal which of these practices provides the best performance or whether both may be used.

Low Alloy, Strong, Corrosion-Resisting Steels

An important development of recent years comprises a group of alloy steels especially suited for fabricated structures, for which combinations of the following requirements have to be met: (1) Moderate cost, (2) improved strength properties in the rolled, normalized or annealed conditions, (3) ease of fabrication, including cold forming and welding, and (4) improved resistance to corrosion.

Practically all of the current commercial types contain less than 0.25 per cent carbon and under 1 per cent manganese, when produced in flat products or structural shapes. All of these steels contain copper between about 0.4 and 1.5 per cent. A majority of the group, at present, are of the copper-nickel alloy

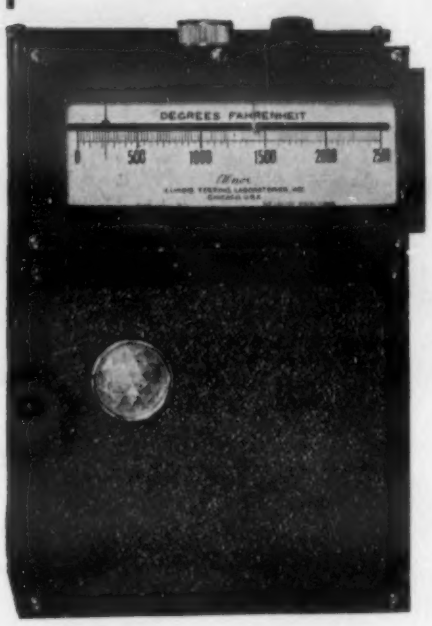
DURALOY

THE *Experienced* ALLOYS

Flexibility of Duraloy's production facilities and versatility of its metallurgical service are well illustrated by the different castings shown here. Large or small, intricate or simple, rough or mirror finish... the range of Duraloy alloy castings is certainly extensive. A battery of modern electric furnaces of widely varying capacities permits this range in casting sizes. As for the "experienced" part, Duraloy castings have been on the market since 1922; centrifugal castings since 1931. Each is a pioneer in its class. Why not drop in when at the Metal Show in Chicago and tell us about your problems involving heat, corrosion or abrasion? Our Booth is N-301.

THE DURALOY COMPANY

Office & Plant—Scottdale, Pa.



NEW YORK PITTSBURGH

BE SURE TO SEE

THESE "ALNOR" INSTRUMENTS

AT THE METAL SHOW!

Chicago, Oct. 23-27, 1939

THE "ALNOR" PYROMETER CONTROLLER

Operating on electronic principle similar to a radio, the "Alnor" Pyrometer Controller guarantees hairline temperature control of heat treating furnaces, melting pots, ovens and other heating devices. There are no motors, depressor bars or contacts to stick or become inoperative. The Indicator is free at all times to give continuous indication and control. A red bull's eye indicates whether heating unit is on or off. It controls directly electric heat, oil or gas fired units with motorized or solenoid valves. Wide usefulness and results more than compensate its moderate cost.

"ALNOR" PYROCON FOR SURFACE TEMPERATURES

A combination surface temperature pyrometer designed to give almost instant extremely accurate readings.
Quickly interchangeable thermo-couples, each suited for a particular purpose assures accurate temperature readings on Revolving Rolls, Platens, Molds or Plastic Surfaces.
The Pyrocon is a self-contained portable instrument, light, handy to use. Variable adjustments allow thermo-couples to be placed in almost any desired position in relation to the indicator, permitting easy contact with the heated surface. The "Alnor" Pyrocon does the job of two or more ordinary instruments, yet is extremely low in price.

"ALNOR" PORTABLE TYPE 1750 PYROMETER

A handy, reliable, direct reading millivolt type pyrometer. Has sufficient internal resistance to permit a small variation in the length and size of the thermo-couple and connecting wire without affecting the accuracy, yet it is low enough to allow for unusually rugged movement. The "Alnor" Portable Pyrometer, for general temperature measurement, is ideal for small commercial laboratories where an inexpensive pyrometer is desired.

If you are unable to attend the Metal Show, write for catalog describing these and other "Alnor" instruments.

Illinois Testing Laboratories Inc.

425 N. LaSalle St. Chicago, Ill.

type, with or without reinforcement from other elements such as chromium, molybdenum, or increased phosphorus content. Silicon-chromium-copper steels are represented in the current commercial varieties, as are specially processed steels containing copper and increased phosphorus.

Minimum yield points of 65,000 lbs. per sq. in. can be secured in some of these steels in certain size ranges, but usually 50,000 lbs. is the minimum specified, since the elastic moduli of all ferritic steels is the same and higher properties do not necessarily bring proportional advantages to the engineer.

Since their commercial inception about five years ago, such steels have been produced in increasing amounts and their applications have become diversified. Their value, as a group, is chiefly associated with their "high strength properties" at quite low carbon contents, which permits ease of cold forming and welding, but combined with this is improved corrosion resistance in the atmosphere and certain other environments.

Free Machining

Alloy steels made especially to provide improved machining qualities have become more widely used. This applies both to the constructional steels and the stainless steels. Sulphur, as the addition agent to provide free machining, has been followed by selenium (or tellurium) and lead. Any one practice may not provide attractive improvements under all conditions, but the free machining alloy steels have become firmly established and have contributed definitely to an extension of markets.

Age hardening effects, long utilized in the non-ferrous metals, have become useful only recently in the steels. The low alloy, corrosion-resisting steels containing more than about 0.75 per cent copper, and Nitralloy N, containing both aluminum and nickel in suitable proportions, respond to age hardening treatments. Use has been made of age hardened copper-nickel steels (A. E. Gibson: "Nickel-Copper High Strength Steels Meet Specifications of Welded Construction," *Steel*, January 25, 1937, p. 34) in welded structures which, because of size and shape, could not be quenched and tempered without difficulty.

Welding, Selective Treatment, and Surfacing

Marked advances have been made in the welding art and in the development of methods of flame hardening, hardening after induction heating, and in the surfacing of metals for resistance to wear and erosion. These developments have helped to provide alloy steel parts better suited to meet modern requirements, and they have been reflected in the markets for alloy steels.

Welded alloy steels are found in a variety of industries, including automotive, railroad transportation, power, shipbuilding, oil, etc. Welding has played a part in the effective utilization of the special properties of alloy steels in pressure vessels for high temperature service or for low temperature dewaxing of lubricating oils, while hard surfacing applied to alloy steels has provided improved performance in parts of equipment for oil well drilling, mining, and excavating.

Conclusion

The selected items represent only some of the major trends. Our knowledge, both general and specific, of the effects of alloys in steels has improved, so that today we are in a better position to meet the advancing requirements of industry. Better steels are available for resisting corrosion, fatigue, creep at high temperatures, embrittlement at low temperatures, and wear. Much more remains ahead, but the record of the past 10 years is one of measurable progress in our efforts to gain a better mastery of the metallurgy of the alloy steels.

Steel Castings

by John Howe Hall

During the past 10 years, the industry has perfected technique for casting the heat and corrosion-resisting chromium and nickel-chromium alloy steels, especially the 18 chromium-8 nickel, 25 chromium-12 nickel, and 15 chromium-35 nickel grades. By suitable modifications in the silicon and manganese content, which usually run higher than in the corresponding rolled products, the sluggishness of these metals, which at first made the problem of casting them extremely difficult, has been largely counteracted, so that satisfactory castings are produced.

In many shops, the problem of continuously securing satisfactorily low carbon content in the alloy steels, and at the same time remelting the heads, gates and risers, has been solved by the use of the Ajax-Northrup type high frequency melting furnace.

Aluminum Embrittlement

For a number of years, so-called "aluminum embrittlement," especially in acid electric cast steel, had plagued the maker of small steel castings. The trouble consisted in low ductility in a certain proportion of the heats produced. Lillequist, Sims and Dahle have carried on research work looking to the cure of this difficulty, and the two latter have now perfected a method by which the trouble appears to be obviated, while the use of aluminum to promote soundness in the castings is continued. Corroborative evidence has been contributed by Gagnebin. This is a most valuable contribution to the art of steel casting manufacture.

The production of heat-treated low-alloy cast steels has been brought to a high state of perfection, and these grades of steel are recognized in standard specifications of the American Society for Testing Materials, No. A 148-36. By a combination of judiciously chosen alloy content, and suitable heat treatment, cast products of very excellent physical properties are regularly produced, of a grade that would formerly have been supposed impossible of attainment. Oil and water quenching of steel castings, once thought impracticable, is now a regularly recognized procedure in well equipped foundries.

Differentially hardened steel castings, with hard areas to resist wear and strong, tough body portions, are extensively produced to meet severe wear conditions coupled with heavy stresses. Flame hardening with oxy-acetylene or other gas torches fits excellently into this phase of casting manufacture.

Castings in Welded Parts

The use of steel castings as constituent parts of welded assemblies has made continuous progress. This year, the American Society for Testing Materials has recognized the availability of weldable grades of steel castings by the adoption of tentative specifications for carbon steel castings of weldable grade for miscellaneous industrial uses (A215-39T), and two tentative specifications for carbon and alloy steel castings of weldable grade for service at temperatures up to 850 deg. F. and from 750 to 1100 deg. F. respectively (A216-39T and A217-39T).

With the improvement of welding technique and the rapidly expanding utilization of radiography to test the soundness of castings and of welds, repair of castings by welding has been recognized as a legitimate part of the manufacturing process, and countless castings are now salvaged by proper welding repair, that customers would have refused to accept not so many years ago.

At the same time, great progress has been made in eliminating unsoundness, by studies with radiographic methods, so that defects formerly unsuspected or ignored are now commonly avoided by the examination of pilot castings made to test foundry methods, before undertaking quantity production. In the case of very important castings, such as valves and fittings in power houses, oil distilling plants, etc., all castings produced are sometimes subjected to radiographic examination.

Production of very large integral castings for railroad and industrial use has made steady progress, and castings are now

AB POLISHERS

FOR METALLURGICAL LABORATORIES

Solve the problem of efficient, economical sample preparation. Vibrationless operation and selective speeds eliminate pitting. Interchangeable 8 inch diam. polishing discs increase peripheral speed latitude. Sturdy construction, comfort, and convenience have contributed to their unequalled popularity.

See Booth B-120

A-B STANDARD POLISHER

Selective speeds 575 and 1150 r.p.m. Vertical radial, and thrust ball bearing motor.

A-B LOW SPEED POLISHER

The ideal solution where slow speed polishing is required. Operates at 250 r.p.m.

being marketed regularly to replace what were formerly fabricated assemblies. The ability to furnish long integral structural members whose main portions vary continuously in thickness from ends to middle, thus putting the heaviest portions where the greatest stresses occur, with a considerable saving in weight, is a contributing factor in sending this business to a foundry. The intricacy and completeness of many of the modern one-piece railway castings, such as car trucks, integral tender frames, locomotive beds, etc., is almost beyond belief, and would have been voted the dream of impractical visionaries, not so many years ago.

Centrifugal casting of tubular parts of varying size and length, and of gear blanks and similar shapes, has been developed on a commercial scale in several shops. Castings of this type are made in carbon, low-alloy and high-alloy steels, with a considerable saving in heads and gates, and a marked improvement in soundness.

Molding Processes

Two molding processes have been introduced from abroad, both of which have attracted considerable attention. The details of one, the Fisher method, have been jealously guarded as a trade secret, known only to those using the process. The other, the invention of Jean Baptiste Durand, and known as the Randupson process, has been described freely by the American representatives of the owners of the patents, and has been the subject of extensive discussion in foundry circles. Briefly, the method consists in using cement and water as the sole binders for the sand or other refractories, and is said to secure many of the advantages of dry sand methods, at a cost approximating that of green sand molding. The process is applied to steel, iron and non-ferrous work, and it is claimed that by its use castings are produced superior in accuracy and appearance to what are secured by other methods.

Notch Effect in Testing Steels

by S. L. Hoyt

The question of the effects of a notch on the behavior of stress-carrying members has two aspects—one dealing with parts subjected to fatiguing stresses and the other with parts subjected to single overloads which either break the part at the notch or cause it to deform.

During the past 10 years considerable work has been done in both fields, so that now it should be possible to begin to crystallize our thinking in each. In particular it has become clear that no direct correlation exists between these two types of notched bar tests. Steel with good tensile properties may be either tough or brittle in a single-blow notched-bar impact test while the behavior in notch fatigue may be good or bad (though with less variation) whether the single blow notched bar test results are good or bad.

It has been known for years that the surface condition and contour have important effects in reducing the fatigue strength, but it is of only recent date that such observations have stimulated quantitative investigations of the effects.

Better Understanding of Notch Effects

It may still be too early for appraisal, but in the past 10 years there has come a material improvement in our understanding of notch effects and the ability of steels to retain ductile behavior when notched. Metal being fatigued (a progressive cleavage phenomenon) is being plastically deformed and work hardened. In contrast to the common types of plastic deformation, which have been so extensively studied, in fatigue the metal is

DEFY HEAT AND CORROSION

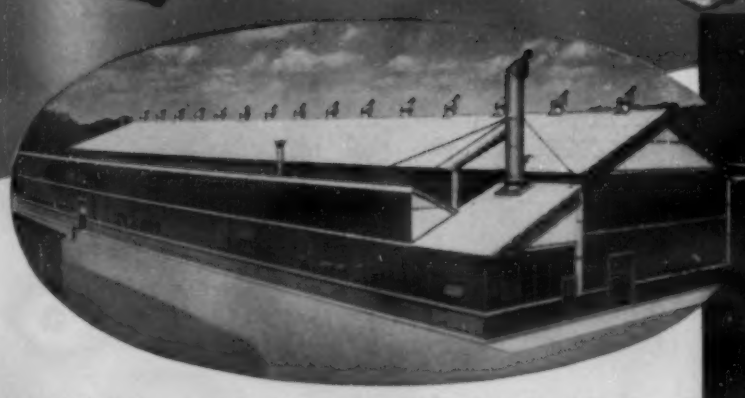
Fahrite Heat and Corrosion Resisting Alloy Castings have been meeting the most savage attacks of heat and corrosion successfully for more than 17 years. Fahrite has the built-in quality to meet the demands placed upon it daily by corrosive conditions in the chemical processing and oil refining industries.

All ranges of Chromium, Chromium Nickel and Nickel Chromium with additions of Molybdenum, Columbium and Titanium are available in Fahrite Corrosion Resisting Alloys to suit particular service conditions in your plant.

Our modern laboratory facilities are available for your use. Let Ohio Engineers cooperate with you. We welcome your inquiries.

FAHRITE

HEAT AND CORROSION RESISTING ALLOY CASTINGS



Fahrite Conveyor trays.

Standard and special chain patterns available.

Fahrite box and tray used in the largest malleablizing furnace now in operation.

Fahrite carburizing boxes and trays available in all shapes and sizes.

Fahrite carburizing retort.

Fahrite is produced in the most modern and best equipped foundry in the country.

stretched and compressed (for reversed cycles) with a large total or summated deformation but with only minor changes in shape.

The behavior is particularly important when a notch is present because the metal at the root of the notch, and to some depth below and along the sides of the notch, is worked backwards and forwards by a kneading action. Experimental determination of deformability, which controls the size of stress peaks developed, requires new technique and to this end a micro-extensometer has been developed (E. Lehr, Metallwirtschaft, Vol. 18, July 7, 1939, p. 595) with which a magnification of 100,000 times or even 1,000,000 times can be secured.

Considerable work has been done to discover what relationships there may be between the results of the tensile test and notch fatigue behavior. Comparing the tensile strength with the fatigue strength, the fatigue strength to tensile strength ratio usually comes within the limits 0.4 to 0.6. While this can hardly be considered sufficiently constant for design purposes, the establishment of an approximate ratio is useful in selecting steels and treatments.

Fatigue Tests in a Notched Condition

A more practical, and direct, line of attack has been the use of fatigue tests of various materials in a notched condition. One of the findings has been that a notch, like a corrosive attack, lowers the fatigue strength drastically and tends to level off the fatigue strengths of a steel in various conditions though the tensile strength varies considerably.

The assumption has been made by some experimenters that the drop in fatigue strength is solely a function of the notch (size not being considered) but comparisons of different steels in response to the same notch conditions have shown that the actual notch fatigue strength is a complex function of both material and notch effect.

There has been an attempt to clarify this situation by arriving at a notch sensitivity factor in a different way. If we divide the maximum stress at the root of the notch by the calculated mean stress over the root section we get a *shape factor* by which the fatigue strength would be lowered if stress were the only factor. Now it appears that this is an unusual case, or the limiting case, for the notch-fatigue strength is usually found to be above such a calculated value. By dividing the fatigue strength by the experimentally determined notch-fatigue strength the actual *notch effect factor* is obtained, which shows the amount by which the fatigue strength actually was lowered. The *notch sensitivity* of the material for the notched bar used is then obtained as a function of these two factors. If this analysis of notch-fatigue behavior is ultimately shown to be correct it will mean that the notch does not injure the metal (i.e. make the metal fail at an actual or true stress which is less than the fatigue stress) but in this sense may actually improve its behavior.

Size of the Part

Another factor which appears to be of importance is the size of the part, in plain fatigue and in notch-fatigue. One recent report on railroad axles suggests that a full sized axle at about 7-in. diameter had a fatigue strength about half that of 0.3-in. diam. bars taken from the surface of the full-sized axle.

There is now a serious attempt in Germany to formulate these notch effects and size effects as a new system of mechanics, called "material mechanics." This term distinguishes between the new mechanics and the old mechanics or theory of elasticity and signifies that the behavior of the part (mainly plastic behavior) depends on the material of which the part is made in its responses to stress concentrations and size effects.

Notched Bar Impact Testing

Upon turning to the older type of notched-bar testing, we come to a field which, in laboratory tests, is sharply differentiated from notched-bar fatigue testing. The feature of the behavior is a sudden and usually complete fracture through the notch section. The likelihood of failure of this type in the ductile steels cannot be predicted from the tensile test and this circumstance has led to a very considerable study of the notched-bar impact test. The work of the past decade has contributed materially to a better understanding of this field.

Commensurate with the importance of the notch effect, or possibly with our lack of understanding, a number of important meetings have been devoted to its consideration. After the Zurich meeting in 1931 of the New International Association for Testing Materials, the French test bar (10 mm. bar with 5 mm. notch) was adopted as the standard small bar, the test temperature to be about 70 deg. F. Although this standardization guarantees uniformity of test results in all countries using the standard bar, the test that was adopted merely samples the behavior of the steel at one temperature and one striking velocity, with one specific notch effect. To students of notch behavior it must be clear that considerable more work is necessary on the development of an adequate test procedure and on correlations with service behavior. A start along this line has been made.

The ASTM held an important symposium on notched bar and impact testing at its 1938 meeting, which covered both practical and theoretical aspects. Among other things it was recorded by Messrs. Riegel and Vaughn that notched bar testing has been highly successful in controlling the purchase of steel and subsequent fabrication into parts subject to very trying service. The writer proposed that the level of the cohesive strength should be obtained by means of the "match" point, at which the steel changes from ductile to brittle behavior. Two steels can have closely the same impact value in the standard test, or even the same notch toughness, and yet vary considerably when tested at a lower temperature or with a different notch effect. The writer also proposed the use of a modified Moser test which is based on the 10-mm. bar, instead of the 30-mm. bar, with the width varying from one half to three normal. Results obtained by this method at the General Electric Co. and the Caterpillar Tractor Co. were contributed to show its utility.

Finally, a more complete analysis of the behavior of a steel can be made by recording the stress-strain relationships during fracture. Schuster, at the memorable 1937 meeting of the Manchester Association of Engineers, observed that the point of crack formation gave indications of the resistance of the steel to crack formation and to the spreading of the crack, once formed.

It is clear that mere agreement on the small Charpy bar as a standard test bar and on room temperature as a standard test temperature is only a start, though a highly desirable step. The urgent need is a precise testing procedure which is capable of predicting the probable behavior in a particular service. Whether the number of failures in service due to deficiency in notch toughness is large or small, the engineer should be able to guard against this type of failure by design and selection of materials, and do it on a "sound engineering basis."

Metals in Airplane Construction

by J. B. Johnson

A decade ago wood, alloy steel and aluminum alloys were used in approximately the same amounts for airplane construction. Today metal is used almost exclusively where high performance is the goal and is receiving more attention in the field of the cheaper, light commercial airplane.

Preponderance of Aluminum Alloys

Metals are very adaptable to the design and fabrication of the smooth, stressed skin monoplane which has become the standard

Safeguard Your Efforts In Research and Production

type throughout the world. Aluminum alloys, which have been developed by a broad and consistent research policy, are being used by the majority of aeronautical engineers. Several alloys are available for specific purposes in all forms: Castings, forgings, extrusions, bar, sheet and tubes. Eighty to ninety per cent of the total structural weight of the modern high performance airplanes is aluminum alloys.

Great improvements have been made in manufacturing riveted joints and in the application of spot welding in order to reduce costs and obtain a super-smooth covering since skin friction and interference produce appreciable drag at speeds in excess of 250 m.p.h.

The Use of Magnesium

Magnesium alloys have not been employed to the same extent in this country as in Europe largely due to the availability of aluminum alloys, the lower corrosion resistance of magnesium, and the greater difficulties in fabrication. The strength-weight ratio of magnesium base materials in thin sections indicates no marked advantage and the lower hardness and modulus adversely affects the bearing strength at the joints. However, with the use of thicker sheets and of cast, extruded and forged members, the lower density material has the advantage. The extensive use of cast magnesium alloy wheels has demonstrated that magnesium castings are dependable under severe service. The chemical stability of these alloys in the presence of salt water has been greatly improved so that more extensive usage is assured.

Changes in Steel

Steel compositions have changed very little for several years. Three and one-half (3½) per cent nickel for utility and screw machine parts, and chrome-molybdenum steel for fittings and tubular structures are the standard types. Attempts to heat treat parts fabricated from these steels above an allowable stress of 200,000 lbs. per sq. in. have not been very successful, due to their inherent weakness under suddenly applied loads whenever the design requires abrupt changes in section. A less sensitive weldable steel which will permit an allowable design stress of 250,000 lbs. per sq. in. is one of the needs of the industry.

Arc welding has become a worthy competitor of oxy-acetylene welding for the fabrication of welded structures as the result of the improvement in electrodes.

Stainless Steel

The high tensile, corrosion-resistant steel containing 18 per cent chromium 8 per cent nickel has been used successfully in several airplane structures and a school of design is gradually being evolved which will take full advantage of its outstanding properties.

The nickel base alloys are pre-eminent where the combination of corrosion and heat resistance is required. The non-magnetic, heat-treatable alloys are replacing steels for certain critical parts.

Research

by John Johnston

According to such information as is available, the number of industrial research groups in the metallurgical industry increased by about 50 per cent between 1927 and 1938, and in these groups during this period the total research personnel more than doubled, the increase, both relative and absolute, being considerably greater in the ferrous than in the non-ferrous field.

This enhanced interest in systematic investigation of the many technical problems facing the metallurgical industry in its endeavor to meet the more and more exacting demands of the designing engineer, and indirectly of the public generally, is reflected in the much larger number of first-class papers published by American metallurgists now as compared to a decade ago, when METALS AND ALLOYS was started. The interpretation of many phenomena which then were obscure is being clarified and brought into a more philosophic system, and the newer views are being accepted so generally that we may even expect soon to see them incorporated in metallurgical text-books.

We have as yet taken only a few steps on the infinitely long road towards complete understanding, but we are surer of its immediate course and going faster, yet more safely, along it than ever before. There is a more widespread confidence in the efficacy of real knowledge, as opposed to hunches, in promoting the improvement of the metallurgical arts; and less attention is being paid to "explanations" in terms of words which themselves are vague and in need of explanation.

This is not to state that the behavior of a metal is not significantly affected by factors beyond our present means of apprehension, visual or otherwise; indeed it is more than likely that some of the present puzzles will not be solved until science succeeds in developing more powerful tools and more searching methods of investigation. Yet much remains to be achieved by proper interpretation of results obtainable by tools and methods now available in the careful hands of competent experimenters; and there are many reasons for faith that the next decade will bring forth a still better understanding of how best to win metals and to combine and shape them to fit each of the multifarious uses to which metal is put.

With the increase in number of men experienced in metallurgical research there is likely to be a larger number of significant papers, which may necessitate some modification of present methods of publication; and METALS AND ALLOYS before its twentieth birthday may face still greater difficulties in attempting to furnish its readers with a satisfactory map of the ground being gained in the battle against ignorance. There will continue to be differences of opinion so long as the evidence is insufficient to bring everyone to the same conclusion; but let us not take ourselves and our differences too seriously and remember that without such differences the metallurgist would be in a sort of Nirvana with little fun and, possibly, no job.

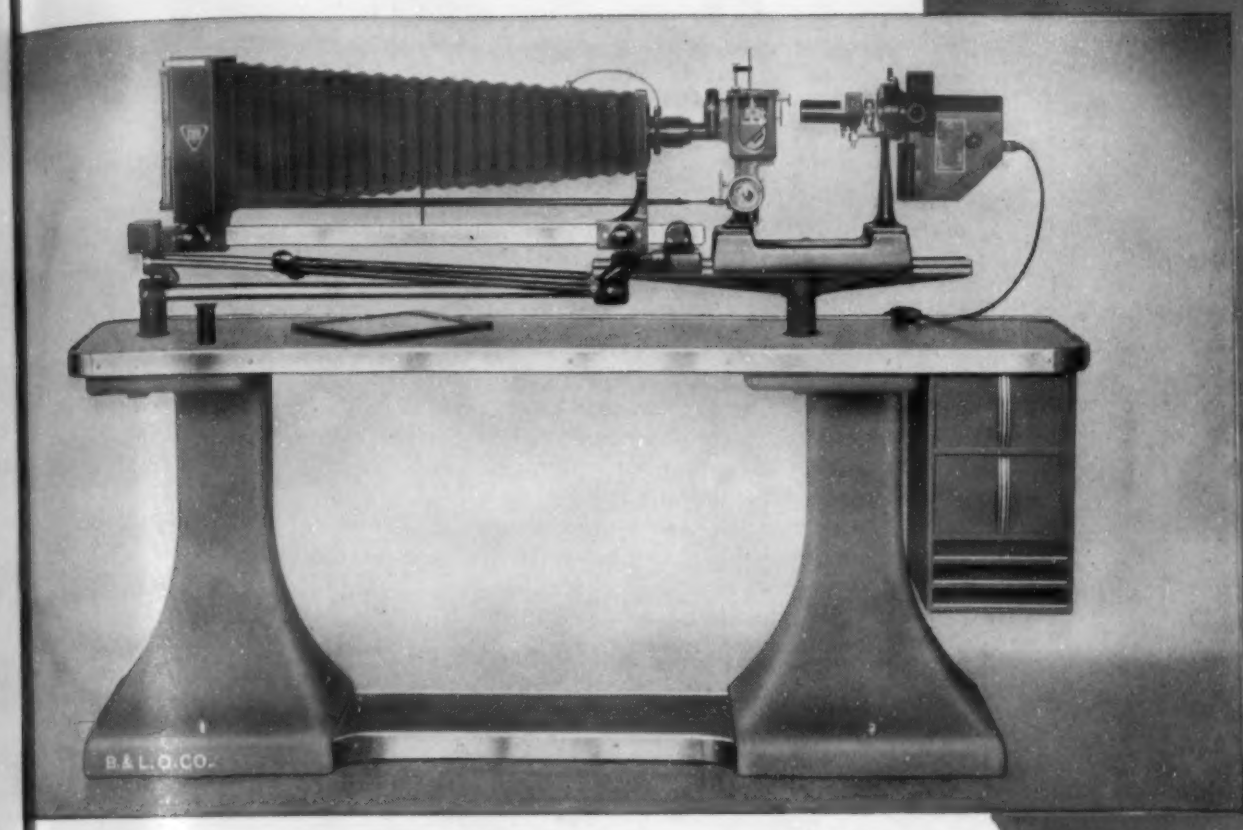
Gray Cast Iron



by James T. MacKenzie

The decade has been marked by development rather than by discovery in the gray iron industry.

Superheat

The discovery of the effects of superheat by Elliott and Piwowarsky in the previous decade has been assiduously followed up by a number of investigators with the result that we have a clear conception of the effects of superheating with quite a satisfactory hypothesis for these effects, i.e., the submicroscopic silicates, etc., but this is not universally accepted and work still continues. The discovery of germination or inoculation by Meehan in the early 20's has been followed by an enormous amount of research both technical and practical and has contributed greatly to our understanding of graphitization phenomena and control of structures.

BAUSCH & LOMB

FOR YOUR EYES, INSIST ON BAUSCH & LOMB EYEWEAR. MADE FROM BAUSCH & LOMB GLASS TO BAUSCH & LOMB HIGH STANDARDS OF PRECISION

The alloys—chromium, copper, molybdenum, nickel, titanium, and vanadium—have been studied both singly and in combination though, of course, not exhaustively since the combinations, especially considering the basic compositions available, are almost infinite. The general principles governing their application have been fairly well cleared up though much work remains to be done. The austenitic alloys, Ni Resist and the high chromium irons, have been developed for corrosion and heat resistance, and the martensitic alloy, Ni Hard, has proved remarkably successful for wear resistant service.

Heat Treatment

The principles of heat treatment have been the subject of much study and this includes the effect of section size, chill casting, nitriding, etc. Centrifugal casting, both on metal molds and sand molds, has been developed to a high state of efficiency for pipe, brake drums, cylinder liners, and other cylindrical hollow bodies. Although it was well on its way in the early 20's, centrifugal casting has really come into its own during these last 10 years.

The unique properties of cast iron due to the presence of graphite have been studied by a number of investigators. Notable has been the study of damping capacity, wear and corrosion resistance, machinability, freedom from galling and seizing, and insensitivity to notches, etc. This has developed into the cast iron camshaft and other automotive parts not thought of 10 years ago. Even crankshafts are now under test with excellent results.

Correlating Tests

The relation of tensile, compressive, torsion, and shear strength to transverse modulus of rupture has been correlated with the elastic and plastic behavior of the material which is due to the size, shape, and distribution of the graphite. The elaboration of the behavior of cast iron under combined tensile and bending stresses by Schlick at Iowa State College has resulted in the first rational method for the design of cast iron pipe.

Foundry practice, which is essentially the art of making a sound casting true to pattern, has been studied in detail. Sand control, gating and risering, facings, molding and coremaking have been studied and much work has been done to get the principles involved before the designing engineer. The electric furnace has contributed greatly to ease of production and to research. The cupola has been studied intensively and has been equipped with controls for blast volume, temperature, distribution, and humidity.

Technical Contributions

Notable has been the contribution of technical societies, institutes, and authors. The report of the Subcommittee on Impact of the American Society for Testing Materials; the two symposiums of the American Foundrymen's Association and the American Society for Testing Materials; the "Cast Metals Handbook" and "Alloy Cast Iron" of the American Foundrymen's Association; the work at Battelle Memorial Institute and the Bureau of Standards, at the Universities of Illinois, Michigan, Ohio State, Wisconsin, and Iowa State College, to mention only a few, are of outstanding importance in this country while abroad the British Cast Iron Research Association, the technical schools and institutes at Aachen, Düsseldorf, and Darmstadt have made most important contributions during the decade.

Several good books have appeared in addition to the society publications just noted: Moldenke's Second Edition of "Principles of Iron Founding" in 1930, Piwowarsky's "Hochwertiger Grauguss," Hurst's "Metallurgy of Cast Iron" and "Melting Iron in the Cupola," and Bolton's "Gray Cast Iron." The Alloys of Iron Committee have covered the alloy cast irons specifically, and the basic principles of cast iron generally, in their remarkable series of Monographs.

Welding

by C. A. McCune

The progress of welding is usually indicated by comparing the improved or existing applications with those of several years previous to the time the comparison is made. But today, thanks to the metallurgists, physicists and engineers of the United States of America, the new developments in steel production and the formerly unheard of steel fabricated articles, welding advance might well be compared to those of yesterday.

Within the past year many developments have been made in welding apparatus by both the gas and electric groups as well as improvements in materials by manufacturers of gas welding rods and electrodes all of which have contributed to what might well be considered the production of perfect welds at such low costs that fabrication by any other method would be prohibitive. On the other hand in any number of cases no other means than welding could possibly have been used.

A complete review of the accomplishments of welding from streamlined trains to electric refrigerators in the past year would cover a great deal more space than is permitted in this brief review but the following may be considered a cross section of outstanding industrial applications.

All Welded Ship

Probably one of the greatest advances during the past year, at least to some of the pioneers in the welding field, was the recent launching of the 18,500 ton all-welded oil tanker by the Sun Shipbuilding & Dry Dock Co. This vessel which is 521 ft. long, has a capacity of 6½ million gal., is one of three all-welded vessels built by the Sun company for the Atlantic Refining Co.

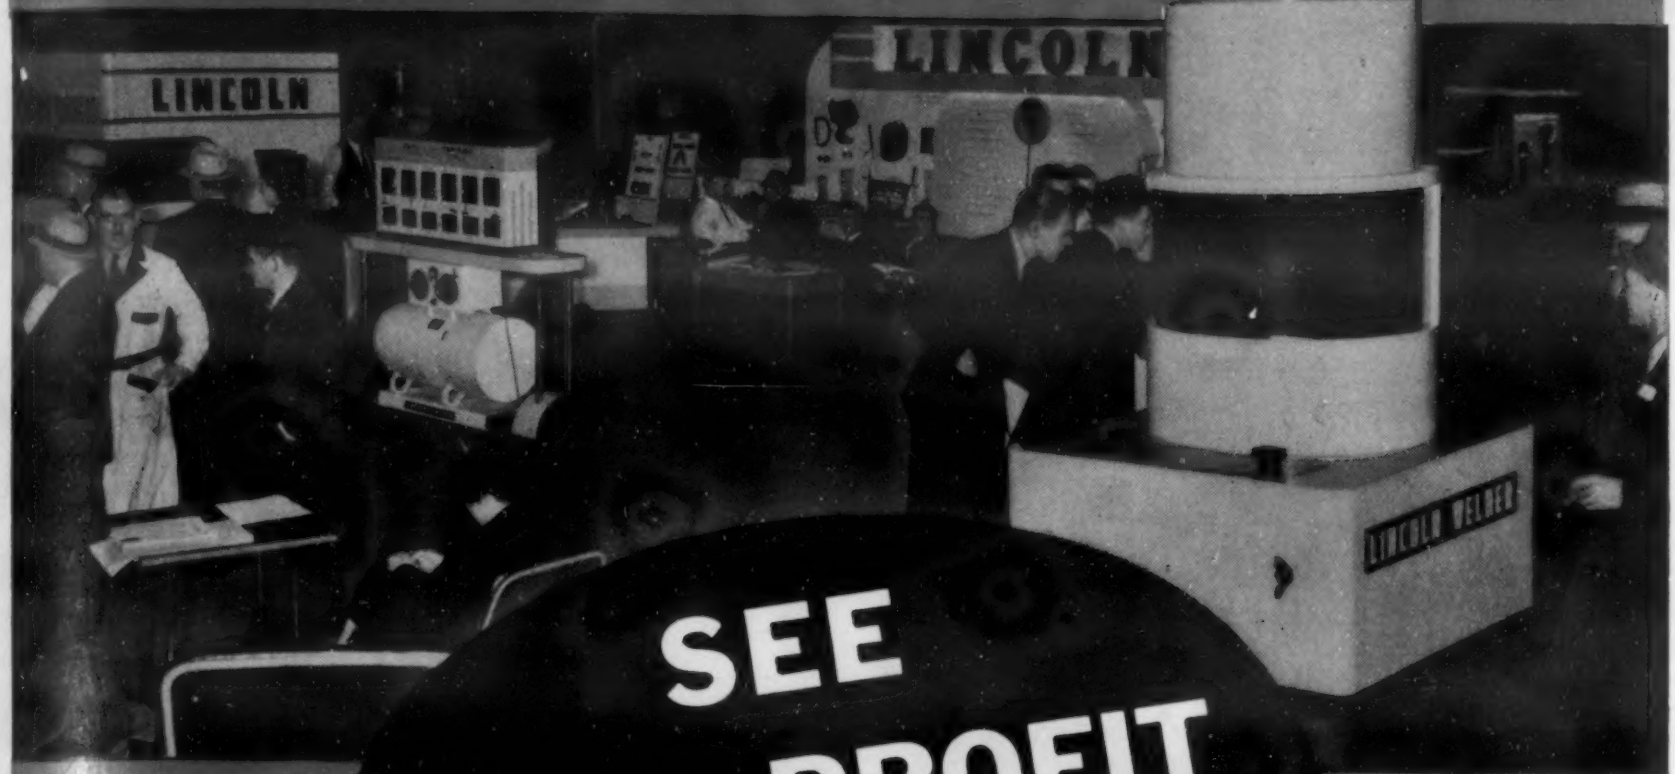
A considerable amount of research work was successfully carried out during the past year on cutting and temperizing of structural steels. Everyone knows of the advantages of gas cutting. In ordinary steels the heat effect due to gas cutting is generally negligible and in certain special steels preheating or flame softening is necessary. During the past year exact techniques have been developed particularly for steels used in the structural steel industry.

Flame hardening, while not new, is now being used in regular production work. Welderies are now accustomed to flame cut, arc weld and to flame harden special wearing parts as a regular routine procedure.

Welded Rails in Track

The potential possibilities of welding a main line railroad track are receiving important consideration. One estimate shows that the railroads can save as much as $100,000,000 a year by the elimination of track joint through welding. A considerable amount of research work in this field has been reported during the past year on rail joints welded by gas, arc, resistance and thermit. The results are decidedly in favor of welding.

The day is soon coming when one may go to the factory and pick out an all-welded pre-fabricated home ready to put on the site, in much the same fashion that he will buy his furniture. All that will be necessary is to connect up water, light and gas. This is not an idle dream. Actually such homes are now available, and welding has made possible their construction.



During the year the American Welding Society issued its tentative rules for fusion welding steam, oil or air piping in marine construction. With the general acceptance of this code it is expected that most of the pipe lines in new ship construction will be all welded.

A Welding Handbook

The American Welding Society issued its first Welding Hand-

When at the METAL SHOW—

Look into the latest in arc welding at the Lincoln exhibit. This giant model of the "Shield-Arc Jr." is one of the demonstration booths.

SEE how you PROFIT with LINCOLN EQUIPMENT

JOB SELECTOR and Current Control—both Self-Indicating and Continuous—of this New *"Shield-Arc Junior"* provide any TYPE of arc and any AMPERAGE for easy accurate setting. Assure top speed and quality on every job. In ratings of 75, 100, 150 and 200 amps.

GAS-START DIESEL is one of the latest Lincoln developments in engine driven *"Shield-Arc"* Welders. Small gasoline engine assures dependable starting in all kinds of weather. Diesel cuts fuel costs 33% to 66%.

BUILD-YOUR-OWN portable welder with this New 200-amp. *"Shield-Arc Junior"* for Coupled Drive. Equipped with Dual Continuous Control. Special heat-resistant insulation permits working at high average amperages for lower costs.

BRING YOUR WELDING PROBLEMS TO BOOTH H205

Don't miss seeing these new Lincoln developments in operation! And bring us your welding problems. Lincoln engineers and technicians, experienced in all phases of arc welding, will be at your service.

SELF PROTECTED—This New *"Shield-Arc"* Welder will not burn out! It is Self-Protected against overload, single-phase operation and all other burnout hazards. Permits use of large-sized electrodes for sustained operation at higher amperage for lower costs.

NEW ELECTRODES for a wide range of welding and hard-facing applications. Try them in our demonstration booth and see how they improve welding speed and quality.

IMPROVED SUPPLIES—Electrode holders, shields, protective clothing, cable and other accessories will be there for your inspection—to show you how they can cut your costs.

THE LINCOLN ELECTRIC COMPANY

Dept. LL-644, Cleveland, Ohio — **Largest Manufacturers of Arc Welding Equipment in the World**

book—a book of some 1200 pages written by more than 60 of the leading welding authorities of this country, and reviewed by some 257 other specialists. This represented the combined efforts of the leading welding talent of the United States.

A very considerable amount of progress has been made in the application of welding to oil well casing strings. Although the welded joint is not universally accepted as yet in this particular application, the greater percentage of casing strings is of the welded variety. A considerable amount of research work has been carried out in regard to the welding of low alloy steels used in the construction of such casing pipe. One of these strings 8100 ft. in depth was fabricated by the Carter Oil Co.

The first all-welded steel frame multi-story building was completed during the year under the New York City Building Code which now permits the use of welding.

Welding and Bridges

With the general acceptance of the AWS Code on Design, Construction and Repair of Highway and Railway Bridges, quite a number of bridges received a new lease on life. Some of these old bridges have been badly corroded, others not designed to carry modern trucks can be reinforced by welding to accomplish this. Welding permits repair or strengthening of these bridges at a minimum cost.

Non-destructive methods of weld inspection by the Magnaflux method and radiographic methods has become accepted practice for all important work.

The 13-story Woman's Hospital of Pittsburgh was erected in 58 noiseless working days; 100 tons of steel were required and the work was carried out less than 200 ft. away from the Eye and Ear Hospital and the Children's Hospital.

More and more the entire machinery and tool building industry is looking towards welding as a matter of economy and improvement of product. Welded steel in conjunction with welded castings is generally the accepted answer. Gas cutting plays a necessary and important part in this work.

The Automobile and Welding

Few of those who ride in automobiles appreciate that the modern car would cost twice as much and be of a much inferior construction were it not for welding; 3000 to 4000 welds are regularly made on a production basis in the modern automobile. High speed methods of production have been developed so that spot welds follow spot welds so quickly that the eye is unable to follow the movement.

Writing welding papers becomes big business particularly as, during the year, a leading electric company distributed some $200,000 in prizes for the best papers presented during the year. Several important power companies have installed all-welded high pressure power piping turbines operating with steam of 1250 lbs., at 950 deg. F. Several installations of this sort were recently completed by the Public Service Co. of Newark, N. J. Huge parts for the 200-in. telescope, the largest in the world, to be mounted at Mt. Palomar, Cal., was completed and sent on its way.

Welding in the construction of barges has practically become the standard method. Most of the modern barges are now constructed by welding instead of riveted or wood construction.

Welding in Diesel Engines

Importance of welding in the body construction of diesel electric locomotives and of the new streamlined trains is generally accepted. Quite a number were constructed during the past year using welding. Flame cutting assisted in the production of two steel plate fly wheels, the largest and heaviest made in steel plate. This required producing plate of 9⅛ in. thickness, weighing 56,215 lbs. Welding played an important part in the construction of the new steam electric locomotives produced by the General Electric Co. for the Union Pacific Railroad. Steam was generated by an all fire steam boiler of 1500 lbs. steam pressure and operates at 2500 kw.

Research

In depicting a year's progress in the welding field it is essential to refer to the enormous amount of research work along scientific and engineering lines being conducted by industry in the various laboratories, supplemented by the well-rounded program of research on a cooperative basis fostered by the A. W. S. This cooperative effort alone involves an expenditure of about $100,000 a year. On the various committees are serving 250 research workers comprising the leading scientific talent of this field in this country. Some 70 investigations are under way in the university laboratories. This is supplemented by coordinated programs in industrial and governmental laboratories.

Critical digests of the World's literature have been made and published on 35 selected topics. Each of these involves a review of some 500 articles written in several languages and scattered in many technical journals. Such investigations as the fatigue of welded joints at the University of Illinois are supplying the basic data for the design of structures subjected to dynamic stresses. Other investigations of an equally basic nature are being conducted by Massachusetts Institute of Technology, Ohio State University, Rensselaer and many others.

It is evident that the future of welding is definitely related to the future of steel and all other structural metals.

Metallurgical Education

by Robert F. Mehl

Metallurgical education has been in a period of unusually rapid development during the last 10 years. In an article as brief as this, one can only indicate the nature of this development and state those directions in which progress should be made in the future.

Educators are keenly aware of the responsibilities they bear to industry in the training of metallurgists. Limited to four years for converting a high school graduate into a metallurgical engineer, and having only the last two of these in which to provide the student with training in purely metallurgical subjects, the instructor can hope only to train men well in basic science and engineering. Whatever the time available, this is surely the proper principle, and fortunately the industrial metallurgist insists that he wants this primarily.

The Most Serious Problem

Possibly the most serious problem the educator faces is the scope of his subject. To provide a man with proper instruction in the basic sciences, to train him in engineering principles, to create in him an understanding of the very broad subjects of physical metallurgy and the physical chemistry of metallurgical reactions, and to lead him to see the application of this training to industrial work—which is the ultimate objective—is not easy within the limitations of the curriculum. A great economy of effort and a close correlation of widely diversified subject matter is required. It is exactly in this respect that great progress has been made in the last 10 years.

Where a generation ago a training chiefly in descriptive metallurgy was held adequate, now a metallurgical student receives a training in a far broader field: For example, his physical chemistry must be excellent if he is to use a modern approach to open-hearth problems, or if he is to understand problems in corrosion; his physics and mechanics must be good if he is to understand forming operations and the interpretation of tests of mechanical properties. The technical college is now providing the basic training necessary for such an extended metallurgical curriculum

Whitey Sez:

"It costs money to out-shout competition but you can out-class it almost at your own price."

PEEP IN THE MAURATH TENT (BOOTH B-123) AT CHICAGO'S METAL SHOW

MAURATH, INC., CLEVELAND

BUILDER OF BETTER WELDING ELECTRODES IN ALL ANALYSES

with, I think, gratifying results, judging from the experiences of recent graduates. The metallurgist today is given a better basic training and is given a much broader training than heretofore. The metallurgical educator is not an educational fadist; there is little evidence for lack of balance in the selection of curricula.

Importance of Graduate Work

Graduate work is of lesser importance, but it is of great importance none-the-less. With the growth of industrial research the demand for men with graduate training has far exceeded our capacity to supply. Many industrial laboratories have in past years employed men with advanced degrees in chemistry and physics for research work. I do not think this policy will nor should continue; properly staffed faculties in metallurgy can provide sufficiently basic training to develop men in whose hands future advances in the science of metallurgy in both its theoretical and practical aspects may be confidently left.

Generally speaking, I think it can be said that administrators in educational institutions are not aware of the potentialities in metallurgical education (I do not have C. I. T. in mind!); perhaps industry could be useful in pointing these out. Industry itself, I believe, could show a steadier interest in the efforts of metallurgical schools, for, though it is trite, is there a more important raw material for industry than the products of technical schools? With the extremely rapid increase in the demand for trained metallurgists, which shows no signs of abatement, the metallurgical profession as a whole should be concerned with the development of metallurgical education.

Copper and Its Alloys

by W. B. Price

The production of O.F.H.C. (oxygen-free high conductivity) copper probably constitutes the most noteworthy improvement in the commercially pure metal during the last 10 years. As is well known, this copper has greater ductility than ordinary tough pitch copper, and is practically immune to embrittlement by reducing gases, particularly hydrogen. It is especially useful in welding where reducing gases are usually present, as well as in applications involving subjection to reducing conditions.

Age-Hardenable Alloys

The widespread use of age-hardenable copper alloys has been retarded by the difficulties of manufacture, necessitating close metallurgical control. This is perhaps particularly true with copper beryllium alloys. However, there is a growing use of age hardenable copper alloys, especially in applications where properties not obtainable by non-aging alloys are essential.

Copper-chromium and alloys based on copper-chromium including additions of silicon, zinc, cadmium, silver, beryllium and zirconium because of high electrical conductivity as heat-treated have been widely used in resistance welding electrodes. A relatively new high strength-high conductivity alloy uses small additions of iron and phosphorus to copper. Very close compositional control is essential to obtain high conductivity which may be as much as 90 per cent that of pure copper. Copper-beryllium is used on a small scale, mostly for spring parts in electrical devices, non-sparking tools, and the like. Some of the copper-beryllium ternary alloys, using only a few tenths per cent of beryllium, show promise because of a good combination of mechanical and electrical properties. The copper-nickel-aluminum alloys, also age-hardenable, are being advocated for use where excellent mechanical, forming, and joining properties together with good corrosion resistance are necessary. One recommended use is for large hot-headed bolts. The nickel bronzes (copper-tin-nickel) have been widely publicized in recent years as an age-hardenable casting alloy of superior strength and corrosion resistance.

Non-Age Hardenable Alloys

In the field of non-age hardenable alloys, various silicon bronzes have come into wide use. Such alloys as Duronze, Everdur, Olympic bronze and Herculoy have been particularly in evidence. These materials have excellent forming properties, are corrosion resistant to a wide variety of media, and are more readily welded than pure copper. The catch phrase is "the corrosion resistance of copper with the strength of steel." Besides silicon, these alloys generally contain one or more of various metals, such as manganese, aluminum, zinc or tin.

The older plastic bronzes for bearings have been supplanted to some extent by binary copper-lead alloys with lead running as high as 45 per cent. These are used in heavy duty applications as a thin layer on a steel sheet. Chromium bronzes (copper-tin-chromium) have been suggested for roll neck bearings and similar heavy applications, but so far their use has been rather limited.

Free Cutting Alloys

With the present increased machining speeds, materials with very free cutting characteristics are desired. The well known leaded brasses may be supplanted in some measure by tellurium and selenium brasses. One advantage of these addition elements is the avoidance of a low melting constituent which interferes with hot forming.

The use of controlled atmospheres for heat-treating copper and its alloys promises to do away with much of the pickling used at present to clean the metal after annealing.

Production of longer coils of strip is being made possible by various methods including the use of larger cakes, continuous casting, and welding two or more coils together.

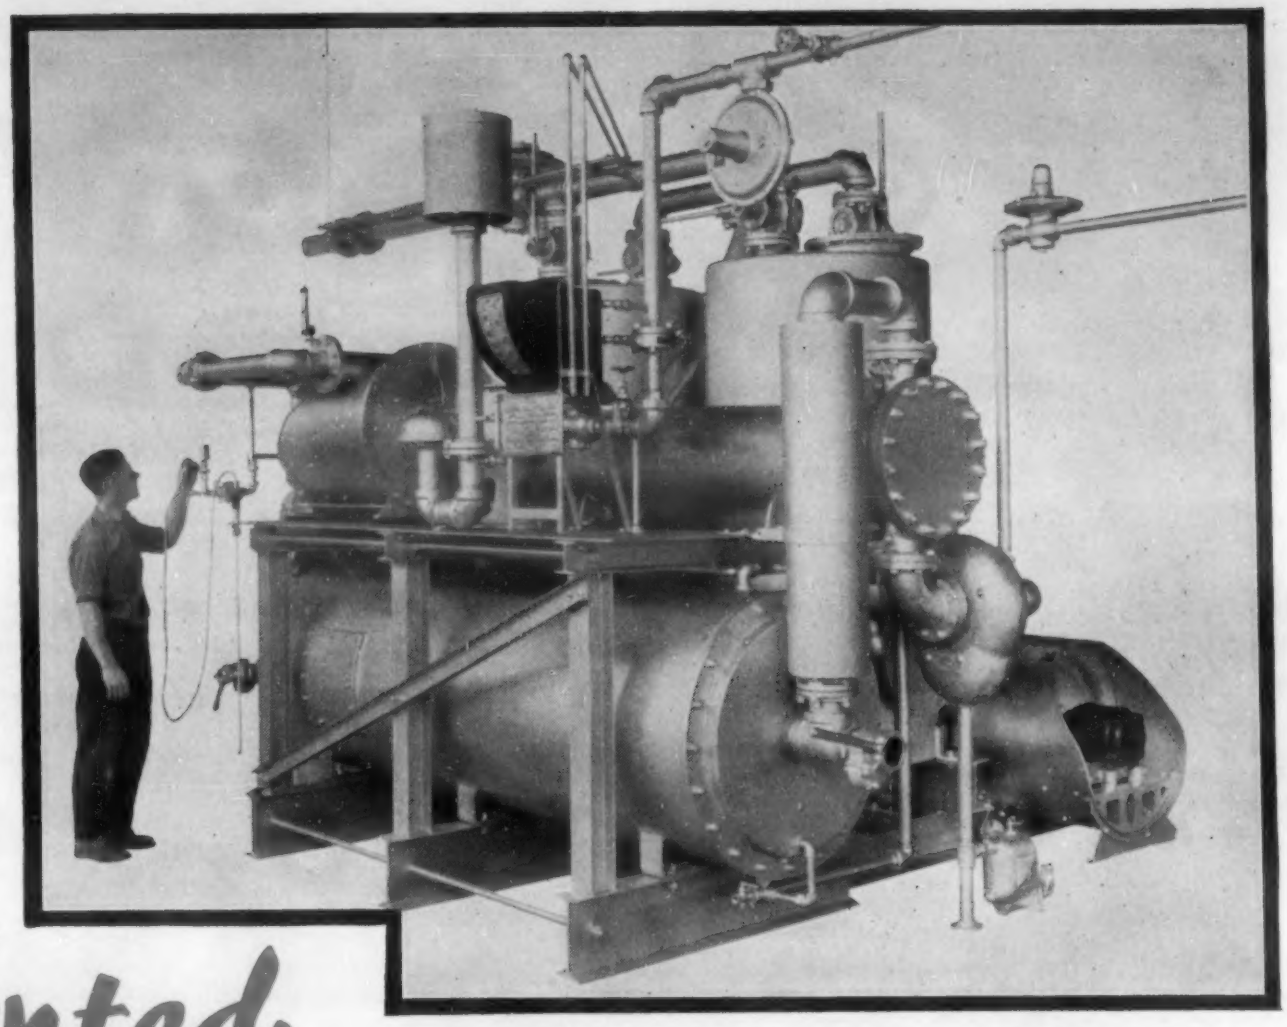
Open-Hearth Practice



by Leo F. Reinartz

There is no evidence that any fundamental changes will be made in open-hearth practice in the near future.

Three Major Developments

During the last year progress has been indicated by three interesting developments in the manufacture of steel by the open-hearth process:

1. A plastic chrome mixture has been rammed into the hearth of an open-hearth furnace and burned into a monolithic structure which, it is claimed is giving good results.
2. Several refractory companies have taken a leaf out of European furnace practice and have produced basic bricks for open-hearth furnace roofs. So far, at least 12 to 15 partial roof installations have been made. In most instances, sections along the front and back walls in the vulnerable parts of the roof have been installed. In the near future it is probable that some com-

Kemp 8,000 C. F. H. Atmos-Gas Producer with twinned, activated alumina towers.

Wanted: FUSSY CUSTOMERS!

We want to talk to the hair-splitters of the steel industry, men who can spot a blemish as far as they can see a stack of sheets . . because *we've got something* for them.

An imposing number of plants famous for rigid quality control are now using the Kemp Atmos-Gas Producer for bright annealing. But there are many more who will, once they have checked into the experience of present users and the three points of Kemp superiority:

1. Accurate proportioning of air and gas via the Kemp Industrial Carburetor.
2. Automatic continuous sampling by the Kemp Constant-Analysis Monitor which double checks and master-minds the Industrial Carburetor.
3. Complete desiccation (to the equivalent of a—40F dew point) with 100 percent availability through *activated alumina dryers.*

You'll want to know more, *much more,* about these Atmos-Gas Producers. Write, wire or phone **The C. M. Kemp Mfg. Co. at 405 East Oliver Street, Baltimore, Md., or Oliver Building, Pittsburgh, Pa.**

SEE OUR EXHIBIT

METAL CONGRESS
AND EXPOSITION

KEMP of BALTIMORE

pany will install a complete basic, suspended roof on a large open-hearth furnace. Added weight, radiation, hazard of spalling, and method of brick suspension are some of the problems that must be solved.

3. Temperature measurements in the bath of the open-hearth furnace are becoming more practical; at least two schemes are being used experimentally with good success.

Refractory companies are cooperating with operators to produce brick which can be installed in various parts of the open-hearth furnace system so that a campaign can be lengthened without serious intermediate costly repairs, and in order to prevent slowing up of the furnace towards the end of a campaign. In this development basic brick are used in front walls and on sloping back walls. Ports and furnace ends down to the floor level are lined inside with basic brick. This decreases wear and tear on ports, end walls, and decreases slag accumulations.

An unique slag pocket design has been tried which makes it possible to remove slag during the campaign of a furnace. This should help decrease deterioration and clogging up of checkers.

Insulation

Furnace insulation up to the charging floor level is standard practice in most open-hearth shops. Above the floor level the practice varies depending on the kind of steel made, skill of operators, economy of design, as well as type of fuel used.

In one open-hearth shop, a new principle of roof insulation is being tried out with promise of success. In another instance, a design, current in boiler practice for several years, has been adopted experimentally in open-hearth door and frame construction so as to reduce upkeep cost and save heat.

All these improvements, plus insulation, should decrease fuel consumption and increase hearth temperatures. If temperatures up to 3300 deg. F. can be reached, melting of scrap and pig iron will be speeded up and the overall efficiency of the furnace improved. By having excess heat available during the refining period, the open-hearth melter should improve the quality of the steel.

Automatic Control

Automatic control of furnaces has gained some adherents and lost others. It appears that the use of automatic draft control is increasing in popularity. Operators have had to be satisfied with some increase in furnace repair cost in order to secure other advantages connected with low draft practice, such as less metal oxidation and lower fuel consumption.

Many claims have been made for synthetic dolomites and magnesites. In general, the dolomitic compounds give relatively good results for "hot patching" and maintenance of furnace bottoms. Good results as bottom building materials have been reported for practically all the magnesites which various companies are placing on the market today.

Scrap prices are rising. There will be a tendency to increase the percentage of hot metal in shops where ore burden and blast furnace operating costs are low, and where burnt lime can be used without detriment to the quality of steel produced.

Metallurgical Progress

From a metallurgical standpoint, work continues actively on balanced charges, balanced slags, and close control of every open-hearth operation from the charging to the stripping operations. Throughout this development the key-stone to better quality has been the drive to improve uniformity in practice and raw materials. Progressive executives are looking ahead of the open-hearth department and are stressing uniformity in the production of "hot metal" in the blast furnace for open-hearth furnace use. Physically "hot" molten iron having the proper silicon analysis for the local conditions involved is a prerequisite for quality steel production.

More and more, metallurgical observers are becoming adjuncts and assets to the open-hearth superintendent in this drive for improved quality. Almost universally they report directly to the chief metallurgist.

Careful attention is being given to training the open-hearth organization in the rhythm of steady, regular charging, uniform speed of melting and refining, as well as reducing tapping and casting delays. These practices, in connection with uniform charges, and standardized refining technique, assist materially in producing steels which will meet the rigid specifications required by present-day metallurgical and physical needs of the trade.

Never before, has the word quality meant so much to the steel-maker. Never before, has he organized his operations so intelligently and enthusiastically as competition has forced him to do in recent months.

The open-hearth operator's slogan continues to be careful attention to the details of operations, continuous production, and uniformity of metallurgical practice from heat to heat.

Malleable Cast Iron

by H. A. Schwartz

Any industry lives only to the extent that its product fulfills adequately certain demands as to utility at a less cost than competitive materials. The malleable foundry is required to produce castings having certain minimal requirements as to strength, ductility, impact resistance, machinability and other physical properties, deliver them at the time required and at a price, for the finished article, which is less than that of the same article made of competitive materials. The relative importance of the various physical properties among themselves and in relation to delivery time and cost naturally vary with different applications.

Three Grades Recognized

Since the several requirements are not altogether compatible, it has been found necessary in the A.S.T.M. to recognize three grades of malleable differing in tensile strength and elongation. Some consumers, railways for example, regard high ductility and strength as the principal requirement and prefer grade 35018 of the A.S.T.M. specifications. Others, like the automotive industry, finding it impracticable for foundry reasons, to decrease their cross sections further to take advantage of higher strength, prefer the advantages of machinability and soundness accompanying the but slightly less ductile 32510 grade. The manufacturers of pipe fittings to whom soundness and machinability are of major importance have almost standardized on still weaker cupola malleable. All this is probably very good engineering judgment, for each obtains what to him are the most useful castings. This subdivision into a reasonable number of grades, each adapted to a specific purpose, is one of the most useful developments in the industry in the last decade.

Pearlitic Malleable

Recognizing instances where great strength is desirable, even at some sacrifice of ductility and machinability, the trade has developed a class of materials, somewhat illogically, called pearlitic malleable in which by virtue of heat treatment and/or alloy content the metallic matrix contains agraphitic ("combined") carbon. This is not always present as pearlite, as the name would seem to require, but may be martensite, granular cementite or anything between.

For these materials the A.S.T.M. has been able to develop only a descriptive form of specification which does not include any designation of properties. Since the materials have usually been developed each for a particular purpose, the possible combinations of properties found on the market are legion. It is an obvious advantage that this number should not be unduly restricted to the extent of depriving any user of a material which may be especially suited to his needs alone. The ability to vary these properties is an advantage to the malleable founder in getting and keeping business. It has been found relatively recently that the

THE OHIO CRANKSHAFT COMPANY

Cleveland, Ohio

graphitizing and other heat-treating methods of the malleable industry are applicable to alloys which should be classified as steels and a whole family of graphitizable steels seems likely to come into being.

Short Cycle Annealing

The relative importance of early delivery, and hence of a short annealing cycle, seems to be declining. It is a fallacy to assume that shortened cycles are necessarily economical. The heat required to keep a well insulated furnace at temperature is trivial compared with that to heat the charge. It is quite possible to operate perfectly orthodox ovens on an annealing cycle of around 90 hrs. An increased investment, per annual ton of capacity, may reduce this to say 70 hrs. by the use of tunnel type furnaces. Very highly specialized furnaces can reduce this time considerably more, but at much increased capital outlay. On economic grounds cycles faster than around 70 hrs. are difficult to justify. If cost could be sacrificed, furnaces could be built in which the heat transfer would be made very rapid and quite short cycles result. It is hard to find users who will pay more for the faster delivery.

A still further decrease of time could be accomplished by the adoption of special compositions of metal. Such practices are regarded as dangerous by many because they all verge closely upon metal which will not be graphite free as cast and occasional worthless material might result which would not be caught by inspection.

Conclusions

It may be well to point out in conclusion that the last decade has added little to the known metallurgical fundamentals but much to their commercial application. The improvements of equipment used by the founder have not here been touched on and would make another story.

Corrosion

by F. N. Speller

On the whole, much more has been accomplished towards a clearer understanding of corrosion processes and methods of prevention during the past decade than in the previous 10 years. It is now generally recognized that corrosion depends both on the metal and the environment in which it is placed, and is therefore controlled by a number of variables and includes a multitude of problems; that in the presence of water it is the result of electrochemical reactions at anodic and cathodic areas; that all metals (except some of the so-called noble metals) tend to corrode in certain environments; and that this tendency is retarded or prevented by interposing between the metal and its environment some kind of barrier against continued attack.

Much has been learned about metal surface films (and also paint layers) by laboratory research in which electrometric potential methods have played an important part.

Useful Life of Metals—Symposia

The useful life of metals has been increased by improving their resistance to attack, use of better protective coatings, and improved environmental conditioning.

Later developments in corrosion-resistant metals and alloys was well covered in a series of symposia in 1936, a comprehensive correlated abstract of which will be found in METALS AND ALLOYS, November and December, 1937 and January, 1938 ("A Correlated Abstract on Corrosion and Corrosion-Resistant Metals and Alloys") by V. V. Kendall.

Protective Coatings

More attention is being given to descaling and treatment with inhibitors (such as phosphoric acid mixtures) with thorough drying of the metal prior to painting (for example, flame descaling). Zinc chromate and other slightly soluble inhibitors are now generally used in the priming coat. There is a marked improvement in paints for both atmospheric and underwater service, due largely to the better synthetic materials used in vehicles and improved formulation.

Bituminous coatings for pipe and other underground structures are now more reliable. The interior of steel water pipe is now usually protected by the newer plasticized coal tar or blown asphalt enamels applied centrifugally while hot to a thickness of at least 1/16 in. Portland cement mixtures are still more durable and are also applied mechanically to the interior of pipe.

For protection against corrosive soil, these bituminous materials are usually reinforced with saturated asbestos fabric to a total thickness of about 1/8 in. Where necessary, soil stress is prevented by application of an outer shield. The corrosivity of soils can now be determined with a fair degree of accuracy (about 75%).

Anaerobic bacteria have been shown to be very destructive in certain clays and mucks containing sulphates and organic matter in absence of free oxygen. Oxygen is released from the sulphates by these organisms.

Cathodic Protection and Inhibitors

Cathodic protection was first applied to underground piping in 1928, and has proved to be reliable and economical. When coatings fail the piping system can often be kept in good operating condition by impressing a regulated current on the metal with considerable saving in maintenance cost. Improved appliances and technique have been developed for this purpose.

Application of neutralizers and inhibitors to industrial water and brine systems is finding increased use in protection of air conditioning equipment, heat exchangers, gasoline pipe lines, etc.

The use of a few parts per million of hexametaphosphate of soda (the so-called Threshold Treatment) reduces scale formation and promises to be useful in controlling corrosion in water systems.

The new (Langelier) analytical control of anti-corrosion treatment of domestic water supplies is finding useful application and is probably the first step towards further important developments by water works chemists and members of the A.S.T.M. Committee on Water for Industrial Uses.

Caustic Embrittlement and Colloids

The problem of caustic embrittlement has been greatly clarified, mainly due to the work sponsored by the Joint Research Committee on Boiler Feedwater Studies. Embrittlement is a type of corrosion fatigue caused by simultaneous action of chemical corrosion and high concentrations of dissolved solids in contact with highly stressed boiler metal. Careful workmanship and improved design of modern high pressure steam boilers have eliminated dangerous stress concentration and high concentration of dissolved solids (two of the three destructive factors), and new organic inhibitors are giving promising results in low pressure boilers of older design.

Certain colloids have been proved to protect stressed metal from corrosion fatigue, as in the mud fluid in rotary drilling of oil wells. The oil industry now have their corrosion investigations highly organized with respect to refinery, production, and transportation problems. Oil cargo tanker corrosion problems are not yet solved economically, but the work is well under way. Once-through condenser tubes are still subject to wasteful attack. More frequent and efficient cleaning should greatly lessen localized corrosion.

The American Coordinating Committee on Corrosion was organized this year to afford a clearing house for information and to facilitate useful contacts between investigators in this wide field. A classified directory of investigators and problems is now being prepared by this committee.

Vanadium

by Jerome Strauss

The importance of vanadium as one of the principal alloying elements of ferrous metallurgy is today as great or greater than it was at the beginning of the decade. Numerous changes have occurred in its applications, during these years, both in tool and in constructional steels, and these are briefly reviewed.

In High-Speed Steel

High speed tool steel (as distinct from air-hardening tool steel) began as a tungsten-chromium steel—that was in the early days of our century. Not long after its birth, the addition of a quarter per cent vanadium was tried and found to effect a marked improvement. By the time of the beginning of the World War, this amount had been increased until the standard composition averaged about 0.7 per cent. Higher contents had been tried and at least one brand contained close to 1 per cent carbon and 3 per cent vanadium. But all this was not too well understood—nevertheless in the most common composition (18 tungsten and 4 chromium) vanadium, and carbon, steadily increased until the former now averages about 1.1 per cent.

Recent studies have confirmed early experiences and, as fabricating technique improves, higher-carbon, higher-vanadium steels will appear in more widespread applications. Even now there is tonnage production of steels of 1 per cent or more carbon with 2 to 4 per cent vanadium. One may anticipate steels with still larger percentages with their greater cutting capacity and the consequent demand for sturdier machine tools.

In Low-Alloy and Carbon Tool Steels

In the carbon and low-alloy tool steels, the benefits of higher carbon and vanadium contents are being studied and appreciated. Especially noteworthy is the medium-carbon high-silicon, high-manganese steel containing 0.3 per cent vanadium or more and the approximately 1 per cent carbon steel with 0.45 per cent vanadium as its single alloying element. The former has been rendering, for close to these 10 years, exceptional service in both sharp and blunt tools subjected to extreme shock. The carbon-vanadium tool steel, a more recent development, is of interest due to affording the possibility of varying the depth of hardening over a wide range *without grain coarsening*—merely by adjustment of the time of heating and temperature used for quenching.

In Low-Alloy and Carbon Constructional Steels.

In the domain of constructional steels, it is perhaps not inappropriate to mention one type that remains unchanged. S.A.E. 6150 is still the pre-eminent spring steel where ease of manufacture and fabrication, plus the utmost in service, is demanded. Initial cost, only, restricts its applications, but this is secondary when service is severe and *overall cost per unit of performance* is the yardstick.

Among newcomers in the constructional field, the manganese-vanadium type is the most important. In the very low carbon ranges (about 0.2 per cent and less) it is important for its high useful strength and exceptional welding qualities. In higher ranges of carbon (up to 0.4 per cent) an unusual combination of high yield point and high ductility (and impact strength) is secured, after normalizing and tempering, quite equal to those obtainable in many other alloy steels only by quenching and tempering. These manganese-vanadium compositions are all characterized by exceptionally high endurance ratios. In both castings and forgings, these compositions have found widespread use.

Nitriding steels, aluminum-free and therefore free of the defects often encountered in steels of high aluminum content, are of the chromium-molybdenum-vanadium type. With 2 to 5 per cent chromium or more, ½ per cent molybdenum and ¼ per cent vanadium or more, a range of desirable properties is secured that is well suited to many applications of this hard-surfacing method. This type is equally usable in castings and in forgings.

Small Amounts of V

The contribution of vanadium in very small amounts (about 0.1 per cent or less) to the transverse properties of heavy forgings has grown so rapidly in the last decade that its employment for this purpose is now almost universal. Extension of the field of the very low vanadium steels is continuing (this is quite apart from such use in carbon tool steels) and may be confidently expected to make great strides in the very immediate future. As this is being written, a number of constructional steels with vanadium contents less than 0.05 per cent have been made which, though fine-grained, possess exceptional hardening capacity and have unusual toughness at high values of hardness. They promise to open up new metallurgical vistas.

From Some Leading Metallurgical Engineers

Hard Carbides

by Zay Jeffries
Chairman, Carboloy Co., Inc., Cleveland

Of the total production of cemented carbides since their introduction in the late twenties, more than 95 per cent has been in the past decade. Prior to 1929, tungsten carbide with a cobalt binder was used exclusively. The applications were mainly for wire-drawing dies and cutting tools for cast iron and non-ferrous metals.

Variety and Application

Now the industry is rich, not only in the variety and number of grades of carbide, but also in the variety and number of applications. While tantalum and titanium carbides, intimately mixed with tungsten carbide, are now used for many purposes, the tungsten carbide grades greatly predominate. Cobalt is still the principal binder—in general, the more cobalt the tougher and softer the product. Grain size control has been superimposed on composition to secure properties not otherwise obtainable. Processes have been developed to commercialize the manufacture of large pieces and parts of unusual shape. The techniques of brazing tips to steel shanks and mounting die nibs in steel casings have been markedly improved. The improvement in grinders and in tool grinding has been revolutionary.

One greatly expanded use is for wear and corrosion-resistant parts. This field includes, among others, nozzles, guides, valve stems and seats, meter fingers and pawls, and chilling plates for hardening and tempering thin stock. One machine having 25,000 wearing-part pieces now runs for weeks without attention, whereas formerly changes were required three times daily.

An interesting new product, used for grinding-wheel dressers, small grinding wheels, glass laps, core bits, etc., is made by imbedding diamond fragments in cemented tungsten carbide.

Influence on Other Industries

Year by year, the cemented carbide industry is having a more important influence on other industries. The abrasives manufacturers have developed wheels especially to grind the carbides. Certain of these contain crushed diamond. Machine tool builders have developed lathes and milling and boring machines with high speeds, increased power and improved means for chip removal. In some instances the new machines are designed to use only cemented carbide tools.

New and improved alloys have been commercialized because they could be successfully machined for the first time by cemented carbide. Among these are certain aluminum-silicon alloys and hard, fine-grained irons from a high steel charge. The use of machined parts made from difficultly machineable non-metallic materials has also been expanded.

A number of innovations in shop practice have resulted from the use of cemented carbide broaches. Some of these would be impractical with the older tool materials. Also, the carbides are used extensively for facing the wear surfaces of a large variety of gages. These include ordinary, as well as master, gages. The increased life is sometimes more than a hundred-fold.

Dies

The use of cemented carbide wire-drawing dies has become practically universal. There is constant extension of use to the larger dies, both round and shaped, for bar stock. The finish is excellent and the product can be held to close dimensional tolerances. Cemented carbide dies and mandrels are also used extensively for drawing seamless tubing.

Cemented carbide dies have been developed for shaping sheet metal in presses. Until recently, this application has been confined to relatively small dies, but now large dies are coming into use.

During the last few years the use of carbides for machining steel has substantially increased. Grades containing either tantalum or titanium carbide, or both, added to tungsten carbide, are especially suitable for steel-cutting.

Notwithstanding the marked strides made in quality, price reductions have been drastic. At the beginning of the decade the price was around $1.00 per gram, and now a sliding scale of prices ranges down to $0.113 per gram in quantities.

These high spots of a decade of progress but poorly reflect the significance to society of cemented carbides. Each modern automobile, truck, bus or airplane bears the imprint of cemented carbide in its manufacture. Telegraphic messages are sent more reliably and economically because cemented carbide contacts are used. It has even found its way into the home as a part of the grinding member in a kitchen waste disposal unit. Every time we use a modern telephone, or listen to the radio, or turn on an electric light, it is a practical certainty that cemented carbide has played a part in the manufacture of some of the equipment involved.

The Future

But even greater things are in store for the next decade. Cemented carbide is the hardest and most wear-resistant metallic substance available for tools, dies and machine parts. The trend is toward its judicious use to strengthen the weaker links in the chains of industrial devices. The new techniques, improved grades, greater adaptability to varied uses, and the lower prices, all tend to accelerate this movement.

Low-Alloy, High Strength Steels

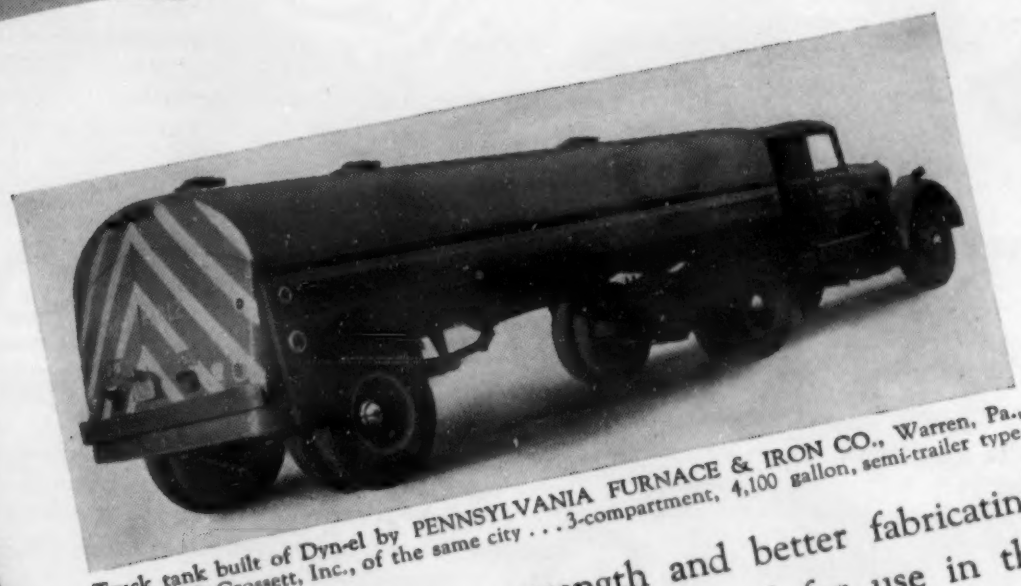
by B. D. Saklatwalla
Partner, Saklatwalla & Foote, Pittsburgh

The past decade has witnessed significant advances in the steel industry, when viewed from the standpoint of applied research. Gratifying results have been due largely to a growing realization, on the part of scientists and metallurgists, of the commercial advantages to be gained by placing superior materials in the hands of designing engineers, and then cooperating closely with them to assure their satisfactory application. The immediate future affords great possibilities for the further development of steel alloys to meet the increasing demands of an ever-changing industrial civilization. Research of this character, if it may be so termed, backed by proper experimental engineering and sales development, is a certain and profitable means of increasing the tempo of business. Considering the highly competitive situation existing in the steel industry itself, and the real, and constantly growing, competition of the aluminum and magnesium alloys, plastics, etc., these new objectives of steel's technicians have appeared none too soon. They constitute the one logical and promising basis for building broader markets and re-establishing profit margins.

The development of low-alloy, high strength steels is a clear example of the tangible results to be derived from such purposeful research. Engineers generally, and transportation engineers in particular, now realize that ordinary carbon open-hearth steel performs its functions only at the expense of unnecessary dead weight, when compared with the superior steels of today. Low resistance to corrosion and abrasion were factors in excess weight. In most cases, therefore, carbon steel could not be used in a manner that took full advantage of its strength properties. The new materials should prove a boon to the railroads. With almost every avenue to lower operating costs closed to them by one restriction piled upon another, weight reduction and modernization of equipment loom up as hopeful directions in which to look for economy.

Carbon and Low-Alloy Steels Compared

The problem of providing proper materials for wholesale weight reduction in many branches of industry was not one relating to mechanical strength alone. It proved complex indeed when the need for an integration of several properties in a single steel was found essential to the purpose—strength; resistance to impact, corrosion and abrasion; ease of forming; satisfactory welding, without, in general, the necessity of stress relieving; adequacy for use in the as-rolled condition, without heat treatment; and, on top of all, low cost. Failing a satisfactory score on these counts, the objectives sought in the lightened structures could not be obtained. It was requisite that they should give a service life at least equal to that of the former, and heavier, structures of carbon steel, with initial and maintenance costs no greater; otherwise the full benefits of the lower operating costs striven for, could not be realized.



It was a big order, but, with a full knowledge of the requirements, a painstaking metallurgical research proceeded systematically with the creation, development, and commercial promotion of the low-alloy, high strength steels. These new materials have benefited all concerned—to the steel maker more profitable and wider markets; to the consumer greater efficiency and operating economy without sacrifice of a single advantage previously enjoyed.

Corrosion

Following the greatly increased use of steel as a structural material since the turn of the century, it was inevitable that enormous losses, due to corrosion, should become apparent. In the development of superior open-hearth tonnage steel—which these new steels are in reality—the need for added resistance to corrosion was a prime consideration. Accordingly, the combination of alloys selected to provide strength was such as to materially increase corrosion resistance. The older high tensile group did not possess this important property, and therefore the reduction of section could be accomplished to a limited extent only. Their forming properties, weldability, and, in general, abrasion resistance, were also inadequate.

The new steels may be fabricated by customary processes, and with the existing equipment commonly found in the plants of fabricators. They possess their strength properties in the as-rolled condition without heat treatment, and ordinarily do not require preheating or stress relieving for welding purposes. They are produced by the ordinary open-hearth process and are available at a cost per pound which is only somewhat higher than that of carbon steel and not out of line considering their superior

. . . and the Tank is 900 Lbs. Lighter

Truck tank built of Dyn-el by PENNSYLVANIA FURNACE & IRON CO., Warren, Pa., for Wm. F. Crossett, Inc., of the same city . . . 3-compartment, 4,100 gallon, semi-trailer type.

Because of its greater strength and better fabricating properties, "A. W." Dyn-el is selected for use in the construction of this new type of truck tank . . . Built of hot rolled carbon steel, this 4,100 gallon tank, including manholes, piping, emergency valves, catwalk, hose tubes, trim skirting and under framing, weighs 5,200 pounds. Built of "A. W." Dyn-el, it weighs only 4,320 pounds—a saving in hauling costs of 900 pounds on the tank alone... and this lighter tank is actually stronger than the heavier job and has greater resistance to shock, fatigue and corrosion.

The 48-page book, "A. W." Presents Dyn-el, gives full details of savings in weight and cost possible with this new high-strength, flat-rolled steel. Diagrams, tables and charts cover a wide range of tests and properties. To executives, this book gives a quick picture of performance and costs. To engineers, it gives complete fabricating and design properties and table of sizes and weights. We will be pleased to send you a copy.

utility. Thus, structures may be built of them, due to the fewer pounds required, at a cost practically the same, or, in some instances, only slightly higher than that of similar structures constructed of carbon steel. All things considered, the properties of these steels are nicely proportioned to the desired results.

The superior low-alloy corrosion resistant steels are found either in the chrome-copper, or the nickel-copper groups. The chrome-copper group, originated in this country in 1922, has been developed to the present improved commercial grade with addition of silicon and phosphorus. The nickel-copper group appeared somewhat later. In England and on the Continent of Europe, chrome-copper steels have been used widely since about 1928, and seem to be the predominating type at present. The guiding factor in effecting a choice from either of these two main groups should be the actual performance shown for a number of years in the particular service required. This is especially true in evaluating their relative corrosion resistance. The life of any equipment is governed so definitely by the functions required of it that service history, unfortunate though it seems, appears to be the only reliable criterion.

In Transportation and Bridges

The low-alloy steels have gained prominence by their wide use in railroad transportation, where the immediate need for them proved greatest. Many service applications have been made, however, in other fields. The shipping industry has problems which parallel those of the railroad industry, closely, and their solution will be found in the adoption of the new steels. Weight reduction and corrosion resistance in static structures are also proving economical. In Europe the use of chrome-copper steel in the construction of a number of large bridges and transmission towers for electric power lines is particularly notable, and the percentage of weight reduction is most impressive. The Madagascar suspension bridge and the bridge over the Zambesi River, both in Africa; the Howrah-Calcutta bridge in India; the Chien Tang-River bridge in China; the Malarsee bridge in Sweden; the Ardeche to Teil viaduct and the Troy-Paris and Eguzon-LaCellette power lines in France, are examples of chrome-copper structures well worth detailed study. In special cases where transportation constitutes a substantial cost factor, the weight-saving possibilities of the new steels determine their use. For instance, the largest skyscraper in the East, located in Shanghai, and approximately 80 meters in height, was built of chrome-copper steel, fabricated in Germany, and shipped to China.

An "Engineering Eye-Opener"

Thus, the introduction of the "low alloy, high strength steels" has not merely added a few new products to the numerous existing types of so-called "high tensile steels"; it constitutes an important engineering development introducing large possibilities and new conceptions in engineering design. As aptly put by one prominent designer, they have been an "engineering eye-opener," not only awakening a consciousness of corrosion losses and of dead weight, but also providing the solution for these problems.

The broadening of their application, and further improvement in their uniformity and manufacture, should prove a powerful stimulus to future engineering and metallurgical progress. A sorely needed expansion in the steel demand of America, and indeed of the world, can be achieved through such new developments—those of a nature that will accelerate obsolescence and hasten the retirement of existing equipment and methods. In most cases the lower operating costs which may be realized through modern design, based upon the new materials available today, will force the replacement of old structures with those of the more efficient, hence more economical, type.

Chromium

by J. H. Critchett

Vice President, Electro Metallurgical Co., New York

The past decade has seen the greatest growth in the metallurgical use of chromium of any period in the history of the metal. Rapid commercialization of the stainless steels has of course been the outstanding reason. In the meantime, usage of chromium in structural and engineering steels, moderately corrosion-resistant steels, cast iron, and non-ferrous alloys has steadily increased.

Low-Alloy Chromium Steels

The development of low alloy, high strength structural steels for use in equipment requiring superior strength, corrosion resistance, and weldability is outstanding. Chromium is a basic ingredient which imparts strength and, together with copper or phosphorus, or both, imparts corrosion resistance to such familiar steels as "Cor-Ten," "Ductiloy," "Mayari R," and "Cromansil," among others.

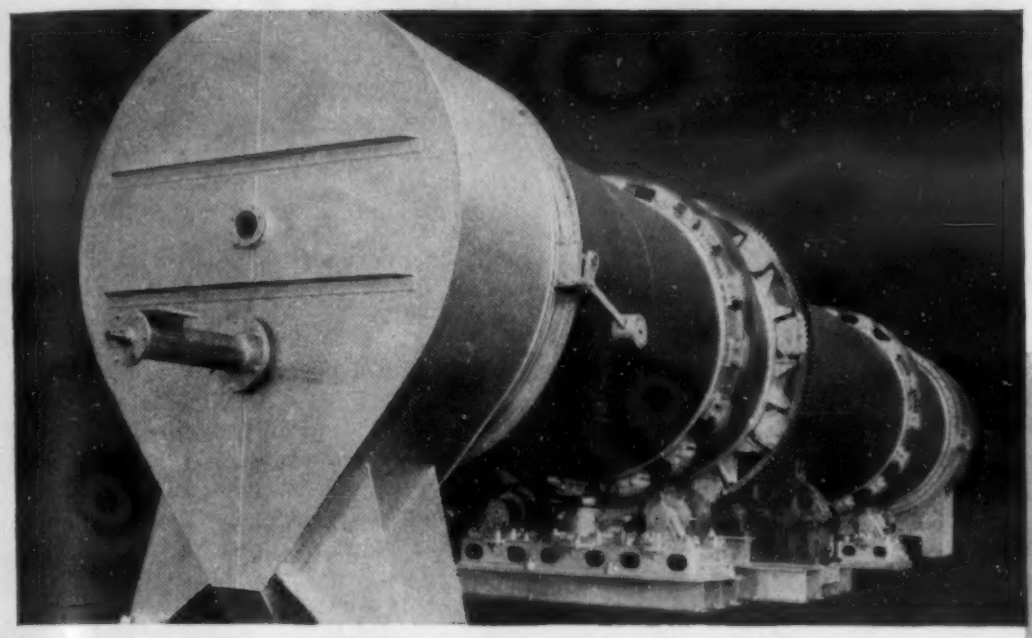
In addition to increased use of the 1 per cent chromium, heat-treated engineering steels, a steel containing 3 per cent chromium, often with molybdenum, now accounts for some of the expanding use of chromium. This steel has high wear resistance and that combination of toughness and strength necessary for cylinder liners, crank shafts, and similar machine parts. Abroad it is being used in many high duty airplane engines.

Steels with 4 to 6 per cent chromium, generally with 0.50 per cent molybdenum, are used for cracking or handling hot oil and superheated steam. Corrosion resistance of these steels, taken in conjunction with their economics, dictates their choice even though this corrosion resistance is not of the same order of magnitude as that of stainless steels.

In Cast Iron

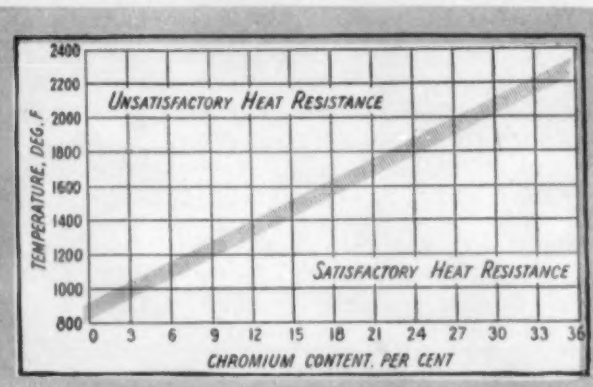
In the development of the modern cast irons, chromium has found a leading place. Additions are made either as alloy to the ladle or through briquets melted with the charge in the cupola. Even such a small amount as 0.25 per cent Cr begins to stabilize the structure of the iron, whereas increasing amounts, up to 1 per cent or more, raise the strength without unduly affecting machinability, increase the wear resistance, and very markedly reduce the tendency of irons to grow on repeated heating and cooling. Still greater percentages, while noticeably increasing the brittleness of the iron, so improve resistance to oxidation that they find wide use in parts of furnaces, automatic stokers, and similar applications.

Among the non-ferrous uses of chromium, the increased use and improved performance of nickel-chromium electrical resistance wires in both home appliances and industrial furnaces are notable. Recently an iron base resistance wire, containing about 35 per cent of chromium with 8 per cent of aluminum, has come on the market. It is finding its place in industrial furnaces run at high temperatures, such as those used for heat treating high-speed steels. Likewise, the advent of Inconel, a 15 per cent chromium, high nickel alloy, and the efficacy of chromium in high conductivity, high strength copper alloys point to increasing usage in the non-ferrous field.



In Stainless Steels

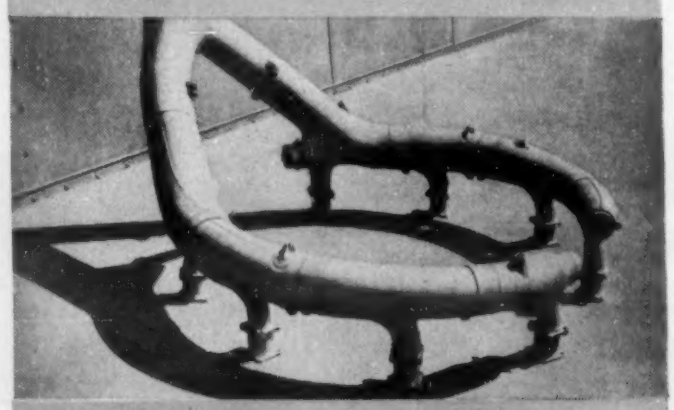
The rapid and continuous growth of stainless steel in the last 10 years, often in opposition to the trend for general steel production, is most striking. Basically, stainless steels derive their "stainlessness" from the 12 per cent or more of chromium which they contain. During the decade knowledge of the properties has increased the application of these steels, and better technique in manufacture has resulted in markedly improved quality. Modification of older analyses has been a further important factor.



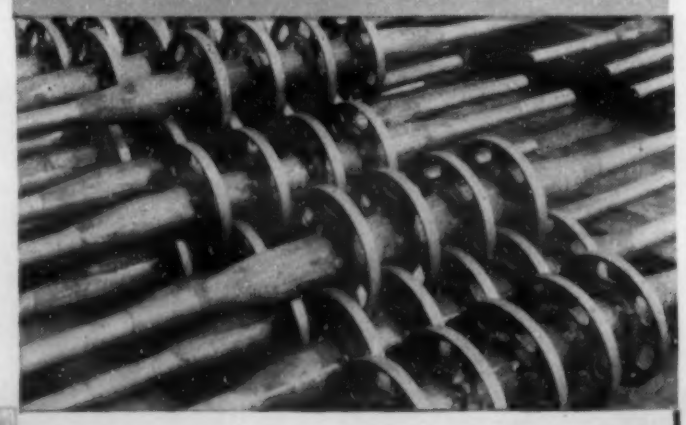
For example, stainless cutlery steel now carries higher chromium and carbon, with or without molybdenum, for improved edge-holding properties. Stainless engineering steels, especially those designed for the more exacting uses, carry 16 to 18 instead of 12 to 14 per cent chromium. Addition of a little nickel to a 16 per cent chromium steel makes it respond to heat treatment so

ON HOT JOBS . . .

Chromium Safeguards Equipment Investment



This giant rotary kiln is fabricated from 27,800 pounds of 25-12 chromium-nickel steel to resist the heat of high-temperature processes. The curve below shows the relationship between chromium content and temperature, based on chromium steels found satisfactory in service.



CHROMIUM-ALLOYED iron and steel can stave off the oxidation that blasts equipment investments where high temperatures are encountered. Chromium iron stoker links can wade continuously through raging furnace temperatures and remain in satisfactory condition many times longer than iron without chromium. In roasting kilns, it is chromium steels that last against the effects of searing temperatures. Vital performance of aircraft engines is safeguarded by chromium steel exhaust valves and manifolds where the flaming heat of burned gases would make short work of ordinary steel. Even in the inferno of annealing furnaces, high-chromium steels give long service.

We do not make iron or steel—but if you do—or if you fabricate or use equipment subject to high temperatures or other conditions where ordinary steels will not serve—"Electromet" offers without obligation unbiased metallurgical data and assistance in solving your alloy problems.

The chromium content of the steel used in the aircraft collector ring above and the pack heating furnace shafts below makes them resist the extremely high temperatures encountered in service.

At the Show—You can learn more about chromium and how it imparts heat resistance and other valuable properties to iron and steel at the Electromet exhibit, Area L305, National Metal Exposition, International Amphitheatre, Chicago, October 23-27, 1939. Plan now to attend and bring your questions.

The word "Electromet" is a registered trade-mark of Electro Metallurgical Company.

that it becomes particularly useful in airplane struts. Oxidation resistant steels of 20 to 30 per cent chromium are toughened by the use of nitrogen. Each of these improvements has resulted in better over-all economy.

"18 and 8"

The most popular of the stainless steels is the austenitic 18 per cent Cr-8 per cent Ni variety. In the past decade many important modifications have been made to permit steels of this category to meet more severe conditions. The increase of alloy content to 25 per cent chromium and 12 per cent nickel is typical. The addition of titanium or columbium to maintain ductility and corrosion resistance after the steel is subjected to elevated temperatures is another important development. Increasing hot workability by higher manganese, and increasing corrosion resistance, particularly the pitting and contact type, by the addition of molybdenum are further illustrative and account in no small part for the constantly growing use of the austenitic stainless steels.

The combination of corrosion resistance, very high strength and ductility, and weldability of cold rolled austenitic stainless steels has made possible the modern light-weight structures typified by the stainless steel trains and truck bodies, where decrease in weight produces revenue.

With continually wider use, knowledge of the valuable properties of stainless steels becomes spread and the demand thereby increased, so that it is safe to look ahead to their continued rapid growth for a number of years to come.

Molybdenum

by A. J. Herzig

Chief Metallurgist, Climax Molybdenum Co.

Nothing can give a better idea of the progress of molybdenum as an alloying element for iron and steel during the past 10 years than a comparison of the world consumption figures for 1929 and 1938. In 1929 the world consumption was about 3,000,000 lbs. as compared to a consumption of about 28,000,000 lbs. in 1938. These figures are particularly illuminating in view of the fact that world steel production was 118,300,000 gross tons in 1929 and about 105,850,000 gross tons in 1938.

The situation in certain industries offers interesting side lights on the progress of molybdenum steels. For example, in 1929 there were only three recognized SAE types. Today, there are four, comprising 13 individual steels. Also, in 1929 only a few automobile manufacturers were using molybdenum steels at all. All major automobile manufacturers are now standardized on molybdenum steels for a number of highly stressed parts, and one uses them wherever alloy steels are required.

In the Oil Industry

The use of molybdenum steels for oil drilling equipment has increased from practically nothing in 1929 to an almost universal use today. A combination demand for stronger materials and better drilling economy in deep drilling has led to the use of molybdenum steels of various types in practically every kind of drilling and pumping equipment.

The same extension in use has taken place in oil refining. In 1929 little was known about the creep strength of steel at elevated temperatures, and there was less necessity for the knowledge. Continual increase in operating temperatures and pressures made good creep properties essential and led to the development of several molybdenum steels particularly adapted to refinery work. Today these steels are standard. Much the same situation has resulted in the standardization of carbon-molybdenum steel for steam generating equipment.

In Stainless and High-Speed Steels

The period between 1929 and 1939 has already seen considerable progress in the addition of molybdenum to the stainless, or corrosion-resisting steels of the "18 and 8" variety.

High-speed steels containing molybdenum first appeared in 1932. Since then much work has been done in the molybdenum-tungsten grade in developing improved types, and several are now available. Molybdenum in amounts up to 1 per cent is also being added to standard tungsten high speed steels.

Molybdenum steels have become widely adopted in aircraft construction during the past decade. Chromium-molybdenum steel (SAE X4130) is practically standard for certain structural members and parts. Molybdenum nitriding steels and various SAE molybdenum steels are extensively used for engine parts.

Much the same situation with regard to molybdenum steels exists in many other industries. The steels have become thoroughly established for a great number of applications in the last 10 years. It is particularly worth noting that these "newer" steels are replacing steels that were formerly firmly established with a coincidental saving in cost and improvement in quality.

In Cast Iron

As to cast iron, molybdenum cast iron was practically nonexistent in 1929. In fact that is just about the period of the first intensive experimental work on molybdenum irons. To sum up what has been done in the ten year period, today the production of molybdenum irons of tensile strengths between 60,000 and 80,000 lbs. per sq. in. is perfectly practical. A great deal of progress has also been made in the development of molybdenum irons having high strength in heavy sections. Thanks to these developments the field for molybdenum irons has extended to include many varieties of industrial equipment.

The work of investigating the fundamental effects of molybdenum on ferrous alloys has paralleled the progress in application. To take only one instance, the study of the effect of molybdenum on the transformation rate of steel has produced data of decidedly practical interest to users of steel.

Nickel and Its Alloys

by Thos. H. Wickenden

Assistant Manager, Devel. and Res. Div., International Nickel Co., Inc., New York

The first article in the first issue of METALS AND ALLOYS—except for the editor's introductory remarks—was entitled: "Two Decades of Precipitation Hardening Alloys," by Zay Jeffries. The past decade has seen the principles involved extended to many alloy combinations and among these the nickel-containing alloys have played a prominent part indeed, extending over a wide range of nickel contents from the nickel-tin age-hardening bronze to the age-hardening of nickel itself by the addition of such elements as titanium or beryllium, and in the intermediate ranges of nickel and copper we find small quantities of silicon and aluminum—either separately or together—utilized to promote this strengthening and hardening effect.

High Nickel Alloys

A number of new and interesting high nickel-containing alloys, generally with chromium and/or molybdenum, have been developed in the heat and corrosion-resistance field but the alloys of 10 years ago—with some refinements—constitute the bulk of material used in commercial applications today. The electrical resistance alloys are a typical example where the basic compositions remain the same but by refinement in manufacture and deoxidation their service life has been increased on the order of four or five fold; minute additions of calcium, cerium, thorium, zirconium and aluminum have contributed to this improvement. New information on high temperature properties of cast and

wrought heat-resisting alloys together with better engineering utilization of these data have contributed much to their advancement and widening field of use. The thermostatic alloys have extended their range of usefulness and have enjoyed a broad expansion in diversified fields.

Metallic Nickel and Nickel Plating

Wrought and cast metallic nickel is much more widely used today than was the case a decade ago, being used in a variety of applications and industries. While the use of nickel was well established at the beginning of the period for coinage purposes, the number of governments adopting it has increased at least 50 per cent and the type of coins placed in circulation has doubled. The acceptance of nickel coinage by the South American countries has been quite pronounced. In the construction of tubes for radio, X-ray, cathode ray and various electronic applications nickel is being used in substantial quantities for plates, grids, screens, cathodes, etc. The chemical industry accounts for the largest tonnage use, in many cases as commercially pure nickel tubes, plates and shapes, but the introduction of nickel-clad steel during this period has stimulated its use in the construction of equipment of various kinds—the caustic industry being one of the principal users but also finding application in the rayon industry and the manufacture of synthetic resins and plastics. Important developments in welding technique, welding rods and coatings for nickel and its various alloys have been a big factor in its growth, as equipment in contact with corrosive material can be made to present continuous corrosion-resistant surfaces.

In the nickel plating field far reaching developments have taken place. The commercial acceptance of bright nickel plate has been outstanding; less spectacular but of great importance has been the increasing demand for heavier nickel plate not only in parts exposed to atmospheric corrosion which are generally finished by a flash of chromium, but in some heat and corrosion resisting applications and in the rebuilding of under-sized parts—the latter has been stimulated by recently published information on heavy deposits and hard nickel plating. A recent development may extend the use of nickel plate much further for application under mild and intermediate corrosive conditions. In the process the nickel plated surface is reported to have an impervious coat with remarkable resistance to salt spray and other corrosive conditions.

Powdered nickel has become readily available during this period and is rapidly finding many uses in powdered metallurgy. It is being used in paints both for its decorative effect as well as its corrosion resistance; also a nickel ink is available for printing.

While high permeability nickel-iron alloys have increased in use, the outstanding development in the magnetic field has been the introduction of the aluminum-nickel-cobalt type of permanent magnets which have such high magnetic strength and permanence that they are finding wide application in radio speakers, high tension magnetos, watt-hour meters, direct current instruments, and in small and medium size motors. In addition, these magnets are being used in magnetic chucks, magnetic separators, and magnetic filters for removal of iron particles from lubricating oil. While most of the alloy is produced by casting, the technique of manufacturing by pressing and heating metal powders has been commercially introduced which permits the making of small and accurately shaped permanent magnets.

The use of nickel in brass, bronze and nickel silver has shown noticeable expansion, extending from the use of small quantities in red brass to refine the grain and improve its pressure-tightness, to the increased use of nickel-silver in architecture, for plumbing and decorative purposes. The wide acceptance of 70/30 copper-nickel alloys for handling salt water—an old alloy but new information on its resistance to sea water corrosion and non-fouling characteristics, being toxic to marine growth—has led to its wide acceptance for salt water lines and condenser tubes, not only on ships but in refineries and chemical plants.

Continuous Hot Strip and Plate Mills

by G. G. Beard
United Engineering & Foundry Co., Pittsburgh

Within the last 10 years there have been many outstanding developments in the fabrication of various steel products. Among the various advances made, the development in the art of rolling flat steel products by the continuous and semi-continuous processes is outstanding.

Actually the continuous strip mill was a development of a continuous sheet mill first installed by the American Rolling Mill Co. at its Ashland, Ky., plant in 1924, which was followed by the installation of a semi-continuous strip mill at the same company's plant at Butler, Pa., in 1926. However, it was not until the period 1929 to 1939 that a rapid increase in the number of such units took place due to increasing demands for sheet and strip steel products. The location of these continuous strip mills in the United States has, with a few exceptions, been confined to certain districts close to points of consumption and the products of those mills have been dictated to a large extent by the demands of local industries, as for example the automobile industry, which naturally favors the installation of such high-capacity single purpose mills.

During the period from Jan. 1, 1929, to date, the following mills have been installed in the United States:

Company	Width of Mill	Year Placed in Operation
Carnegie-Illinois Steel Corp.:		
Gary, Ind.	38-in. Continuous	1929
So. Chicago, Ind.	96-in. Continuous	1931
Youngstown, Ohio	43-in. Continuous	1935
Gary, Ind.	80-in. Continuous	1936
Homestead, Pa.	100-in. Semi-continuous	1937
Fairfield, Ala.	48-in. Semi-continuous	1937
Clairton, Pa.	80-in. Continuous	1938
Allegheny-Ludlum Steel Co., Brackenridge, Pa.	36-in. Continuous	1932
American Rolling Mill Co., Middletown, Ohio	80-in. Continuous	1929
Bethlehem Steel Corp., Lackawanna, N. Y.	79-in. Continuous	1935
Sparrows Point, Md.	56-in. Continuous	1937
Ford Motor Co., Dearborn, Mich.	66-in. Continuous	1935
Granite City Steel Co., Granite City, Ill	90-in. Semi-continuous	1937
Inland Steel Co., Indiana Harbor, Ind.	79-in. Continuous	1932
Indiana Harbor, Ind.	46-in. Continuous	1938
Jones & Laughlin Steel Corp., Pittsburgh	96-in. Continuous	1936
National Steel Corp., Ecorse, Mich.	38-in. Continuous	1930
Ecorse, Mich.	96-in. Continuous	1936
Otis Steel Co., Cleveland	77-in. Continuous	1932
Republic Steel Corp., Cleveland	98-in. Continuous	1937
Sharon Steel Corp., Sharon, Pa.	24-in. Continuous	1932
Wheeling Steel Corp., Steubenville, Ohio	60-in. Continuous	1929
Youngstown Sheet & Tube Co., Youngstown, Ohio	79-in. Continuous	1935

The following figures illustrate the total annual capacity in gross tons of all continuous and semi-continuous hot strip and plate mills in the United States as of December of each year for the past ten years:

Year	Annual Capacity in Gross Tons
1929	4,214,000
1930	4,749,000
1931	5,469,000
1932	7,069,000
1933	7,069,000
1934	7,069,000
1935	9,310,000
1936	11,510,000
1937	14,504,000
1938	15,644,000
1939 (August)	15,644,000

From the above figures, the period of inactivity between 1932 and 1935 will be noted, due to the adverse economic conditions existing at that time. It is also interesting to note that in the three-year period from January, 1935, to December, 1937, the capacity of hot strip and plate mills was doubled.

Due to the fact that the leading steel corporations are now in general well equipped for the present and probable future demand for flat rolled steel products, we cannot look to any appreciable increase in strip mill equipment within the next 10-year period comparable with the outstanding increase which has taken place within the past decade.

So far as the mills themselves are concerned progress in their construction has been marked by an increase in mill speeds with corresponding increase in motive power, heavier construction and the utilization of more and more auxiliary equipment for the production of a better product.

Metals and Alloys at High Temperatures

by N. L. Mochel
Metallurgical Engineer, Westinghouse Electric and Mfg. Co.

It is quite impossible to review in the space of a few hundred words that which has taken place during the past 10 years in the application of metals and alloys at high temperatures. The term "high temperature" is a relative one. A comparatively small increase in temperature above the normal introduces the same high temperature considerations in the application of some metals and alloys as does the increase of many hundreds of degrees in the application of others. High temperature considerations vary widely in different applications and industries. Characteristics important to one mean little to another. One may require information as to creep rates for one application one-one-hundredth or one-one-thousandth as great as for another. One may be interested in some cases in a life of 20 or more years; others a life of a few months. Total deformation is a vital consideration in some cases; in others it is relatively unimportant. This widely varying nature of the high temperature problem has been more and more appreciated in recent years. With this has come the realization that much available high temperature data is of doubtful value to some industries, although quite usable to others.

Early Symposiums

In this country, sufficient interest had been aroused by 1924 as to justify a symposium, jointly sponsored by the American Society for Testing Materials and the American Society of Mechanical Engineers. As a result the Joint Research Committee on Effect of Temperature on the Properties of Metals was formed the next year, and this Committee has taken the leading part in the years since that time in the field indicated by its name. A more or less periodic taking stock of what we have, what we need, where are we going, is very necessary in most fields of activity. Early in the 10-year period under review, in 1931, it was considered desirable to hold a second symposium, to thoroughly consider the needs of the various industries, and to take stock of available materials and data.

To meet a growing cry for creep data, the Committee collected all available test data on the subject, both in this country and abroad, and this collection of data, 848 pages in all, was published in 1938. Despite the 848 pages, this publication indirectly showed how very poor we are as regards reliable data on many materials in active use.

The Creep Test

Despite the many objections to its use, despite the expense and time and difficulties involved in carrying out reliable creep tests, this test continues to be one of the most important considerations in the application of metals at high temperatures. Methods of test are still considered as tentative. The Howe Memorial Lecture of the A.I.M.E. in 1939, by Gillett, under the title "Some Things We Don't Know About the Creep of Metals" is a timely and constructive discussion that all interested in creep should carefully study.

A growing interest on the part of those primarily interested in applied mechanics and in physics has been and will continue to be of great help in the interpretation and use of creep data.

Creep Not the Only Consideration

The 10-year period has developed a better appreciation of the fact that creep is not the only high temperature consideration. Mat-

Consult E F ENGINEERS

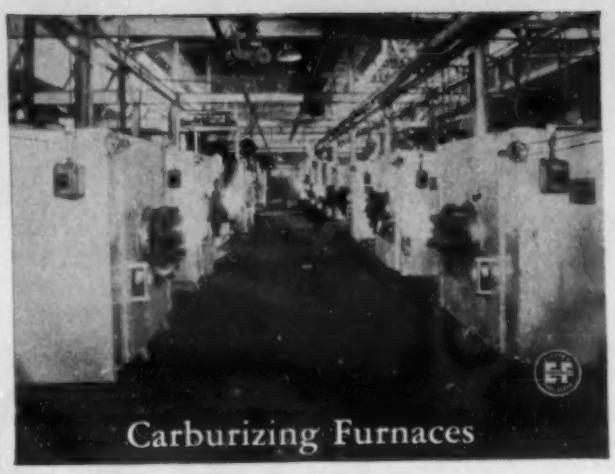
FOR WAYS TO:

- Improve the quality of your heat treating.
- Increase your furnace production capacity.
- Reduce the cost of your heat treating operations.

Whether it's a case of hardening, normalizing, brazing, annealing, carburizing, enameling, heating for forging or any other heating or heat treating process, E. F. engineers offer you a wealth of experience. They have applied electric, gas or oil-fired furnaces to practically every conceivable industrial heat treating need.

With both electric and fuel divisions, E. F. engineers are in a position to make a thorough and impartial analysis of your problem and recommend the best type for the particular job.

E. F. equipment is marked by certain refinements in design and ruggedness of construction which combine to assure greater efficiency and flexibility of operation, coupled with long-term operating economy.



If you are considering additional furnace equipment or any changes or improvements in your present equipment permit us to study your problem. We will show you just what you may expect from E. F. furnaces in the way of improved quality, increased production and lower operating costs.

ters of relaxation, combined stresses, stability, fatigue, embrittlement, and many others must receive equal consideration in many applications.

As stated before, creep tests are expensive, and require much time and they are difficult to carry out properly. There has been much seeking for a "shorter route to India," and as is usual in such cases, some new discoveries have been made. The work of White and Clark in their time-to-rupture tests is one such case, and better appreciation of the value of the relaxation test is another. There will be much further thought along these lines, the comparison of results from various shorter tests with those of the long-time creep tests. There will be several further considerations of fatigue at high temperatures.

Manufacturing Variables

The work of the Joint Research Committee on the effect of manufacturing variables on creep resistance certainly may be considered as the most important forward step in the 10-year period. The work has largely been carried out at Battelle. It is by no means finished, but it has already explained the wide differences in creep characteristics reported for supposedly similar steels. It has brought the realization that the creep test is perhaps the most sensitive test that we have yet applied to materials. It has definitely shown that analysis alone cannot guarantee desired creep properties, that variables of deoxidation practice, heat treatment, grain size, and alloy content all have a bearing on the behavior at high temperatures. This work is vitally important in the next item of this review.

The American Society for Testing Materials, especially through its Committee A-1 on Steel, as well as through A-10 on Iron-Chromium, Iron-Chromium-Nickel and Related Alloys and B-4 on Electrical-Heating, Electrical-Resistance and Electric-Furnace Alloys, has proceeded steadily on its way in the development of standards for materials for high temperature service. Standards for castings, forgings, pipe, tubing, plates for boilers, nuts, bolting, have already made their appearance. The work of the Joint Research Committee on manufacturing variables will permit of further improvements in these standards.

Non-Ferrous Materials

The need for better information on the effect of temperatures on non-ferrous materials has arisen and the Joint Research Committee is now "taking stock" in this field. Non-ferrous materials offer many advantages, such as corrosion resistance and thermal conductivity in many applications, but we appear to be very poor in our knowledge of their high temperature properties. The non-ferrous field will produce interesting and valuable information and materials in the future; as a matter of fact several comparatively new high nickel alloys show promise of better load-carrying ability at low red heats than available steels.

Metals and Alloys at Low Temperatures

by Francis B. Foley

Director of Research, The Midvale Company

The principal problem involved in the application of metals to service at sub-atmospheric temperatures is one of toughness. This is the opposite of the problem involved in elevated temperature service where, as a rule, the ductility of metals increases, flow sets in and strength becomes the matter of principal concern.

There are many instances in elevated temperature application of metals where ductility is low, metal breaks short without warning and both strength and ductility have to be studied. There are, however, no cases on record where metals subjected to low temperatures under stress have decreased in strength although ductility, particularly in ferrous alloys, is frequently lowered to the danger point. In the case of many non-ferrous metals, particularly the nickel and the copper base alloys, not only does strength increase with decrease in temperature but ductility, as measured by elongation in tension or by notched bar impact tests, is found also to increase.

In view of these general facts the study of the effect of sub-atmospheric temperature exposure on the properties of metals has centered in the convenient notched bar impact test.

Non-Ferrous Metals and Alloys

Charpy impact tests made on 45-deg. V-notched specimens of pure nickel show an increase in impact value from 135 ft. lbs at room temperature to 236 ft. lbs. at minus 112 deg. F. and 227 ft. lbs. at minus 310 deg. F. Cold drawing or annealing has little effect on these values. Monel metal, 69 per cent Ni-29 per cent Cu, when hot rolled, is only slightly affected by refrigeration, having a value of 219 ft. lbs. at normal temperature and 196 at minus 310 deg. F. Annealed Monel has about the same values as hot rolled metal but cold drawing lowers them somewhat to 161 ft. lbs. at room temperature falling off to possibly 122 ft. lbs. at minus 310 deg. The addition of 13 per cent Cr, 7 per cent Fe and some carbon to produce the alloy known as Inconel produces a metal having impact values about like those of Monel but cold drawing lowers the toughness of Inconel considerably to values of 33 or 40 ft. lbs. at room temperature and 28 to 33 ft. lbs. at minus 310 deg.

Pure copper behaves like pure nickel when tested at sub-atmospheric temperatures in that its strength increases at low temperatures and at the same time its ductility also increases, sometimes markedly. Pure copper, with a tensile strength at room temperature of 31,400 lbs. per sq. in., has a tensile of 58,000 lbs. at minus 292 deg. F. corresponding Izod values being 43 and 50 ft. lbs. Cupro-nickel, nickel-silver, 70-30 brass, manganese bronze, aluminum bronze, quenched copper-beryllium and Cu-Ni-Al alloys all maintain their toughness down to minus 292 deg. F. Aged copper-beryllium has a low Izod value, 2 ft. lbs., at room temperature with a tensile strength of 186,600 lbs. per sq. in. and gives 3 ft. lbs. at minus 292 deg. F. with a tensile strength of 214,000 lbs. per sq. in. The Cu-Ni-Al alloy has a tensile of 90,900 lbs. per sq. in. at room temperature with an Izod value of 40 ft. lbs. which is increased to 107,000 lbs. per sq. in. at minus 292 deg. F. with an Izod value of 55 ft. lbs.

Ferrous Metals and Alloys

Ferrous metals present a different picture. When iron is sufficiently alloyed to produce homogeneous stable austenite, it maintains good impact values down to liquid air temperatures and below. For example, when nickel of over 42 per cent is alloyed with iron, impact values are high at all sub-atmospheric temperatures at which tests have been run. A 60 per cent Ni-Fe alloy has a Charpy impact value at normal temperature of 47 ft. lbs. which increases to 61 ft. lbs at minus 300 deg. F. Austenitic 18 Cr-8 Ni had a Charpy value of 56 ft. lbs. at room temperature and 47 ft. lbs. when its temperature was reduced to minus 300 deg. F.

Low alloy steels and carbon steels present more of a problem than any of the metals so far mentioned. These ferritic steels, to differentiate them from the austenitic steels, are rendered tough at sub-atmospheric temperatures only by controlling the alloy content and by proper treatment. Tests of such steels show certain trends. Carbon seems to be detrimental to good low temperature toughness. Nickel and copper, which in the pure state have good toughness at very low temperatures, appear to be good alloying elements when added in proper amounts for preserving the toughness of ferritic steels at low temperatures. Manganese, molybdenum and vanadium, when added in proper amounts, appear also to aid in preserving the toughness of steels. Under ordinary circumstances ferritic steels can rarely be made to show very good toughness at temperatures much below minus 150 deg. F. but they can be made to show good toughness at that temperature. Ordinarily they have quite low values at liquid air temperatures.

MO-MAX
TRADE MARK REG. U.S. PAT. OFF.
MOLYBDENUM-TUNGSTEN
HIGH SPEED STEEL
For data, write The Cleveland Twist Drill Co., Cleveland, Ohio

A steel of low carbon with 3 per cent Ni and 0.25 per cent Mo has found considerable favor for use at temperatures down to minus 150 deg. F. With a double normalizing and drawn at 1200 deg. F., it will have a Charpy value of 25 to 35 ft. lbs. at this temperature. In castings it has quite as good values as in forgings.

The factors conducive to toughness in steels at low temperatures appear to be: Low C content, proper alloy content, structural homogeneity and freedom from internal stresses. Some alloys appear to act as specific tougheners while other alloys appear to aid in producing necessary refinement of structure. Treatments which produce the finest and most homogeneous microstructure together with freedom from internal strain are essential requirements.

Endurance Limit Under Repeated Stress

by H. F. Moore
University of Illinois, Urbana, Ill.

The last 10 years study of the mechanism of "fatigue" of metals, especially by the aid of X-ray diffraction, has shown that under repeated stress there is a process of "fragmentation" in crystalline grains which does not necessarily mean a destructive spreading crack. At some unknown stage this fragmentation may start an actual fatigue crack. The slip planes on which fatigue cracks start, are found to be definite atomic planes within a crystal. Studies of effect of size of crystalline grains have indicated some advantage in small grains, but the amount is quite uncertain. Much more data has become available on the fatigue strength in non-ferrous metals.

Effect of Stress Raisers

The quantitative study of the effect of stress raisers has made considerable progress. The use of transparent models viewed by polarized light to determine the theoretical stress at a given stress raiser has come into wide use, and the "plaster model" method has also been used. It has been found, that, owing to the slight inelastic strains which can be developed even in the brittlest of our metals, "peak" stresses are reduced, and actual stress concentration is not as severe as theory calls for, and so far it has always been less severe than the stress concentration indicated by the photoelastic or the plaster model methods. In general, high strength steels are always more sensitive to stress raisers than low strength steels, thereby partially reducing their advantage.

Little has been done on the sensitivity of non-ferrous metals to stress raisers. The fatigue strength of large specimens of some metals has been found to be distinctly less than that of small specimens. It has been found that surface conditions, stress raisers and size play so important a part in determining the strength of structural parts and machined members that the endurance limit determined from small polished specimens is not very reliable as a guide for design. Full-size tests of machine and structural parts are becoming more and more important. Such tests have been made on pressure vessels, railroad rails, bolts, car axles, structural joints, welded and riveted, and wire.

The structural engineer has become "fatigue minded." He has realized that in many parts, especially of a rigidly welded or riveted structure, there are repeated secondary stresses and while these secondary stresses may not be important under static conditions, under repeated loads they may start cracks, and the structural engineers have taken up studies of welds and riveted joints. For many structural parts the number of cycles of stress during a satisfactory "life" is measured by thousands rather than by millions, and the determination of endurance limit for a relatively small number of cycles is satisfactory.

Corrosion Fatigue

Study of corrosion-fatigue has continued to demonstrate the serious damage done by this phenomenon and a considerable study of chemical inhibitors and protective coatings has been made. The question of the combined effect of corrosion-fatigue and stress raisers has been studied and it has been found that the additive effect of these combined actions varies widely in different metals.

From the viewpoint of our studies of stresses, strains and strength, the development of fatigue of metals has forced us to recognize that our common formulas are not rigidly true when applied to actual metals. They may be regarded as a very close "statistical" approximation when *ma*croscopic volumes of metal are involved. However, when we consider resistance to repeated stress a *mi*croscopic volume may be the nucleus of a spreading crack. At present we meet this situation by using our ordinary formulas and photoelastic or other mechanical determination of localized stress, and then modify the results by empirical "notch-sensitivity" factors for different metals.

HERE'S YOUR MACHINE!

This machine will be exhibited in our Booth No. J-325 National Metal Show.

Features

OF THE OLSEN L-TYPE HYDRAULIC TESTING MACHINE:

1. **20,000 TO 60,000 LB. CAPACITY.** Overall height, 63½". Floor space, 10 sq ft. Approximate net weight, 2,000 lbs.
2. **INDICATING GAUGES IN INSTRUMENT PANEL.** Isolated from loading cylinder.
3. **CYLINDER IN BASE.** Lowers center of gravity.
4. **CONSTANT SPEED, GEAR-TYPE PUMP.** Quiet and efficient. No pulsation.
5. **DIRECT FLEXIBLE COUPLING CONNECTION OF MOTOR TO PUMP.** Eliminates noise and drive slippage.
6. **PUSH BUTTON STARTERS.** Standard equipment.
7. **FOUR COLUMN RODS.** Makes sturdy construction.
8. **CROSSHEAD ADJUSTING CRANK.** Easy to reach.
9. **STURDY OIL RESERVOIR.** Bolted to base directly under pump.
10. **SEPARATE CONTROLS FOR LOADING AND UNLOADING.**

THE OLSEN L-TYPE HYDRAULIC TESTING MACHINE . . . for Foundries, Vocational Schools, Small Colleges, Welding and Specialty Shops! Wherever funds for testing work are limited, this machine provides performance of highest efficiency. It is designed, engineered and built to Tinius Olsen standards throughout . . . and those are standards which have been foremost in the field for 59 years! Built for extreme compactness, it permits fast, accurate work while occupying the minimum of floor space. The price is a boon to cramped budgets. Promote the efficiency of your production with this quality machine! Get the facts! They're yours simply for the asking . . . write today.

Heat Treating and Controlled Atmospheres

by H. W. Gillett

Some drawbacks in heat treatment that were accepted as inevitable ten years ago may now be eliminated when it is economic to do so. Instead of making either an oxidized, or stained product, requiring pickling, or one with a decarburized bark, it is now possible to heat treat without injuring the surface. The principle of box-annealing with the introduction of a protective atmosphere has been greatly widened.

Instead of slow heating of a heavy box from the outside, electric resistors or radiant tubes supply the heat close to the work, and the gas atmosphere is chosen to suit the particular temperature and particular steel composition in question. At the low temperatures and with the low carbon steels common in the process annealing that is applied in the mill to a huge volume of sheets, an atmosphere of partly burnt fuel gas, without fussy purification, does a fairly good job.

Factors Which Are Fatal

But the annealing of high carbon steels, the normalizing of any steel, and particularly the heating of medium and high carbon steels for quenching, bring in conditions where moisture and CO_2 are fatal. In the early days this was not recognized by people who should have known better, and electric heat-treating furnaces were put on the market in which fuel gas and air were burned directly in the furnace chamber. The water vapor from the hydrogen in the fuel, thus directly introduced, did far more harm than occurs with no "protective gas."

These "gold brick" furnaces were soon stripped of their gadgets in the users' hands and operated without controlled atmospheres, but the need for clean hardening had to be met, so purification trains came into use by which water vapor was removed and only dry gas fed to the furnace. Then people slowly awakened to the fact that CO_2 is a bad actor, too, and further chemical purification was resorted to, to remove it. Finally, charcoal gas generators were put on the market which made gas higher in CO and lower in CO_2, so that the problem of CO_2 removal was minimized. The physico-chemical facts, that for a given temperature and given steel composition a certain $H_2 : H_2O$ ratio or $CO : CO_2$ ratio is required for the gas to be inert, and the further fact that H_2, or CH_4, and CO_2 will interact to produce H_2O, were finally yielded to as inevitable. Today, atmospheres of dry H_2 (from cracked NH_3); $CO + N_2$, and even almost pure N_2, are in wide commercial use, along with more complex, less pure, but cheaper, gas mixtures where the conditions are such that the impurities can be balanced, and the mixture thus made inert.

Bright annealing and clean hardening, without having to pickle off a heavy scale or to put up with a decarburized bark, are now realities.

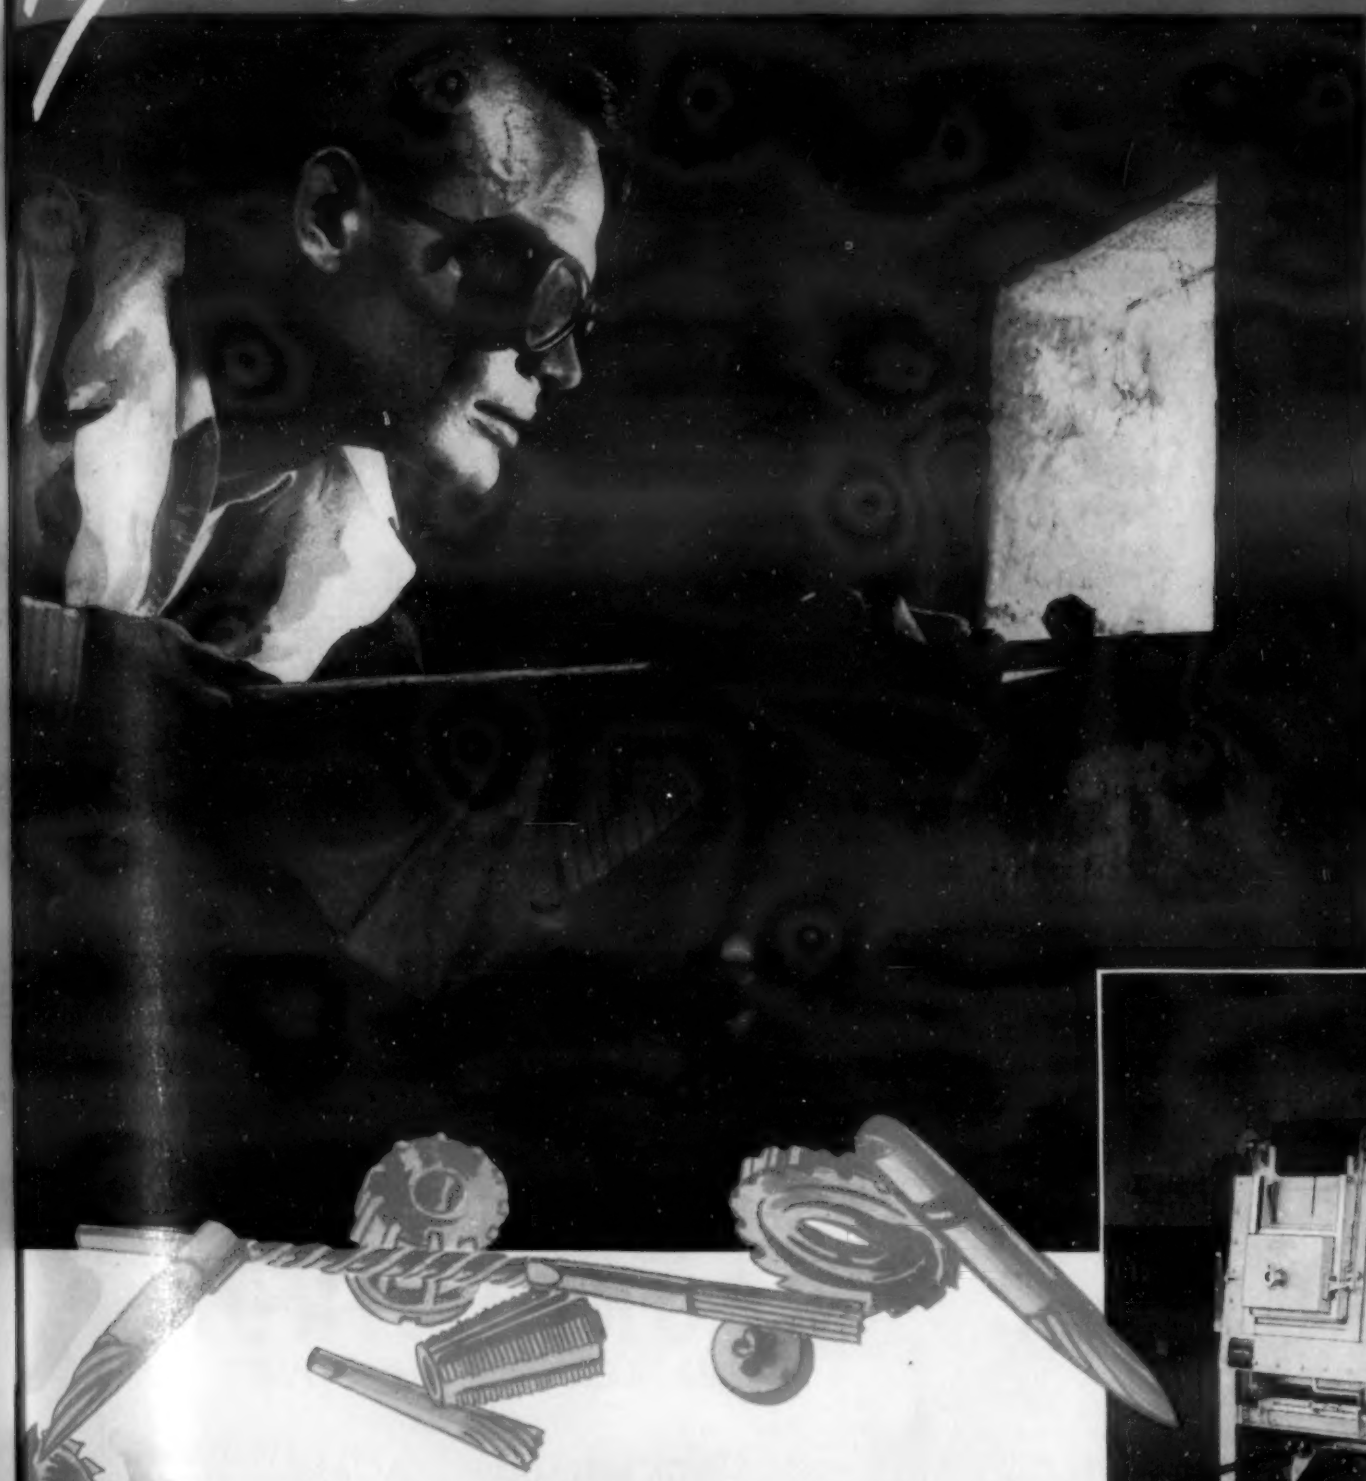
In analogous fashion, the use of copper brazing in a reducing atmosphere has grown into industrial prominence, but it is still a shocking commentary on industrial backwardness that this cheap method of assembly remains neglected by many who might use it to great advantage.

Unsolved Problems

Protection in the soaking pit, and during forging or rolling, much more difficult of accomplishment, remain as unsolved problems, and there is still much to be done in the actual application of the protection of high-speed steel during hardening. An electrical resistor that will not be attacked by the various atmospheres necessary to protect different steels is also to be desired.

At low temperatures, as in tempering after hardening, where scaling is no problem, temperature uniformity, even in a closely packed charge, is accomplished by forced circulation of hot air. Stagnant atmosphere tempering furnaces are now obsolete, and modern furnaces make tempering almost a fool-proof process.

Temperature Uniformity



The problem of temperature uniformity at higher temperatures, where heat transfer is by radiation, is not yet solved in any fool-proof fashion. However, the campaign of education being embarked upon by the group of furnace makers, with the backing of the War Department, will help emphasize the importance of proper loading of furnace charges.

On the whole, the past decade in heat treatment has been marked by the commercial application of fundamental facts of chemistry and physics.

Again ..AT THE METAL SHOW!.. CHAR-MO

SEE THIS REMARKABLE NEW ATMOSPHERE FURNACE IN ACTION! ...SEE IT TREAT "MOLY" STEEL WITHOU DECARBURIZATION!

[The Char-Mo furnace is licensed for use under Atmospheric Control Patents owned by The Sentry Company, Foxboro, Mass.]

The Char-Mo furnace is available in both the preheat and superheat type as shown above. The atmosphere gas is generated in a self-contained generator which forms an integral part of the superheat furnace. The preheat furnace is supplied with atmosphere gas from the generator in the superheat furnace . . . In addition to the horizontal muffle type furnace as shown, the Char-Mo furnace is also available in a vertical muffle or pit type.

● So great has been the interest in the Char-Mo furnace, first shown at last year's Metal Show, that it again will be shown in operation at this year's show in Chicago. If you have not seen this outstanding furnace in operation don't miss this opportunity of seeing it.

You will be able to see for yourself the ease, simplicity, and certainty with which molybdenum alloy and other steels—both high speed and carbon—are heat treated without decarburization and without the use of borax or other protective coatings. There is no fuss, no bother, no worry about those expensive tools of yours when treated in the Char-Mo furnace. Borax or other protective coatings are eliminated by the use of a self-generated atmosphere, the composition and flow of which can be easily and quickly varied to be in equilibrium with all types of steels. Char-Mo atmosphere is a mixture of balanced carbon oxides largely diluted with inert nitrogen and is produced in a generator which is an integral part of the superheat furnace.

Builders of ATMOSPHERE FURNACES and HARDENING, DRAWING, NORMALIZING, ANNEALING FURNACES for CONTINUOUS or BATCH OPERATIONS

Even if the nature of your work does not require a Char-Mo furnace you are still cordially invited to visit our booth in the gas section. There will be on hand a competent staff of engineers who will be glad to discuss with you any heat treating problem you may have.

SURFACE COMBUSTION CORPORATION • TOLEDO, OHIO

SURFACE SC COMBUSTION

Powder Metallurgy

by Fred P. Peters

Powder metallurgy is not the brand new art that the tremendous interest currently displayed in it might suggest. By 1929 the use of powder practice to prepare ductile tungsten, tantalum and other high-melting metals had become an old, familiar story; industry had already been introduced to the possibilities in the extra-hard cemented carbides for tool and die materials, made by pressing and sintering high-melting carbide and low-melting cobalt powders; the use of metal powders for paint pigments, for calorizing and similar metal-coating operations, for magnesium flares, for metal spraying, etc., was well established.

The last decade, however, has witnessed an ever-accelerating application of metal powder technique to the production of such industrial products as bearings, welding electrodes, electrical contacts, permanent magnets, magnetic cores, wear-resistant facings, dynamo brushes, dental inserts, medallions, etc. This review will concern itself largely with this fastest growing phase—the manufacture of industrial products by compacting metal powders—to which some writers would even confine the full meaning of the term "powder metallurgy" itself.

In Bearings

Great impetus was given to the application of powder metallurgy by the need for better bearings for the automotive industry. Copper-lead "alloys" and leaded bronze bearings were among the first to be made by powder practice. Almost simultaneously came the development of the now-familiar graphitic bronze and the porous "oil-less" bearing. These are made by pressing and heat treating (sintering) mixtures of copper, tin and graphite powders to produce a uniformly interlaced porous mass which is later impregnated with oil; in operation the oil seeps regularly from the body of the bearing by capillary action to the bearing surface, providing automatic lubrication.

Porous bearings are now being made from materials other than bronzes. Light metal bearings made by conventional metallurgy are growing in use in Germany, and it seems likely that powder practice may provide a means for improving and controlling the anti-friction and other properties of aluminum alloy bearings, provided methods of reducing the oxide content of aluminum powder mixtures can be developed. The use of bearings compacted from iron powders is already growing rapidly, although it still is hampered by the lack of a large supply of high quality, cheap iron powder.

Powdered Iron

In fact, there has been considerable recent activity in adapting "iron" of various sorts to powder practice. Carbonyl-iron powder is the basis of highly pure iron compacts that are widely used for magnetic cores in electrical, radio and television equipment. A British cast iron powder ("Pacteron") is being hot-pressed to make small bearings and non-porous gears that are said to have a tensile strength of 80,000 lbs. per sq. in. The new permanent magnet materials, *e.g.* of the Alnico type, are also often prepared by powder processes. One recently announced German development is the dispersion of ferromagnetic powders in molten low-melting non-magnetic materials; the powders are forced by an external field into positions they retain after solidification of the matrix, thus giving compacts of controllable directional magnetic or electrical properties. More than one laboratory is today working on the problem of making steel products by powder metallurgy.

With respect to raw material powders in general, refinements in manufacturing operations and particularly in the quality and purity of the powders have been steady though unspectacular. As previously mentioned, what this country still needs is a good 5-cent iron powder. The recent development of the hydride process, described in these pages, provides a supply of powdered hydrides that under suitable and simple conditions can be induced to release their hydrogen to leave a very pure, reactive metal powder available for alloying. Currently there is also much interest in the preparation of alloy powders, a field that will probably be intensely developed in the future.

IRON POWDER

We have sponsored, and are today supplying, the only low priced highly controlled iron powder used by the American Market.

Our staff of recognized specialists in Powder Metallurgy are prepared to advise our trade specifically with regard to iron powder, and also on powder metallurgical problems in general.

We invite your inquiries.

SPONGE IRON
FOR MELTING PURPOSES

FOR METALLURGICAL AND CHEMICAL USE

Steels made with Hoeganaes Sponge Iron as a raw material show a Vibration Dampening Capacity *Twice* that of similar steels made with scrap as a raw material. Reference: Report of Investigations, Bureau of Mines, R.I. 3229, page 63—Obtainable from us or directly from B.M. Our regular grade of Sponge Iron for melting purposes contains carbon about .35%. We are today prepared to entertain inquiries for low carbon Sponge Iron.

EKSTRAND & THOLAND, INC.

441 LEXINGTON AVE., NEW YORK CITY

DETROIT CHICAGO

A 1939 EXPOSITION FEATURE OF COMMANDING INTEREST:

THE PRESENT DAY APPLICATION OF Metal Powders

A DEMONSTRATION EXHIBIT OF THE WHERE AND THE WHY OF POWDER METALLURGICAL TECHNIQUE . . . .

[BOOTH D-108 NATIONAL METAL EXPOSITION]

Our exhibit at the forthcoming Metal Exposition in Chicago might be termed A Graphic Study of Powder Metallurgy's Application to the uses of modern industry. It has been prepared as a service to those who are interested in learning of latest actual, practical developments in this field. Through the demonstration of what is being done with metal powders — how and why the technique of powder metallurgy is being employed in various cases — we hope to give a clearer conception of the possibilities — and the limits — of this art.

We invite you to make full use of our booth as "Information Center" on Metal Powder applications. We have had nearly a quarter-century of experience in supplying metal powders for many and various purposes.

Our exhibit at Chicago will be evidence of an exceptional knowledge of this particular branch of metallurgy which is at your disposal.

MD POWDERS

METALS DISINTEGRATING COMPANY

ELIZABETH, NEW JERSEY

Manufacturers of Metal Powders since 1916

Technique in Powder Compacts

The general techniques employed for making powder compacts have developed along logical lines. The traditional low-temperature pressing followed by high temperature sintering is still most widely used, because it is easiest on dies and also because it is the most convenient method of producing porous products. Hot compressing—simultaneous pressing and sintering—is, however, receiving increasing attention for the production of non-porous compacts, for it offers definite sizing advantages and often much better ultimate physical properties than can be obtained by the sequential treatment.

A special kind of hot compressing, liquid-phase bonding—or, as W. D. Jones calls it, "fritting"—sems to be due for a vigorous revival in interest. This technique, long applied to the cemented carbide tool materials has been adapted by Smithells and his associates in England to the production of a sintered tungsten-copper-nickel alloy from powder mixtures containing 5 per cent Ni and 2 per cent Cu. A very dense non-porous structure consisting of tungsten bonded with a Ni-Cu-W alloy is achieved by hot pressing in a neutral atmosphere at 1400 deg. C. (at which the nickel and copper are liquid) and 5 tons per sq. in. for 1 hr. The sintered alloy, developed for radium containers, has already found other important applications.

Apparatus

The most important advances in compacting equipment have been in apparatus for heat treating and pressing. Special high frequency induction and electrical resistance heaters providing facilities for atmosphere or vacuum control have been developed. Recently hydraulic presses have been built that avoid previous slipping and air-trap difficulties through the incorporation of a double reservoir, which permits a very rapid stroke—about 20-30 cycles per min. Also, modern presses and dies are so designed that previously objectionable percentage density differentials are reduced to harmless levels. The speed at which future processing advances are made will depend in large part on the development of presses and dies capable of producing larger compacts to even finer dimensional tolerances than the present 0.001 in., and able also to withstand the much severer operating conditions encountered in hot compressing.

Some Other Major Developments

by Edwin F. Cone

The foregoing array of discussions include many of the chief fields in the metal and alloy industry but there are numerous others which it has not been possible to include. Several of the latter could have been very ably discussed by competent men. In the following paragraphs, however, an attempt is made to very briefly call attention to a few developments in certain fields, not included in the other reviews. At best these must be sketchily treated.

The Blast Furnace

We are indebted to Prof. T. L. Joseph of the University of Minnesota for the following résumé of important developments:

1. Improvements in gas washing which have provided cleaner gas. 2. Improvements in the concentration of Eastern magnetites and wider use of sinter produced from such concentrates. 3. Lower sulphur specifications for pig iron has stimulated the use of soda ash in the runner and ladles. 4. Wider use of automatic stock line recorders and greater attention to proper distribution of the charge. 5. Technique for operating on slack wind, banking and fanning furnaces. 6. Emphasis on quality or uniformity and less on tonnage records. 7. New pig machines, higher capacity and lower cost. 8. Small pigs or piglets. 9. Daily capacity of most of the recent furnaces about 1,000 tons.

The Bessemer Convertor

Space permits only mention of the announcement of the Jones & Laughlin Steel Corp. of control of the Bessemer convertor by photo-electric cells insuring flame regulation and better steel.

Titanium

Extensive have been the applications of titanium in the metallurgy of steel, iron, and non-ferrous alloys in the decade. According to a leading producer of titanium and its alloys, some of these are as follows:

In steel—the most important has been its use in stainless to prevent intercrystalline corrosion and embrittlement. A similar effect has been utilized more recently in plain chromium steels (about 5% Cr) for decreasing the hardening after rapid cooling as in welding. A recent development is its use in the low-alloy, high strength steels to improve welding and so on.

In gray iron—the influence of titanium is now better understood; finer graphite can be produced.

In non-ferrous alloys—one of the largest uses is in aluminum alloys where it has a useful grain-refining effect. It is introduced as a master alloy of Ti and Al or "titanium hardener." The manufacture by hydride reduction and other methods of a pure cupro-titanium alloy for use in high-conductivity copper is noted. Titanium in nickel alloy welds to improve ductility is cited.

Phosphorus

Ten years ago phosphorus in steel was considered in an entirely different light from the present. The new use that is outstanding is in the low-alloy, high strength steels—to raise the tensile and yield strengths and to enhance atmospheric corrosion. Steel, with 0.10 to 0.15 per cent P, has a relative life, based on a given loss from corrosion in atmosphere, of the order of two to three times that of a similar steel with normal phosphorus content. It is one of the few elements which increases the yield strength of steel at a greater rate than the tensile strength—advantageous in the low-alloy, high strength steels.

Some other interesting applications of phosphorus in steel (also from a communication from Dr. C. H. Lorig of Battelle Memorial Institute) include the following: Phosphorus improves the tensile properties of steel at moderately elevated temperatures. This fact led to the discovery that phosphorus could be utilized in enameling sheet to improve sag resistance. This has been demonstrated by one large steel company; it also improves the adherence in enameling.

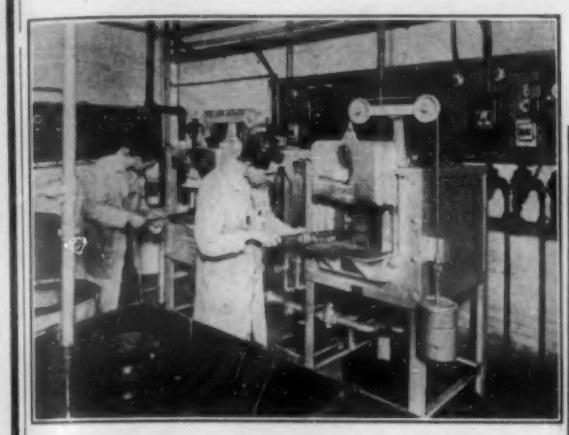
Other citations include: Phosphorus added to structural rail steel is claimed to be beneficial as to wear resistance, weldability, machinability and corrosion resistance. A Japanese investigator claims that phosphorus benefits the properties of magnetic alloys as to permeability and hysteresis loss.

In non-ferrous metals—its use as a deoxidizer has developed. Small amounts of phosphorus in zinc galvanizing baths, added as a P-Sn alloy, gives the zinc coating a better luster with superior adherence and ductility.

In phosphate coatings on steel distinct progress has been made.

Beryllium

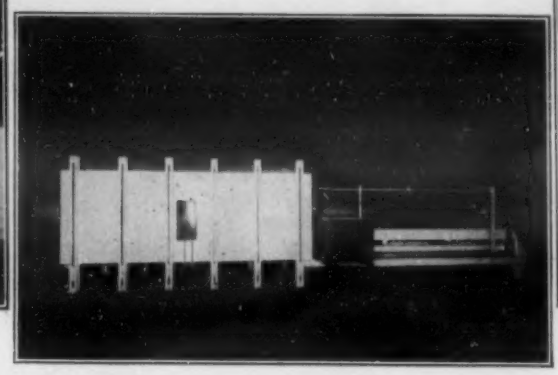
Ten years ago very little was heard of the metallurgical uses of beryllium. Today it is expanding as an alloy with copper, both as castings and as a wrought product. This has been its widest application. Not much has been developed in the alloys of nickel and beryllium though rumors are plentiful concerning German uses. An authority tells us that he thinks that the beryllium-aluminum alloys have the brightest future. That it is a precipitation hardening alloy is a distinct advantage.



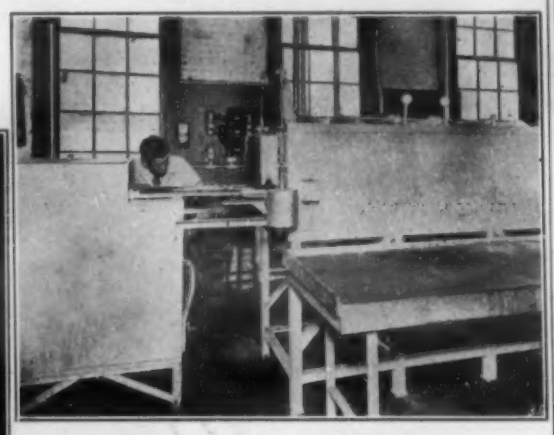
As a constituent in certain alloy steels, the future will no doubt witness considerable progress.

Lead

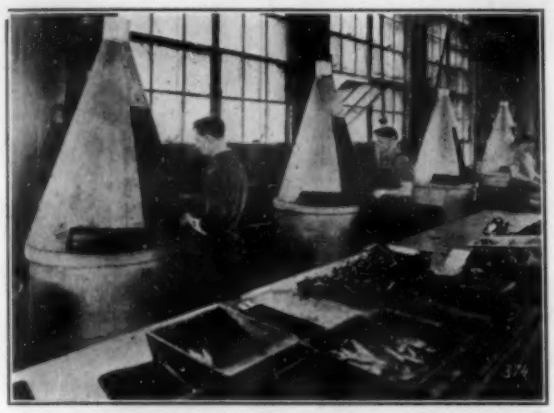
The outstanding metallurgical development in lead has been its introduction into open-hearth steel to produce a free-machining lead-bearing steel, "Ledloy." This has been quite fully discussed in several technical articles.



Large quantities of lead alloyed with less than 0.10 per cent Te are being used particularly as sheet and pipe in equipment in the

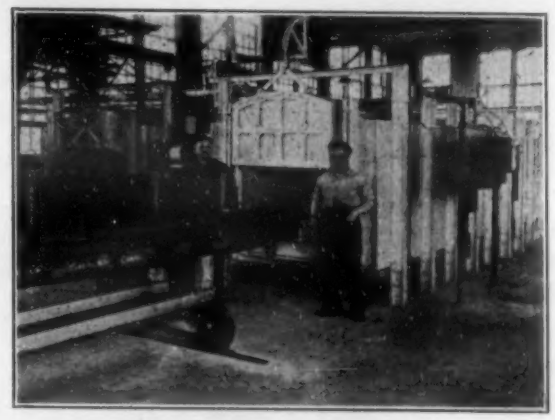


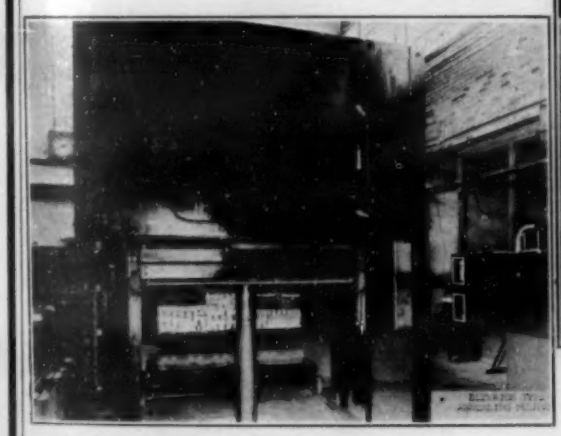
"AMERICAN"
Builds All Types Industrial Furnaces



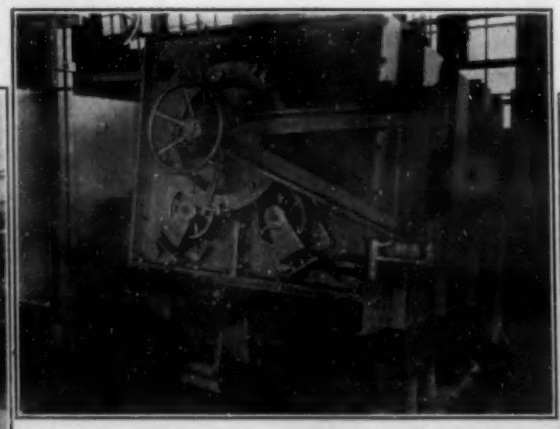
Preheating and High Speed Tool Hardening Furnaces with Atmospheric Control.

Continuous Rotary Retort Bright Annealing Furnace. 106 K.W. in two zones.

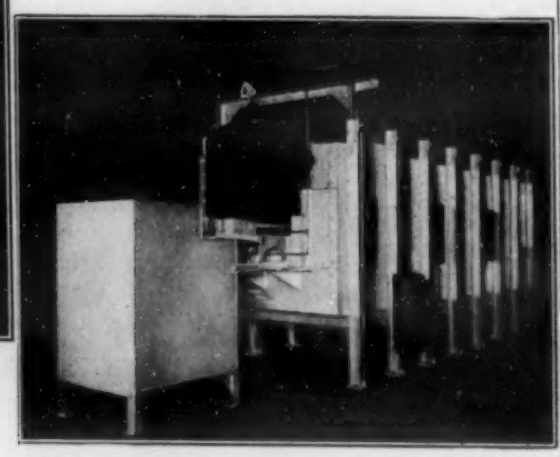




Automatic Pusher Type with Atmospheric Control, sealed quench, and automatic discharge.



Cyanide, Lead, and Salt Pot Furnaces.



Roller Rail Tube Annealing Furnaces. 237 K.W. in three zones.

Elevator Type Annealing Furnace with Artificial Atmosphere.

Rotary Rocking Retort Gas Carburizing Furnace.

Continuous Pusher Inclined Hearth Clean Hardening Furnace. 150 K.W. in three zones.

"AMERICAN" Electric Furnaces comprise a complete line covering a temperature range of from 350°F. to 2500°F. Nearly 100 standard units and as many more special types are available for application to your work.

Whatever your requirements, they can best be met with "AMERICAN" Electric Furnaces.

HEAT TREATING TRIUMPHS

●

PERLITON 45

A FASTER LIQUID CARBURIZER

Basically the same Perliton that has provided a true carbon case, speed and economy for five years . . . with these added advantages:

1. It is a unit product—combining carbon and eutectic salt in one mixture.
2. It contains a patented catalytic agent which speeds up carbon penetration without altering chemical reaction. **It's at least 20% faster on short heats.**
3. It has higher thermo-conductivity. Temperatures lowered by fresh charge will rise faster, saving on the time cycle.

CUT-MAX

STRAIGHT CUTTING OILS AND BASES

A new all-inclusive series, featuring CUT-MAX Base No. 7 which contains a minimum of 18% superactive added sulphur . . . and will cover 90% of all machining needs. Remember, in cutting oil preference it's **"Houghton, 2 to 1."**

HOUGHTO-CLEAN 145-S

FOR CLEANING OIL-QUENCHED WORK

Wets out faster and removes all traces of salt and oil rapidly and efficiently.

HOUGHTO-BLACK

LOW TEMPERATURE BLACKENING SALT

Parts to be blackened are submerged in a mixture of HOUGHTO-BLACK and water, maintained at a temperature of 290°-300°F.—below the tempering range. No expensive equipment required.

FERRITROL

AN ANTI-SCALING COMPOUND

Applied to steel to prevent oxidation and scaling at high temperatures. It consists of a vehicle and pigment shipped together in one package.

●

Our Booth, M-311, at the Show will also show those time-tested products that the Metal Industry knows so well and favorably:

No. 2 Soluble Quenching Oil—Drawing Compounds—Solid Carburizers — Houghto-Cleans — Metal Cleaners — Rust Preventives — Pickling Inhibitors — Grinding Oils.

●

E. F. HOUGHTON & CO.

Chicago - PHILADELPHIA - Detroit

chemical industry, according to information supplied by G. O. Hiers of the research laboratories of the National Lead Co., Brooklyn. Also, lead alloys with 1 per cent Ca or less are being used for bearing metal alloys such as "Satco" metal. The addition of lead to aluminum alloys (up to 1.5% Pb) is important in the field of free cutting or free machining metals (similar to Ledloy).

Low-Alloy, High Strength Castings

Somewhat comparable to the low-alloy, high strength structural steels is the development and production of a similar grade of steel castings—and for a similar purpose: Weight reduction with increased strength for use in bolsters, side frames, etc., in railroad equipment, and so on. Decided strides have been made with emphasis on the manganese-nickel and manganese-vanadium grades. Of late a maganese-titanium steel has appeared and reports concerning its success are reliable, with interesting possibilities.

Machine Tools

There have been striking changes in the materials incorporated in machine tools in quite recent years—greater use of alloy cast iron (Ni, Cr, V and Mo), of alloy steels and of non-ferrous alloys, substituted for the plain irons and steels. This has resulted in almost revolutionary developments in the efficiency and accuracy of these highly important machines. The scope of this development is authoritatively discussed by an article in our September and October issues.

Silver

Expanding industrial uses of silver has been a leading development in the decade. A pictorial article in this issue depicts one phase of this as carried out by a leading producer of silver alloys. Powder metallurgy has entered this field commercially. There have been experiments in the use of silver as an alloy in stainless steel and in non-ferrous alloys. The researches of Battelle Memorial Institute in the development of silver alloy bearings have produced valuable results.

Other Items

Much has been learned about precipitation hardening during the decade. This is particularly true in the non-ferrous metals. This is touched on by one or two of the reviews. In steel, both copper and some other alloys are precipitation, or age-hardening, alloys.

Continued progress has been made in centrifugal casting in both the ferrous and non-ferrous fields. Witness the use of ferrosilicon in the Delavaud process and the recently developed process of the Ford Motor Co. for producing differential and rear axle gear blanks. Another company is said to be casting unusual shapes centrifugally. The prospects in this field are encouraging.

In induction melting and heating decided advances have been made. Within the decade large Ajax high frequency furnaces up to 4-ton capacity have been installed. The use of induction heating in heat treating is an outstanding development which has reached the commercial stage not only in selective heat treating of crankshafts (Tocco process) but also of many other both cylindrical and irregular shapes. A new development is the hardening by induction of the internal surface of pipes, cylinders and the like.

In forgings, distinct progress has been made in the production of both hammer and drop forgings of alloy and stainless steels.

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Precipitation Hardening

Kempf (page MA 32 R 2) gives a good introduction to the principles of precipitation hardening, addressed to foundrymen, but useful to metallurgical engineers in general.—H.W.G.

High Yield Strength Steels

Hoff (page MA 54 L 1) gives an interesting picture of the status of such steels in Germany even though the attitude toward other countries' developments is a smug one.—H.W.G.

Kick Out the Cementite

According to Naumann (page MA 58 L 7) the secret of avoiding attack by hydrogen upon steel at high temperature and pressure, is to alloy it so that Fe_3C is replaced by more stable alloy carbides.—H.W.G.

Flame-Cutting of Cast Iron

Cast iron is much more resistant to oxidation, and hence to flame-cutting, than steel. Nevertheless, flame-cutting of cast iron is accomplished quite readily by a special combination of flame adjustment and cutting technique. The preheating flames are adjusted to be carburizing; tips and oxygen pressure are the same as for cutting mild steel.

The best technique is as follows: Play the preheating flames along the line of cut, from top to bottom, until the cast iron is well heated at the place where the cut is to start. Then turn on the cutting oxygen. As soon as the cut has started, manipulate the torch to give the tip a semicircular oscillating motion extending equally each side of the kerf centerline, and advancing slowly to make the cut. Watch carefully that the advance is kept in step with the cutting action. A relatively smooth-appearing cut will result.

Flame-cutting of cast iron is limited at present to demolishing castings and to making alterations and repairs to machinery. Where heavy parts are to be removed, particularly in close quarters, the cutting torch saves time and money. Alterations to machines often require only a part of a casting to be cut away. Repairs of cracks or breaks in large cast iron members by welding require preparation of the section by veeing. Here the cutting torch is of great value. The most extensive present application of flame-cutting of cast iron is probably for this operation (page MA 34 L 9).—E.V.D.

Al Cable Sheath

Herrmann (page MA 60 R 8) reports that high purity Al is replacing Pb for cable sheath to some extent in Germany. Sufficient plasticity is claimed to be achieved by an anneal at 350 deg. C., which gives an elongation of 40-55 per cent.—H.W.G.

High Test Iron

Piwowarsky (page MA 16 L 7) questions whether going to tensile strengths above 50,000 lbs. per sq. in. by reduction in C content of cast iron does not so reduce the chances of getting good castings as to do more harm than good to the foundry industry.—H.W.G.

The Auto-squeezing Mold

Erichsen (page MA 19 L 7) describes a mold for casting billets, made of high expansion Ni steel, which, as it heats up from the molten metal poured into it, progressively decreases the volume of the mold cavity, so that feeding is claimed to be unnecessary.—H.W.G.

Ferrosilicon

In order to avoid the possibility of evolution of PH_3 during storage or shipment of ferrosilicon, the P content is held low. Liebscher (page MA 15 L 10) comments that P-free iron scrap, or wrought iron, are used as raw material to supply the Fe. It seems odd to class wrought iron, which is usually very high in P, together with P-free iron scrap, whatever that is. "Free" must be a relative term.—H.W.G.

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Molds for Centrifugal Castings

According to a German article (page MA 84 L 7) special bronzes high in Al have been developed as a material for centrifugal molds. They contain 3 to 11 per cent Al and 15 to 5 Ni + Fe. For iron molds additions of 1 to 10 per cent Al are suggested. Such molds, when first used, are covered with a thin skin of Al_2O_3 which retards heat transition from molten metal to mold, thus preventing excessive stresses in the mold and guaranteeing more uniform cooling conditions and increasing mold durability.—E.F.C.

Metals in Aircraft

Metallurgical engineers in the aircraft industry achieve maximum strength/weight ratio by using either high-strength metals or light-weight metals, or judicious combinations of both. An article in *Steel* (page MA 114 R 2) discusses carbon, alloy and stainless steels used in aircraft, while Le Coeuvre (page MA 116 R 1) exhaustively treats of light metals in the same field. Whether you favor stronger heavy metals or lighter weak metals, or are undecided, you'll find much of interest in both articles.—F.P.P.

Steels for Chisels

A summary of the chisel steels used in England is offered by Sanderson (page MA 94 R 1) together with the heat treatment applied. They vary all the way from plain carbon to those containing W, Cr or V, one or all of these—E.F.C.

"Were t'other dear charmer away"

Smithells (page MA 110 L 3) remarks that one doesn't have hydrogen unsoundness or oxygen unsoundness in metal frozen from a melt; unsoundness occurs only when both are present together.—H.W.G.

Grain Size Determinations

To the methods for determining austenitic grain size, Baruzdin (page MA 112 L 10) adds hydrogen etching of the grain boundaries under reduced pressure at the desired elevated temperature.—H.W.G.

Electroplating on Aluminum

Electroplating of harder or more corrosion-resistant metals on Al aids the designer in building parts that combine the light weight of Al with the often more desirable surface properties of heavy metals. Two articles this month (pages MA 104 L 6 and MA 105 L 10) are concerned with electroplates on Al, with operating details and applicability of available processes given.—F.P.P.

Physiology

Brisbois and Cartwright (page 84 L 6) mention "straight-sided, round-shouldered, short-necked heads," Herrmann (page MA 102 R 8) the "backside" and at first we thought Le Coeuvre's "chignolle" (page MA 116 L 2) had something to do with a hair-do. Exhaustive investigation in technical dictionaries reveals that a chignolle is a small bevel gear hand drill.—H.W.G.

Controlling the Open Hearth

Application of automatic control equipment to open-hearth furnaces is discussed by Bradley (page MA 86 L 1). Among the benefits cited is a better quality of steel at about half the average of 6,400,000 B.t.u.'s used to produce a ton of ingots in 1928-1929. Comparison of before-and-after costs of operation shows average savings of 9 per cent in tonnage, 12 per cent in refractories and 8 per cent in fuel.—E.F.C.

Fish Scale in Enameling

Two articles on this not entirely piscatorial problem are abstracted this month. Kerstan (page MA 106 R 1) gives a remarkably thorough, practical report on the causes of fish scale formation; and Hoff and Klärding (page MA 106 R 6) concentrate on a single factor believed to be the culprit. Paeans of praise from the abstractor emphasize the value of both contributions.—F.P.P.

Cutting the Cloth

Textiles and sewing may seem a long way from metallurgical engineering, but Kent (page MA 105 R 5) points out that proper choice of cloth, method of assembly and details of sewing make lots of difference in buffing wheels.—H.W.G.

DIE CAST—MACHINING OPERATIONS CUT 77%

Capitalize upon

LESS & EASIER MACHINING

with ZINC ALLOY DIE CASTINGS

BEFORE the manufacturer of this intricate part turned to a ZINC Alloy Die Cast construction, he had to perform 40 major machining operations on each unit. Now he performs only 9—and these are easy and light.

Says the designer of the part: "The adoption of a one-piece die cast body has reduced machining costs and tool replacements, eliminated operations, and simplified design so as to actually reduce the number of parts."

These are facts worth pondering—especially when you consider the importance of the part in the finished product. It's the main body of an automobile speed governor. When assembled it contains shafts, bearings, springs, filters, pistons, levers, and adjustment screws—parts whose operation depends upon accuracy and complexity in the encasing body. Machine labor in a case like this can mean the difference between profit and loss.

With ZINC Alloy Die Castings, machining is always minimized. Most of it is eliminated by the accuracy and intricacy to which parts can be cast—and any machining which cannot be avoided is simple. Cuts are light, and the metal is free-cutting and easy on tools.

How much machining do *you* do in making *your* metal parts? Perhaps ZINC Alloy Die Castings can save you production dollars as well as improve your products. Consult a commercial die caster—or write to the New Jersey Zinc Company, 160 Front Street, New York City.

The Research was done, the Alloys were developed, and most Die Castings are specified wi

HORSE HEAD SPECIAL (99.99+%) ZIN

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Low-Temperature Brazing Alloys

Research work in recent years has developed new brazing alloys (MA 155 L 9) with lower melting points. Some of these are silver alloys, which incorporate the brazing characteristics of silver solder in compositions containing less silver—in certain cases as little as 10%. Other new brazing alloys are composed of copper and phosphorus.

One new silver brazing alloy contains 15% silver, 80% copper and 5% phosphorus. It is widely used for joining non-ferrous metals, principally copper, brass and bronze. It has a melting point of 1185 deg. F. and is free-flowing at 1300 deg. F. Another new silver brazing alloy has a medium silver content of approximately 50%, and the balance of about equal portions of copper, zinc and cadmium; it has an extremely low melting point (1160 deg. F.) and almost universal applicability.

Low-temperature brazing fluxes, that begin to fuse at about 800 deg. F., and at 1100 deg. F. are thin, active fluids which ensure thorough wetting of joint surfaces by these brazing alloys, are used. The combined use of the low-temperature brazing fluxes and the low-temperature brazing alloys makes possible an excellent joining medium, operating at low working temperatures. These new developments have broadened the field of application, and low-temperature brazing alloys are now used extensively for a great variety of work.—E.V.D.

High-Cr, Low-W High-Speed Steels in Russia

Steels with C 1.10, Cr 9.20, W 2.38, V 0.81 and C 0.98, Cr 8.68, W 4.08, V 1.56 are reported to stand up better than W 18, Cr 4, V 1 in cutting tests in "Low-Tungsten Substitutes for High Speed Steel" (page MA 148 L 3). This abstract also reports the amount of retained austenite after quenching and after single and triple draws at different temperatures. Do our high speed steels retain 65% austenite on quenching in oil and 29% after a single draw at 550° C. (1022° F.)?—O.E.H.

Two Points of View

Den Hartog and Rodgers (page MA 155 L 8) consider that cracking of welds is due to structural modification and not avoided by a stress-relieving anneal. Weisberg (page MA 156 R 8) finds that C-Mo piping must be preheated before welding and not allowed to cool before stress-relieving, if cracks are to be avoided.—H.W.G.

Blowholes in Castings

Bollenrath and Schiedt (page MA 145 R 6) remark that even in aircraft castings of light alloys, small blowholes are admissible if they are not in locations of maximum stress concentration.—H.W.G.

Die Dunking

Brass die castings are made with smooth surfaces (page MA 145 R 8) by dunking the die in a water suspension of some coating material between casts. But won't this slow up production, besides being mighty tough on the dies?—H.W.G.

Methuselah

According to Rowe (page MA 144 R 6) natural siliceous sands are "and always will be" the most common material for molds for non-ferrous castings. No such statement can be disproved, but how can one be certain that no radical change can take place in anything relating to metallurgical engineering?—H.W.G.

Powder Metallurgy

Honisch (page MA 183 L 2) cites several ways of making metal powder for pressing and sintering, but omits electrodeposition at a current density selected to produce a non-adherent deposit.—H.W.G.

Welding Molybdenum Steels

C-Mo steels are commonly preheated before welding and stress relieved afterwards. Welds made in this manner have practically the same tensile strength, elongation and impact value as the parent metal. Existing data, while incomplete, indicate good creep resistance of such welds also. Properly made welds in Mn-Mo, Ni-Mo and Ni-Cr-Mo steels also possess good physical properties.

From the standpoint of recovery in welding, Mo is one of the easiest elements to control. In the case of covered electrodes, up to 1% Mo has been introduced into the weld-metal from the coating. The percentage recovered decreases as the Mo content of the coating increases. Mo slightly increases the recovery of C in the weld-steel also (MA 160 R 9).—E.V.D.

AMAZINGLY DEPENDABLE...

HEAT RESISTING CASTINGS OF **MEEHANITE**

For *ten months* these MEEHANITE saddle castings in Chicago Bridge & Iron Company's Stress Relieving Furnace at Birmingham, Ala. have been withstanding *six hour heats at 1200° F.* with no signs of distress—evidence of real dependability.

Foreword

by L. F. REINARTZ

L. F. Reinartz
Chairman, Open-Hearth Committee

THE National Open-Hearth Committee of the American Institute of Mining and Metallurgical Engineers will hold its annual conference in the Cleveland Hotel, Cleveland, on April 26, 27 and 28. At the same time and place the Blast Furnace and Raw Materials Committee of the Institute will hold a meeting. From all indications, a record number of managers, open-hearth superintendents, metallurgists, chemists, and other operating men will be present at this conference to help discuss many problems of practical interest to steel men.

Five technical sessions will be held during the open-hearth conference, and three sessions will be held by the blast furnace and raw materials group.

During the first open-hearth session on the morning of April 26, a question, which is of vital interest to all operators at this time, will be discussed: "Employer-Employee Relations in the Steel Plant." Subjects such as safety, foremen training, metallurgical observers, checking open-hearth practice, and handling of grievances will be discussed. R. K. Clifford, general superintendent, Kokomo Works of the Continental Steel Corp., will preside. C. R. FonDersmith, open-hearth superintendent of Middletown Works, American Rolling Mill Co., will be vice-chairman.

At their first session during the morning of April 26, the blast furnace group will discuss the effect of solution loss reactions on blast furnace economy, and effects of low slag volume on cost and quality. H. A. Strain, assistant general superintendent of Carnegie-Illinois Steel Corp., Chicago, will be chairman and W. E. Brewster, blast furnace superintendent, Wisconsin Steel Works, will be vice-chairman.

At noon both committees will attend a welcoming luncheon. Harold Burton, mayor of Cleveland, and D. B. Gillies, president of the A.I.M.E. will address the group.

E. C. Smith, chief metallurgist, Republic Steel Corp., Cleveland, is chairman of the Cleveland local reception committee. Other members of this committee are: Walter M. Charman, W. F. Conlin, Huntington Downer, Howard P. Eells, Jr., Carl P. Guthrie, J. D. Knox, Paul J. McKimm, and C. A. Thayer.

The open-hearth committee will discuss the use of refractories during the afternoon session on Wednesday, April 26. Invitations have been sent to members of the refractory division of the American Ceramic Society to take part in these discussions. Gilbert Soler, research manager, Timken Roller Bearing Co., will act as chairman, and Harley C. Lee, Columbus, Ohio, will assist him as vice-chairman. Some of the subjects for discussion are: (a) New ideas for the installation of furnace bottoms with particular reference to plastic chrome bottoms. (b) Improvements in checker construction. (c) Refractories for tap holes, runners, ladle accessories and hot tops. (d) How can the open-hearth operator be assured of uniform and satisfactory refractory material?

At the afternoon session the blast furnace committee will hear about blast furnace practice in South Africa, and will discuss freight cost of iron ore, and a low temperature, vacuum process for iron ore reduction. Horace Allen, Evergreen Mines Co., Cleveland, will act as chairman, and J. H. Slater as vice-chairman.

The Thursday morning conference will be devoted to a joint discussion by both committees of problems which are of vital interest and importance to both groups. Such subjects as:

What the open-hearth requires from a blast furnace.
How open-hearth requirements can be met.
Economical amount of open-hearth slag used in a blast furnace.
Use of mixer type ladles.
Substitution of blown metal.
Effect of hot metal analysis and casting temperature on the quality of open-hearth steel.

Clyde E. Williams
Secretary, Open-Hearth Committee

R. H. Sweetser
Chairman, Blast Furnace Committee

are some of the interesting topics that have been provided for discussion. L. F. Reinartz, manager, Middletown Works of the American Rolling Mill Co., will be general chairman of this session. J. W. Kinnear, chief metallurgist, Homestead Works of Carnegie-Illinois Steel Corp., and A. J. Boynton, vice president, H. A. Brassert & Co., Chicago, will be co-chairman. A lot of valuable and enlightening information should be developed at this session. At noon the executive committee of the open-hearth will hold a luncheon meeting. The members of the blast furnace and raw materials group will also have a luncheon meeting.

During the afternoon of April 27 the members and guests of the joint committees will visit the large modern plant of the Republic Steel Corp. in Cleveland.

At 6:30 p.m. there will be a cocktail party in the Cleveland Hotel followed by the annual good fellowship dinner at 7:30 p.m. Harry Sain, special representative of the Industrial Commission of the State of Ohio, will deliver a short, inspirational and humorous talk on the subject: "Safety in the Steel Plant."

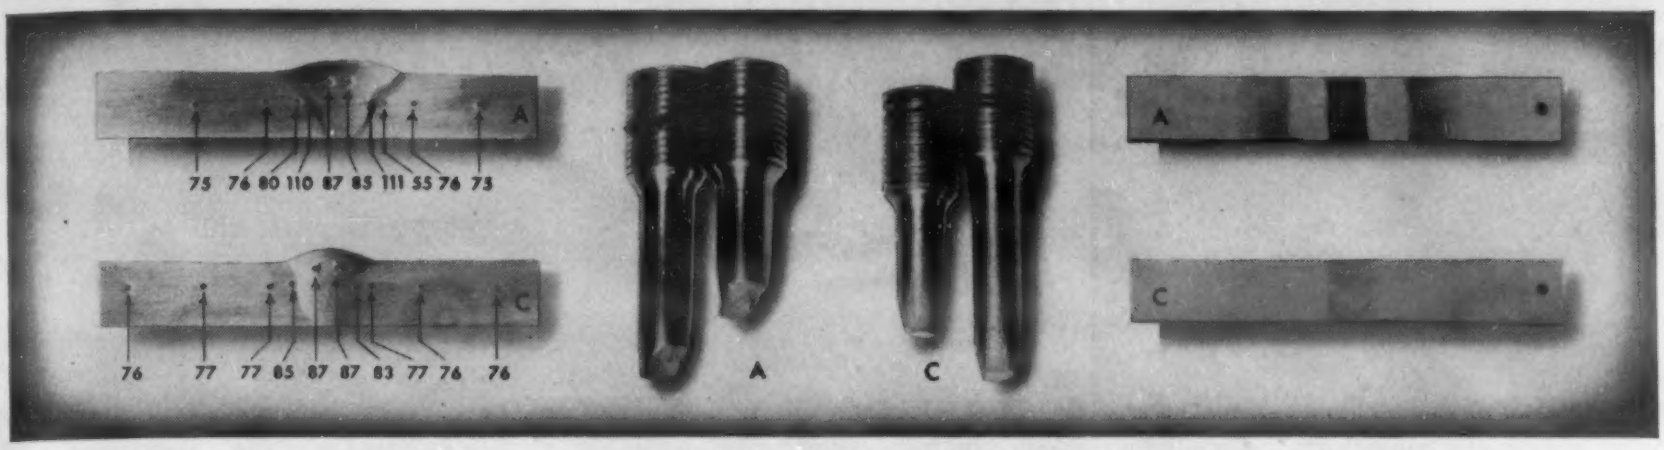
Friday morning the open-hearth group will discuss operations in the open-hearth department. At this session the following subjects will be discussed: (1) Description of a pilot open-hearth furnace. (2) Construction and operation of a new furnace at the Pittsburgh Steel Co. (3) Instrumentation on a modern open-hearth furnace. (4) Pyrometers for metal bath temperatures. (5) Bottom pouring practice. (6) Crowe slag pockets. (7) Description of a novel design for an open-hearth furnace without a front wall. (8) Use of light weight scrap. A. P. Miller, assistant general superintendent of Inland Steel Co., will be chairman of this session, with W. C. Kitto, open-hearth superintendent, Pittsburgh Steel Co., vice-chairman.

During the afternoon of April 28, the open-hearth group will discuss quality problems connected with the manufacture of open-hearth steel. As usual, this conference should create a great amount of interest. Questions relating to effect of aluminum on grain size in killed steels, use of other deoxidizers on grain size, effect of patching furnace bottoms on grain size control, use of silico-manganese in forging and other steels, as well as the effect of mold design on the quality of killed steels will be discussed.

A great many subjects coming under the classification of rimming steel will be discussed. Some of these are:

(a) Best FeO content of slag for rimming 0.20 per cent carbon steels.
(b) Percentage of automobile scrap used in making extra deep drawing steels.
(c) Effect of high and low residual manganese on rimming steels.
(d) Best place for aluminum additions—in ladle or in molds.
(e) What defects in finished steel can be traced back to open-hearth practice.

Slag control will come in for its share of discussion. Many of the methods now in current use will be discussed.



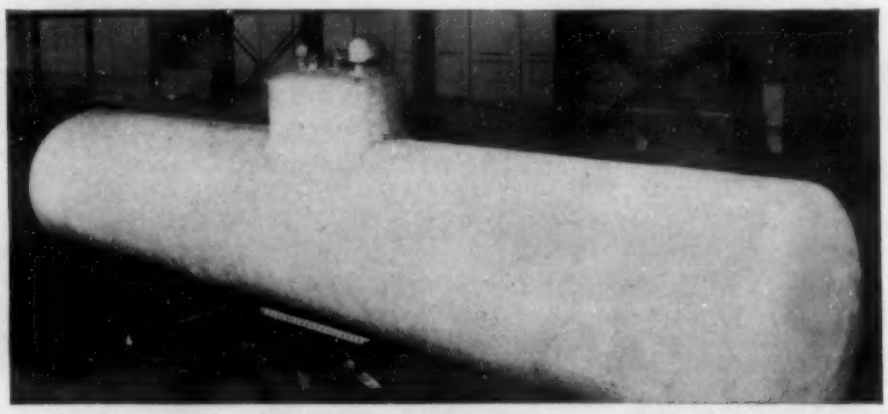
At this conference a synopsis of a paper read at the St. Louis Iron & Steel Scrap convention showing types of scrap available for open-hearth use will be read.

All open-hearth operators will receive a copy of the complete program early in April, and each individual is asked to familiarize himself with the questions, and be prepared to enter the discussion. The experience of those who have attended these meetings the longest, and secured the most benefit, is that only if each member or guest gives the group the benefit of his personal experience can there be a frank exchange of ideas for the benefit of all those attending the conference.

F. H. Crockard
Secretary, Blast Furnace Committee

How COLUMBIUM Simplifies Welded Fabrication of High-Chromium Steels

Rockwell B hardness is indicated on these 4 to 6 per cent chromium steels welded with 24 per cent chromium-12 per cent nickel rod, tested as welded. Steel A contains no columbium; steel C contains 0.51 per cent columbium. Note that the columbium-bearing steel is practically free from air-hardening in the zone adjacent to the weld.



These tensile specimens are 12 to 14 per cent chromium steels air-cooled from 1650 deg. F. Steel A contains no columbium; steel C contains 0.80 per cent columbium. Notice how soft and ductile the columbium-bearing steel appears. The test results indicate that steel C actually is about twice as ductile and less than one-third as hard as steel A.

These 18 per cent chromium-8 per cent nickel steel specimens were oxy-acetylene welded and then exposed to hot nitric-hydrofluoric acid. Steel A, without columbium, shows severe corrosion in the zones adjacent to the weld. Steel C, with 0.44 per cent columbium in the plate and 0.99 per cent columbium in the welding rod, shows no corrosion.

IN steels containing from 3 to 16 per cent chromium, columbium minimizes air-hardening. In stainless steels of the 18 per cent chromium—8 per cent nickel type, columbium prevents intergranular corrosion even after long exposure to temperatures ranging from 750 to 1650 deg. F. Hence, when all these chromium steels contain a small amount of columbium and are welded with columbium-bearing welding rod, subsequent annealing is unnecessary. This eliminates a costly and time-consuming fabricating step . . . You should specify columbium in your high-chromium steels to lower fabricating costs.

For over thirty years, we have produced "Electromet" ferro-alloys and metals for use in making steel. Ferrochromium for adding chromium to steel and ferrocolumbium for adding columbium to steel are two of these ferro-alloys. If you make steel, our metallurgists will gladly help you use "Electromet" ferro-alloys to meet the analysis your specifications call for. If you use steel, information and metallurgical assistance are available to make your use of alloy steels more profitable.

The word "Electromet" is a registered trade-mark of Electro Metallurgical Company.

Because this 8000-gallon chemical tank was made of columbium-bearing stainless steel welded with columbium-bearing welding rod, it did not have to be annealed after welding to assure full corrosion resistance.

Quenching of this 16-foot-long autoclave from a resolution temperature of 2000 deg. F. was eliminated by constructing it of columbium-bearing stainless steel welded with columbium-bearing welding rod.

Tentative Technical Program

Wednesday, April 26

9:00 A.M.—Registration—Open-Hearth and Blast Furnace and Raw Materials Committee—Mezzanine Floor

Open-Hearth Committee

10:00 A.M.—Opening Address—L. F. Reinartz, general chairman, National Open-Hearth Committee, A.I.M.E., Ball Room (Mezzanine Floor)

Session on Industrial Relations

R. K. Clifford, Chairman; C. R. FonDersmith, Vice Chairman

"The Settling of Grievances" by Russell Chaffin, director of industrial relations, Continental Steel Corp., Kokomo

"Safety in the Open-Hearth" by C. R. FonDersmith, superintendent open-hearth, The American Rolling Mill Co., Middletown

Subjects for Discussion

(a) Training and practical use of metallurgical observers in the open-hearth

(b) Training foremen and men in the open-hearth department to follow cost, quality, fuel and repairs

(c) What is done to improve working conditions in the open-hearth department

(d) Checking open-hearth practice for quality

Blast Furnace and Raw Materials Committee

10:00 A.M.—Opening Address—Ralph H. Sweetser, chairman, Blast Furnace and Raw Materials Committee, A.I.M.E.—Empire Room (Parlor Floor)

Session on Solution Loss and Slag Volumes

H. A. Strain, Chairman; W. E. Brewster, Vice Chairman

"Effects of Solution Loss Reactions upon Blast Furnace Economy" by P. V. Martin, asst. supt. blast furnaces, South Works, Carnegie-Illinois Steel Corp., Chicago.

"Low Slag Volumes and Resulting Effects on Cost and Quality" by G. E. Steudel, division supt. of blast furnaces, South Works, Carnegie-Illinois Steel Corp., Chicago

12:15 P.M.—Welcoming Luncheon—Open-Hearth and Blast Furnace and Raw Materials Committee—Red Room (Mezzanine Floor)

Addresses of Welcome

Harold Burton, mayor of Cleveland;
D. B. Gillies, president, A.I.M.E.

Open Hearth Committee

2:00 P.M.—Session on Open Hearth Refractories

Gilbert Soler, Chairman; Harley C. Lee, Vice Chairman

1. Discussion of Furnace Bottoms:
   a) Plastic chrome bottoms
   b) Use of various types of magnesite, such as Seawater, Thomasite, Austrian, Canadian, Washington, etc.
   c) How to keep bottoms clean. How are old bottoms resurfaced? What materials are used?
2. Use of Basic Brick and Other Special Materials in Open-Hearth Furnaces other than Bottoms:
   a) Bulkheads
   b) Back walls
   c) Roof
3. Improvements in Checker Construction:
   a) Special brick and special settings
   b) Multiple checkers
   c) Other designs
   d) Do checkers run hotter in insulated furnaces?
4. Refractories and Tapholes:
   a) Materials used
   b) Control practice
5. Runners and Ladles:
   a) What progress is being made with basic materials?
   b) Other materials and designs
   c) Methods used for lining ladles; composite ladle lining (2 different types of brick—same ladle)
6. Ladle Accessories: Sleeves, Stopper Heads and Nozzles:
   a) Materials and designs in use for sleeve brick
   b) Materials and designs in use for stopper heads
   c) Materials and designs in use for nozzles
   d) Type of bond between the sleeve brick and mixtures used for nozzle well.
   e) What special qualities are desired for a nozzle?
7. Hot Tops and Mold Plugs:
   a) Various types of hot tops in use
   b) Relative advantages of permanent hot tops vs clay hot tops, in different types of steel in regard to cost and quality
   c) Mold plugs
8. What Refractory Specifications Are Necessary for the Open-Hearth Operator in Order to Obtain Uniform and Satisfactory Refractory Materials?
   a) Bottom materials
   b) Basic and chrome brick, etc.
   c) Ladle brick and fire brick
   d) Silica brick
   e) Pit refractories: Sleeve brick, stoppers, nozzles, hot tops, mold plugs
   f) Other refractory materials

(Continued on Page A11)

(Continued from Page A10)

9. Needs for Future Development by the Refractories Industry in Order to Increase the Operative Efficiency, Improve Quality and Lower Overall Cost in the Open-Hearth.

Blast Furnace and Raw Materials Committee

2:00 P.M.—Session on Operating Practice; Raw Materials
Horace Allen, Chairman; J. H. Slater, Vice Chairman

"Blast Furnace Practice in South Africa" by J. A. L. Ortlepp, African Metals Corp., Johannesburg

"Low Temperature—Vacuum Metallurgical Process" by Alfred Musso, Cons. Engr., New York City

"Freight Costs of Iron Ore" by H. M. Roche, Cons. Engr., Dover, N. J.

Thursday, April 27

9:30 A.M.—Joint Session—Open-Hearth and Blast Furnace and Raw Materials Committees

L. F. Reinartz, General Chairman
J. W. Kinnear, Jr., Co-Chairman for Open-Hearth
A. J. Boynton, Co-Chairman for Blast Furnace

Subjects for Discussion

What the open-hearth requires from the blast furnaces Meeting the open-hearth requirements.

What is the economical amount of open-hearth slag that can be used in the blast furnace with respect to final ingot costs?

Have mixer type ladles justified their adoption—(1) where they have replaced small ladles; (2) for new installations?

To what extent may blown metal be substituted for steel scrap. What grade of iron is most economical for the production of blown metal?

Can the use of high silicon iron in the open-hearth be justified by the extra amount of iron ore it will reduce?

"Effect of Hot Metal Analysis and Casting Temperature on Open-Hearth Quality" by L. H. Nelson, asst. open-hearth supt., Republic Steel Corp., Buffalo, N. Y.

12:15 P.M.—Executive Committee, Open-Hearth Committee—Luncheon Meeting

12:15 P.M.—Blast Furnace and Raw Materials Committee—Luncheon Meeting

Inspection Trip

2:15 P.M.—Plant Visit—Open-Hearth and Blast Furnace and Raw Materials Committees—Republic Steel Corp., Cleveland Plant. Chartered buses will leave the Hotel Cleveland at 2:15 p.m. for the plant. Members and delegates will be guided through the 98-in. continuous strip mill, the largest continuous mill in the world. Buses will leave the plant at 5:00 p.m. for the return trip to the hotel.

6:30 P.M.—Cocktail Party—Red Room

7:00 P.M.—Fellowship Dinner-Smoker—Ball Room. Tickets $2.50 including Cocktail Party

Speaker: Harry Sain, special representative, Industrial Commission of Ohio—"Safety in the Steel Plant"

(Continued on Page A12)

INGOT YIELD INCREASED UP TO 3% with LAPIX

LAPIX definitely reduces porosity and secondary pipe. Introduced a year ago and widely discussed at last year's Open Hearth Meeting, this insulating material substantially reduces top discards. Smokeless, odorless, finely powdered, LAPIX has a positive record of increasing ingot yield as much as 3%. Only 1½ lbs. are needed per ton of ingot, therefore adequate protection is afforded at an average cost of 6 cents per ton. For further information call the Houghton Man.

PYRO THE SIMPLIFIED OPTICAL PYROMETER

YOU CANNOT AFFORD NOT TO OWN ONE!

The Only Self-Contained, Direct Reading, Rugged and Fool-Proof Instrument for Steel Plants, Foundries, Laboratories, Etc.

Unique construction enables operator to rapidly determine temperature even on minute spots, fast moving objects or the smallest streams; no correction charts to consult, no accessories, no upkeep. New concentrated test mark and ease of operation permit unusually close and rapid temperature determinations. PYRO is standard equipment with the leading plants in your industry.

Stock Ranges 1400° to 5500° F.

Pyro Radiation Pyrometer

The ideal instrument for Furnace or Kiln use. Gives actual heat of material aside from

furnace or kiln temperature. Does not require a skilled operator—strictly automatic. Eliminates personal errors. Always ready to tell within three seconds any shortcomings in your equipment.

Write for special bulletins.

The Pyrometer Instrument Co.
107-9 Lafayette St. New York City

(Continued from Page A11)

Friday, April 28

Open Hearth Committee

9:30 A.M.—Session on Open-Hearth Operations—Ball Room
A. P. Miller, Chairman; W. C. Kitto, Vice Chairman

"Construction and Operation of an Experimental Open-Hearth Furnace" by Harold K. Work, manager of research and development, Jones and Laughlin Steel Corp.

Subjects for Discussion

Discussion of the construction and operation of the new furnace at the Pittsburgh Steel Co.

Instrumentation of the modern open-hearth furnace:
- a) Draft control
- b) Automatic fuel air ratio control
- c) Automatic reversal
- d) Roof temperature control

Special pyrometers for bath temperature recordings

Bottom pouring practice:
- a) Improvement of the ingot surface compared to top pouring and is it justified
- b) Tundish or basket pouring practice
  1. Improvements in surface and interior quality of ingots

Crowe slag pockets:
- a) Application
- b) Advantages

Use of Light Scrap

Open-Hearth Committee

2:00 P.M.—Session on Open Hearth Metallurgy
C. H. Herty, Jr., Chairman; E. G. Hill, Vice Chairman

I. *KILLED STEEL*

Does aluminum act on grain size as effectively when in a combined state, such as ferro-aluminum, as in regular stick or shot aluminum?

What other final deoxidizers other than aluminum are in use and what effect have they on grain size?

Does bottom patching material have any effect on grain size control?

On forging quality steels of large grain size, is it better to over-deoxidize in the furnace or be on the lean side in furnace deoxidation and finish deoxidation in the ladle?

The use of silico-manganese in forging and other steels

How does mold design affect the quality of the ingot?

II. *RIMMED STEEL*

In making 0.07 to 0.09% C rimming steel, will the reduction in carbon from the range 0.15 0.20% be best accomplished by oreing down the heat or bringing down the carbon with rods? Which method is preferable in regard to the oxidizing action in the steel itself?

What is the best FeO content of slag for rimming 0.20% carbon steel?

What percentage of automobile scrap can be used in making extra deep drawing steel sheets?

Do copper additions or residual copper make rimming low carbon steel sluggish?

What effect does high or low residual manganese have on rimming steel?

In making low carbon rimming steel, where is the best place for aluminum additions—ladle —molds?

Does a 2 to 3-in. rise in a rimming ingot, due to the addition of aluminum in the mold, have the same effect on skin thickness as a rising heat from furnace conditions?

How does mold design affect the quality of the ingot?

What defects in finished sheets can be traced back to open-hearth practice?

III. *SLAG CONTROL*

To what extent has FeO control in slags been applied to everyday production of steel?

Method of slag control:
- a) Run to a predetermined iron oxide.
- b) Slag cakes as guide
- c) MnO determination
- d) Method of raising or lowering FeO
- e) Control of viscosity
- f) Lime—SiO_2 ratio

Does the use of FeO control result in being able to hold to close analysis limits. How close?

How much iron oxide can be removed from the steel through the decrease in tne FeO content of the slag?

Cause and cure of foamy slags?

IV. *EFFECT OF CHARGE*

Analysis of scrap available for open-hearth use. Synopsis of paper read at St. Louis Iron and Steel Scrap Convention

Metallurgical advantages of deep vs. shallow baths. Ideal bath depth for forging steels. Why? Is more or less limestone used in a shallow hearth?

It is frequently said: "Low limestone charge is the cause for poor quality steel." Has anyone any positive evidence of this?

Which is more oxidizing—a cold pig metal or hot metal charge? Why?

Does cast iron in the charge affect the quality of steel? If limited, what per cent of total charge is permissible?

Relative advantage and disadvantages of high ore, low silicon iron in the basic open-hearth furnace

How can you be sure of a good run-off slag?

V. *GENERAL QUESTIONS*

What advantages are attributed to holding heats at the pouring platform?
- a) Length of time
- b) Kind of heat
- c) Live or killed
- d) If live steel, does a slag "boil" if a heat is held?

Working heats:
- a) Maximum ore and pig iron additions, and time of additions
- b) Effect of spar
- c) Use of sta-flux or burnt lime
- d) Use of mill cinder or roll scale
- e) Carbon at melt

In acid practice, what are the advantages in using lime in the slag and what is the best percentage?

Influence of the following factor on the speed of carbon reaction in the open-hearth furnace:
- a) Fuel
- b) Slag volume
- c) Atmosphere
- d) Temperature
- e) Influence of bath agitation
- f) Viscosity of slag

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Supersonics

Krainer (page MA 202 R 5) gives an interesting account of the use of high frequency sound waves to "grind" ore particles. What is needed now is a means of generating the waves on a scale sufficient to handle more than a thimbleful at a time.—H.W.G.

Laps

Preparers of metallographic specimens are pretty definite these days about wanting a minimum of flowed metal and a maximum of retained inclusions. Several ways of meeting these demands are described on page MA 110. Ellinger and Acken (R 3) use 50-50 Pb-Sn disks, whereas Jarrett (L 8) prefers laps of cast iron and of lead. Modern apparatus and technique makes all the more amazing the results obtained by the early microscopists.—J.S.M.

Ersatz

Claus tells us (page MA 230 L 3) that German red brass will be standardized as 85-5-7-3 and alleges that Pb-base bearing metals have totally replaced those of Sn-base.—H.W.G.

Another Tool Alloy

Haensel (page MA 232 R 2) claims that an annealed cast iron containing 3.9 per cent C and 5 per cent Mn is suitable for a cutting tool.—H.W.G.

Cephalodic Quadrupeds

We've heard of "fish scale" but "octopus-like graphite" is a new one. "Pigs containing octopi" would make an excellent thesis (page MA 204 R 7).—C.H.H.

Flakes in Steel

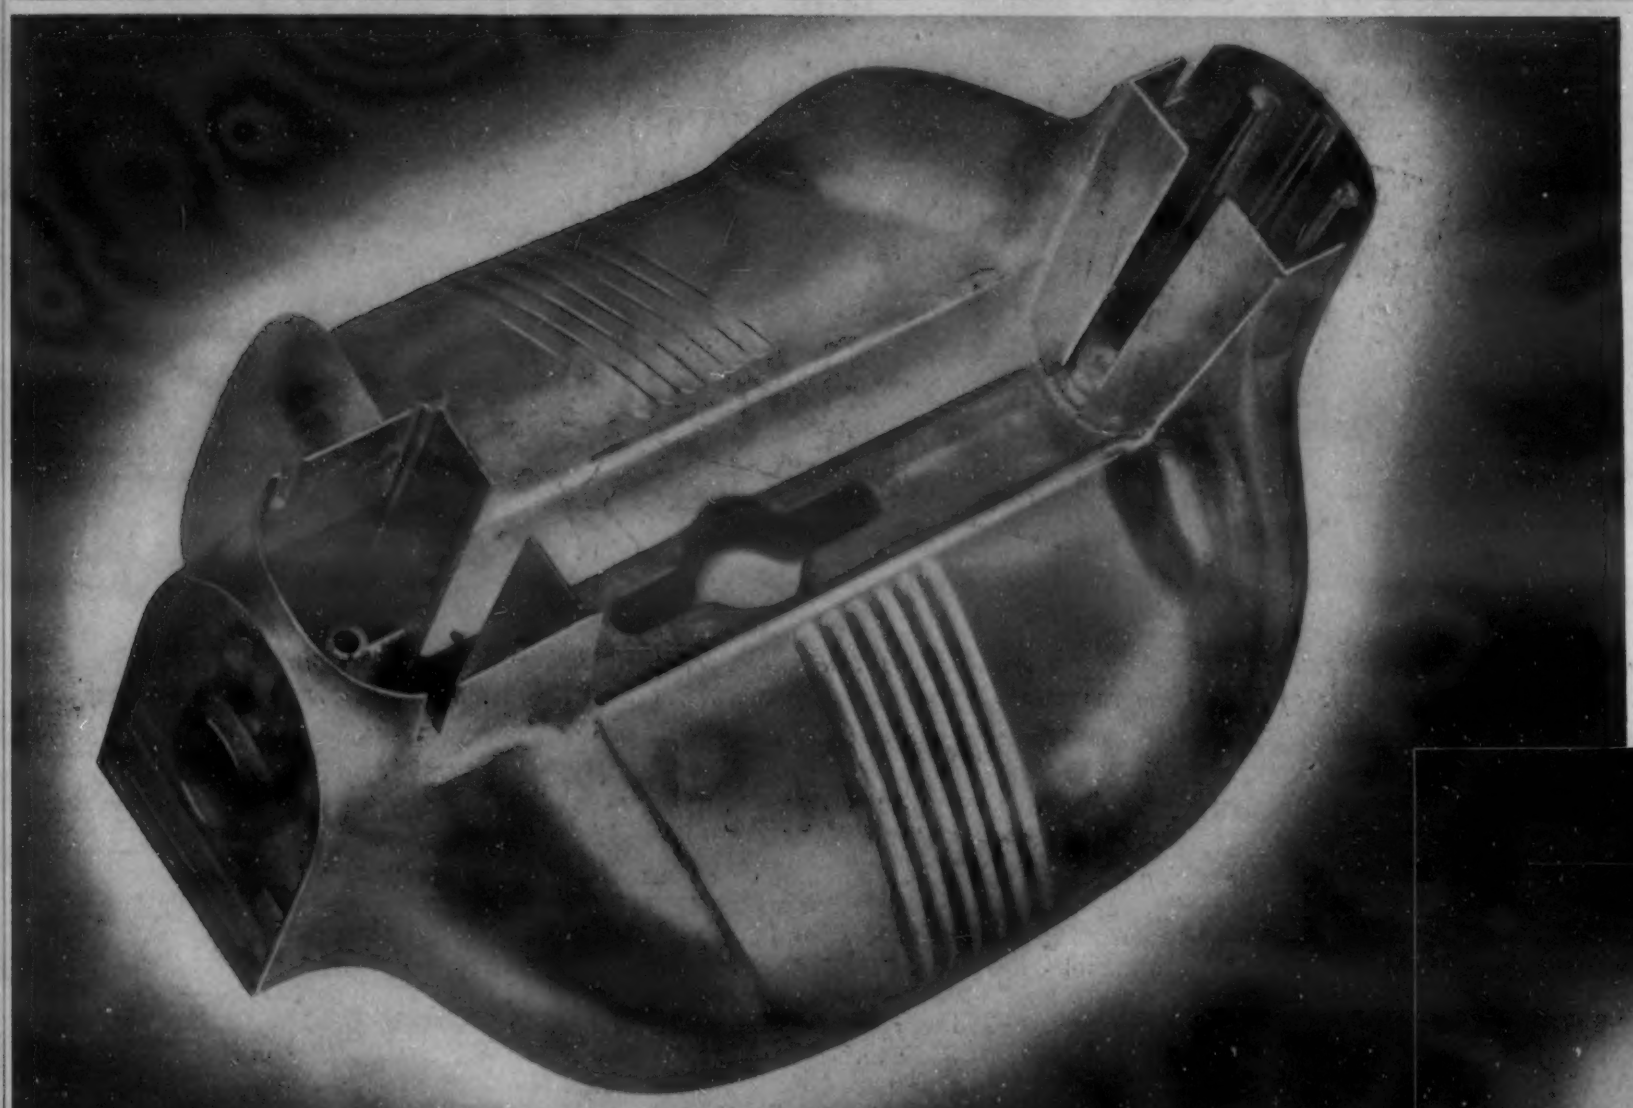
Japanese investigators (page MA 208 L 4) find that H_2 is not the only cause of flakes. They are developed by thermal and transformation stresses as well as by the chemical composition.—E.F.C.

Low Alloy Steels

The forming operations of the low-alloy high strength steels are not materially affected and are practically as good as those of ordinary mild steel, says Howard Stark (page MA 218 R 3). As to welding, electrodes of comparable analyses can be secured and many of these materials have better welding qualities than either flange or fire box steel. Stark makes the prophecy that it can only be a matter of time until industry will use these low alloy steels to a very great extent.—E.F.C.

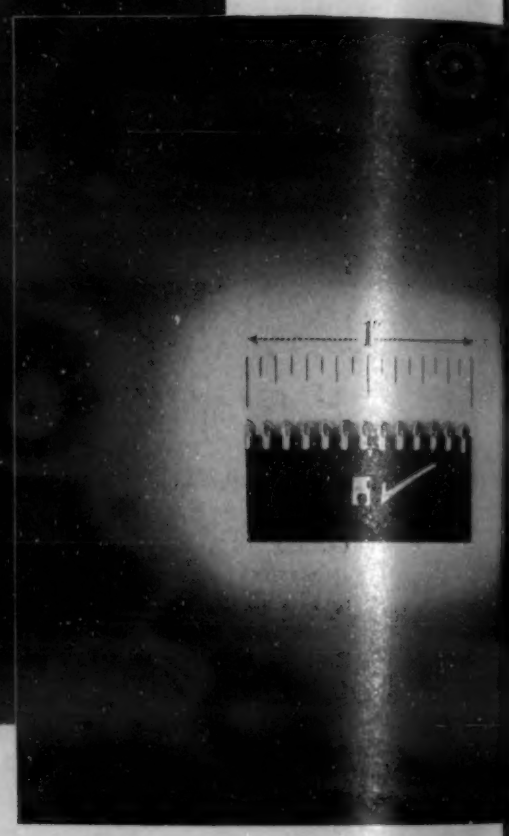
Heat Treating Light Metals

Reports are frequently published regarding Germany's expanding use of Al and Mg and their alloys. A description (page MA 216 L 6) of electric furnaces developed in Germany for the heat treatment of these products is valuable and interesting. The furnaces are large so as to accommodate the increasing size and use of the light metal structures. An interesting point is that the warping of light metal sheets by water quenching is overcome by using a spray or cold air blast.—E.F.C.



Steel from Oriental Sponge Iron

Kusaka (page MA 236 L 2), reporting on the properties of mild steel made from Chinese and Manchukuoan sponge iron, finds impact strength from 1.7 to 7 times better than that of "ordinary mild steel," depending on the heat treatment. This is the best rationalization we've had yet of Japan's course in China.—F.P.P.



Tellurium

The effects of tellurium additions are discussed in two articles this month. Hanson and Pell-Walpole (page MA 237 L 6) report improvement in work-hardenability and creep strength of tin by the addition of 0.1 per cent tellurium, while Hiers and Steers (page MA 237 L 9) ascribe improved fatigue and corrosion resistance, and useful work-hardenability to tellurium-containing lead.—F.P.P.

ZINC ALLOY DIE CASTINGS

11½ POUNDS
—or .022 gram

ZINC Alloy Die Castings are not restricted by size (within reason, of course). If a maximum or minimum were set it would probably be exceeded tomorrow.

1. SIZE—The large casting is a washing machine wringer frame—the small one (indicated with a check) is a slide fastener element. One weighs 11½ pounds and measures 18½" x 13" x 6⅝". The other weighs .022 gram and measures 7/64" x 1/16" x 3/64". Both are pressure die cast of ZINC Alloy.

2. INTRICACY—Whether a part be large or small, intricacy may be an important requirement. Note the *completeness* of the wringer frame casting—all of the necessary elements are embodied *in one part*. For example, provisions have been made in the end sections for fastening the wringer gearing. This means machining and assembling economies. A magnifying glass reveals the comparative intricacy of the slide fastener element, too.

3. ACCURACY—The die casting process makes it possible to secure extreme accuracy of shape and dimensions—of prime importance in the performance of the parts shown here. The ZINC Die Casting Alloys not only insure the retention of these dimensions, but they are responsible for the many other excellent physical characteristics as well.

If you would like to have more information on die castings we suggest that you consult a commercial die caster. We will be glad to answer your questions on the ZINC Die Casting Alloys.

THE NEW JERSEY ZINC COMPANY
160 Front Street New York

The Research was done, the Alloys were developed, and most Die Castings are specified w

HORSE HEAD SPECIAL (99.99+% UNIFORM QUALITY) ZIN

Annual Convention of the American Foundrymen's Association

HOTEL GIBSON, CINCINNATI, OHIO • MAY 15 TO 18

Introduction

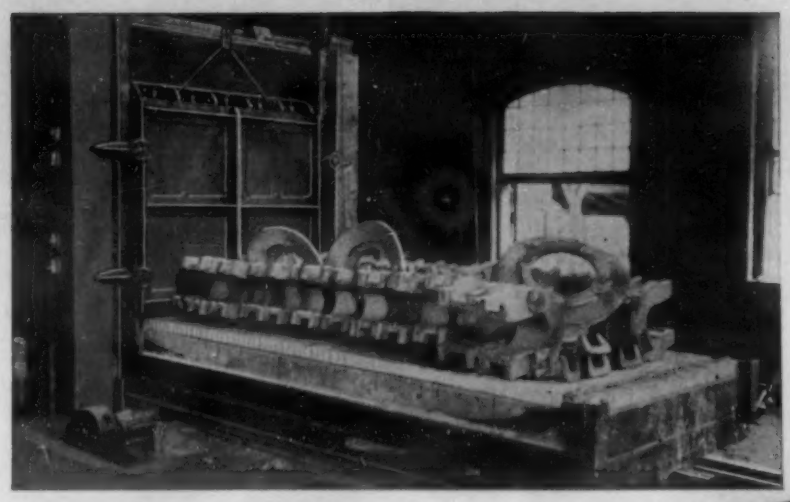
The American Foundrymen's Association will hold its forty-third annual convention at the Hotel Gibson, Cincinnati, Ohio, May 15 to 18. There will be no exposition. The president, Marshall Post, Birdsboro Steel Foundry & Machine Co., Birdsboro, Pa., will preside at the opening session, Monday morning, May 15. The Cincinnati District Chapter will act as host and has organized local committees for various activities.

Plant Visitation

In addition to the many industrial plants which will be open for inspection by small parties during the week, two special general group works visits will be organized. On Monday afternoon, May 15, the foundry and manufacturing departments of the Cincinnati Milling Machine Co. will be visited, while on Thursday afternoon, May 18, the convention will close with a visit to the Hamilton Coke and Iron Division of the American Rolling Mill Co. which will be followed by a buffet supper at the Hamilton Country Club.

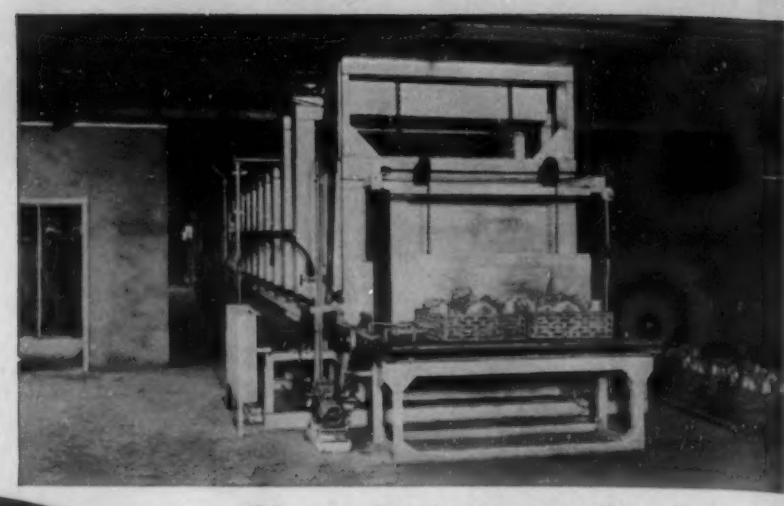
Awards at Annual Dinner

The annual dinner of the Association is to be held the evening of May 17. A feature will be the presentation of three major awards of the Association. To Harold S. Falk, vice president, Falk Corp., Milwaukee, the John A. Penton Gold Medal is to be presented in recognition of his leadership in promoting foundry apprentice training. Donald J. Campbell is to be presented with the W. H. McFadden Gold Medal as president of the Campbell Wyant & Cannon Foundry Co., Muskegon, Mich., in recognition of the achievements of this company in developing casting manufacturing processes. James R. Allan, assistant manager of the industrial engineering and construction department, International Harvester Co., Chicago, is to receive the J. H. Whiting Gold Medal in recognition of his engineering contributions to the Association and the foundry industry.



Non-Ferrous Division Dinner

The Non-Ferrous Division under the chairmanship of Harold J. Roast, Canadian Bronze Co., Montreal, has organized a social get-together dinner for Tuesday evening, May 16. As a special attraction for the members and their ladies at this dinner an address on "The Romance of Aviation" is to be given by William B. Stout, president, Stout Engineering Laboratories, Dearborn, Mich.



Lecture Course

An innovation this year is a three-session instructional lecture course on "The Microscope in Elementary Cast Iron Metallurgy." This course is to be given

(Continued on Page A7)

Large Steel Castings Large Steel Railroad Castings of various shapes and sizes are uniformly annealed in this single chamber car bottom type furnace.

Short Cycle Malleable Short cycle malleable castings are scale-free annealed—continuously—in this special atmosphere roller hearth type furnace.

Aluminum Castings— The accurate temperature control and uniform heat distribution necessary for aluminum is proved by these circular pits.

Furnaces for Every Industrial Heating Process

We Solicit Your Inquiries

Cast Brake Drums— Discharge end of a continuous oil fired roller hearth type furnace annealing automobile brake drums—continuously.

Steel Castings A car type installation consisting of two heating chambers, a cooling chamber, car puller and cross transfer car, for annealing 750 tons castings per month.

Annealing Valve Bodies Large valve bodies, pipe fittings and miscellaneous other castings are uniformly annealed in these two fuel fired car type furnaces.

Scale Free Annealing 40,000 lbs. of malleable castings per day are annealed absolutely scale free in these special atmosphere furnaces—The annealing time was reduced from 165 to 35 hours.

Recuperative Type Furnace Return recuperative type furnace annealing miscellaneous gray iron castings—continuously—the heat from the outgoing castings preheats the incoming material—saves fuel.

(Continued from Page A5)

by Roy M. Allen, noted metallurgical consultant, Bloomfield, N. J. Mr. Allen has revised and amplified into book form material which he presented before the 1931 A.F.A. convention. Mr. Allen's original material proved of such outstanding value that he was sought as the author of the first lecture course of the Association.

Steel Melting Symposium

For the first time in many years the Steel Division is giving special attention to a comparison of melting practices in different types of furnaces—acid and basic open-hearth, acid and basic electric, converter and induction. Each process is treated by an authority in his field and the whole will be given at the Symposium on the last day of the convention.

Technical Program

The technical program covers a wide range of papers and committee reports which will be presented in some 30 sessions. A detailed schedule of the program is given on other pages:

TENTATIVE TECHNICAL PROGRAM

Monday, May 15

MORNING

Opening Session

Address of welcome.

President's address, by Marshall Post, vice president and works manager, Birdsboro Steel Foundry & Machine Co., Birdsboro, Pa.

Malleable Cast Iron

"Atmospheres for Malleable Iron Annealing—Their Properties and Applications," by John Dow, Holcraft & Co., Detroit.

"White Iron for Malleableizing," by J. O. Klein, Texas Foundries, Inc., Lufkin, Tex.

"Shearing of Malleable Iron Gates," by S. D. Martin, Saginaw Malleable Iron division, General Motors Corp., Saginaw, Mich.

Nonferrous

"Production of Bronze Pressure Castings," by D. Frank O'Connor, Walworth Co., Boston.

"Crucible Melting," by G. K. Eggleston, Detroit Lubricator Co., Detroit.

Gray Iron Shop Course

Session 1—*"Cupola Practice."* Discussion leader: Donald J. Reese, International Nickel Co., Inc., New York.

AFTERNOON

Plant Visitation

Cincinnati Milling Machine Co.

EVENING

Malleable

Dinner and roundtable conference. Discussion on current practices.

Materials Handling

"Mold Equipment," by W. R. Jennings, John Deere Tractor Co., Waterloo, Iowa.

"Some Tests on Effectiveness of Water Under High Pressure for Cleaning Castings," by R. Webster, Hydroblast Co., Chicago.

Nonferrous

"Effects of Aluminum and Antimony on Physical Properties of Red Cast Brass (85-5-5-5)," by H. B. Gardner and C. M. Saeger, Jr., national bureau of standards, Washington.

"High-Conductivity Copper Castings," by A. B. Kinzel, Union Carbide & Carbon Research Laboratories, New York.

Annual business meeting of nonferrous division.

Lecture Course

Session 1—*"The Microscope in Elementary Cast Iron Metallurgy,"* by R. M. Allen, metallurgical consultant, Bloomfield, N. J.

Tuesday, May 16

MORNING

Gray Iron Shop Course

Session 2—*"Production of Uniform Dense Structures in High Test and Alloy Iron Castings,"* by M. A. Scott, Greenlee Foundry Co., Chicago.

Malleable

"Effects of Manganese on Second Stage Graphitization," by D. P. Forbes, Gunite Foundries, Rockford, Ill.

"Hydrogen in Solid White Cast Iron," by H. A. Schwartz and G. M. Guiler, National Malleable & Steel Castings Co., Cleveland.

Gray Cast Iron

"A Scientific Approach to a Foundry Problem," by L. A. Danse, Cadillac Motor Car Co., Detroit.

"60,000-Pound Cupola Iron," by E. L. Roth, Motor Casting Co., Milwaukee.

"Castings for the British Gas Industry," by F. Whitehouse, Newton, Chambers & Co., Ltd., Chapeltown, England. (Exchange paper of Institute of British Foundrymen.)

Nonferrous

"The Foundry and Metallurgical Science," by M. G. Corson, New York.

"Influence of Pouring Ladles on Quality of Red Brass," by R. W. Parsons, Ohio Brass Co., Mansfield, O.

Apprentice Training

"Apprentice Training," by Herman K. Ewig, Cincinnati Milling Machine Co., Cincinnati.

"Foundry Apprenticeship," by M. J. Gregory, Caterpillar Tractor Co., Peoria, Ill.

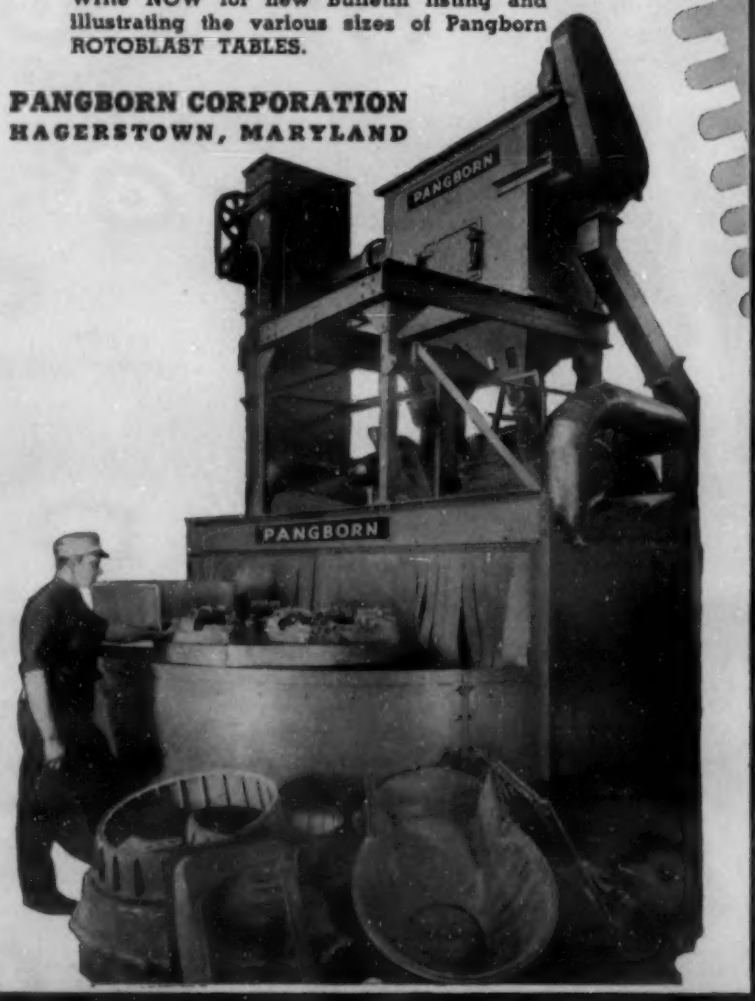
"10 MINUTES AGO
A NEW LOT OF DIRTY CASTINGS CAME DOWN HERE FOR ROTOBLASTING



"THANKS to the Pangborn ROTOBLAST TABLE pictured below, they'll be cleaned . . . bright as new silver dollars . . . in jig time . . . and off to the next finishing operation before anyone realized they were here!"

Service like this is everyday performance with Pangborn machines. Like other Pangborn Air and Airless Blast Cleaning equipment, this ROTOBLAST Cleaning Table is built to meet the toughest foundry cleaning problem without alibi . . . to finish its cleaning jobs in the quickest time—with the lowest power, maintenance and operating costs . . . and to produce castings so well cleaned and so beautifully finished that a good extra profit can be credited for the "Pangborn's" efficient performance.

Standard ROTOBLAST TABLES are now available in two types—each in three sizes. They are recommended for Thorough, Economical Blast Cleaning of flat and fragile Forgings; Steel, Iron, Malleable and Non-ferrous Metal Castings; Heat-treated parts, etc.

Write NOW for new Bulletin listing and illustrating the various sizes of Pangborn ROTOBLAST TABLES.

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Save the Surface

Graham (page MA 302 R 2) mentions a roll-swaging method for making a little tube from a big one that allows large reduction and avoids damaging the surfaces.—H.W.G.

Dry Ice Pack

To prevent buckling from thermal expansion during welding, Bailey (page MA 284 R 7) packs the parts to be welded, save for the seam itself, in dry ice.—H.W.G.

He Who Hesitates Is Lost

Friedman (page MA 271 R 7) comments that in hot pressing of non-ferrous metals, once flow is started it can be readily kept up, but any let-down in motion is fatal.—H.W.G.

Welding Carbon-Molybdenum Steel Piping

Welded C-Mo steel piping has been used successfully in the modern high-pressure, high-temperature, steam-electric generating plants for carrying steam at 900-1400 lbs. per sq. in. and 900-1100 deg. F. Most C-Mo steel piping installed to date has been arc welded, using a specially designed joint, with the electric preheating coils placed around pipe ends; the preheat temperature is maintained during arc welding by thermocouple controls. Small beads are deposited, using 1/8 in. and 5/32 in. diam. electrodes, and it is common practice to chip out about half of each bead laid to assure absence of unwanted inclusions in the weld. After completion of weld, it is stress-relieved by slow heating with the electric coils to a temperature of 1100-1200 deg. F., followed by slow cooling.

Because of the long time and many beads required to arc weld these joints, several piping fabricators have felt that possibly oxyacetylene welding might offer a means of expediting the operation and lowering costs. Accordingly, suitable C-Mo gas welding rods have been developed. Results of field tests made to date are most promising (page MA 280 R 7).—E.V.D.

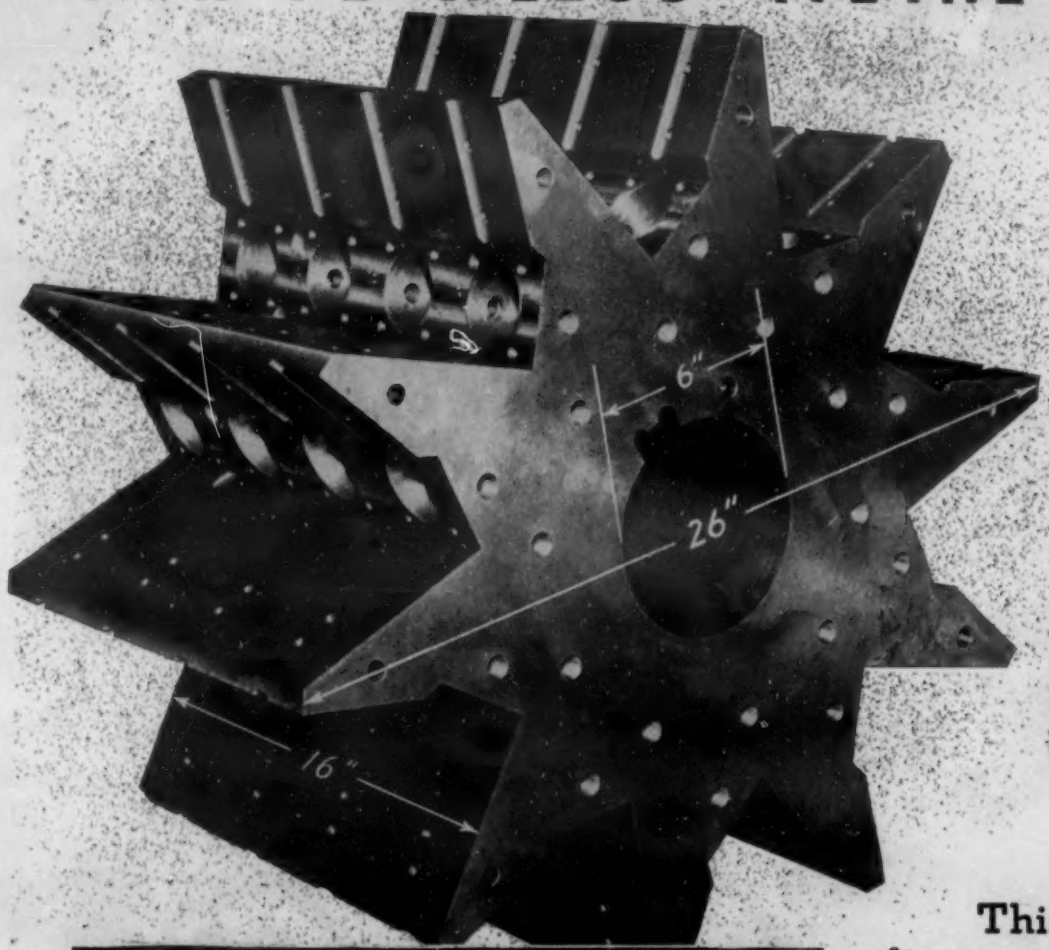
Welded Oil Well Casing

Welded oil well casing installed in the well costs less than similar threaded-and-coupled casing. If all the 100,000,000 feet of casing run per year were welded instead of mechanically joined, it is figured that this would produce a saving of over $5,000,000 to the petroleum industry, or a half-cent per barrel in the total cost of oil production. In addition, a joint efficiency of 100% is easily secured by welding on casing up to and including Grade C, whereas the average joint efficiency of threaded-and-coupled casing does not exceed 60%. With welded casing, the manual operations of making the joints are reduced to utmost simplicity and this added safety feature makes it very popular with drilling crews. Welded casing joints are also of advantage in cementing jobs and less clearance is required between casing strings. It has been predicted that as soon as an efficient casing welding service is developed in all oil fields, the welding of the major portion of all oil well casing will be standard practice (pages MA 282 R 7 and MA 284 R 9).—E. V. D.

Plastics Plus Metals

Hanke (page MA 311 R 7) suggests incorporating magnetic particles into thermoplastics under the influence of a magnetic field so as to orient the particles. On chilling, the particles are retained in their position and impart directional properties. It isn't obvious what such a combination would be good for, but who can tell?—H.W.G.

Sheet and Bar by Direct or Continuous Casting



Outstanding for its thorough and up-to-date treatment is Mort's review (page MA 265 L 5) of processes for the production of sheet, rod, tubing, etc., direct from the molten metal. Progress towards commercial application of any of the existing methods has been slow and discouraging, the problem of controlling the interdependent factors of cooling rate and speed of "draw" still being formidable. However, one large American copper producer is now making continuous-cast billets, so the outlook for important application of this art may not be completely dark.—F.P.P.

Graphite-Copper Castings

Difficulties in producing self-lubricating bearings of the graphitic bronze or graphitic copper types by ordinary melting methods have been so great that best American practice has depended on powder metallurgy for making such composites. Comes now a German method (page MA 269 R 9) that comprises melting the copper with 20-25 per cent graphite in a high frequency furnace to provide thorough mixing, and pouring into metal molds to obtain quick freezing and avoid segregation. The impact properties are still suspect, but the idea sounds interesting anyway.—F.P.P.

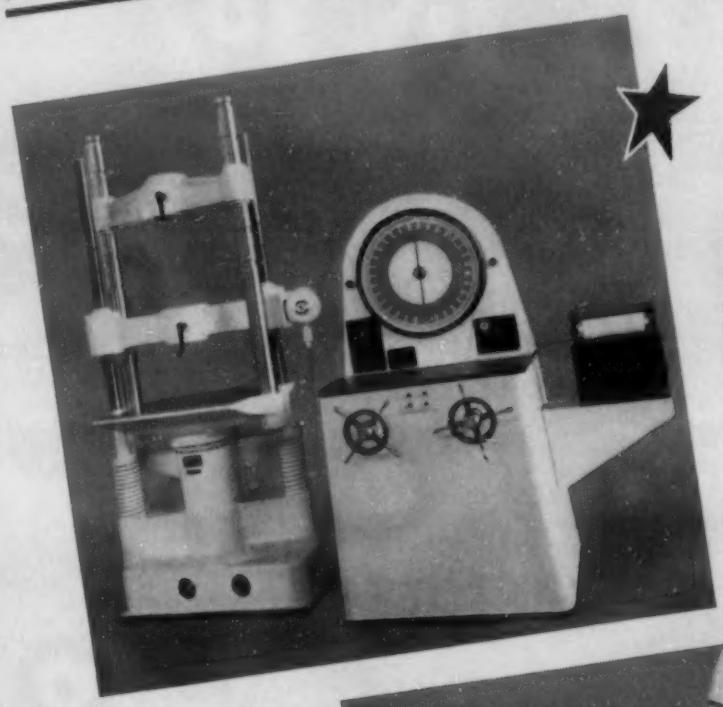
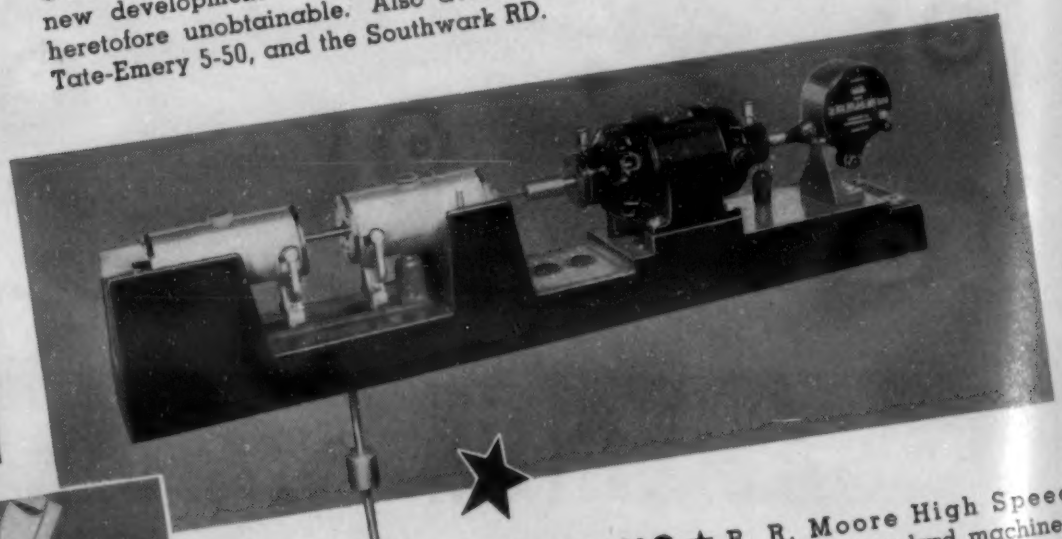
PREVIEW

of the Forty-Second Annual Convention of the



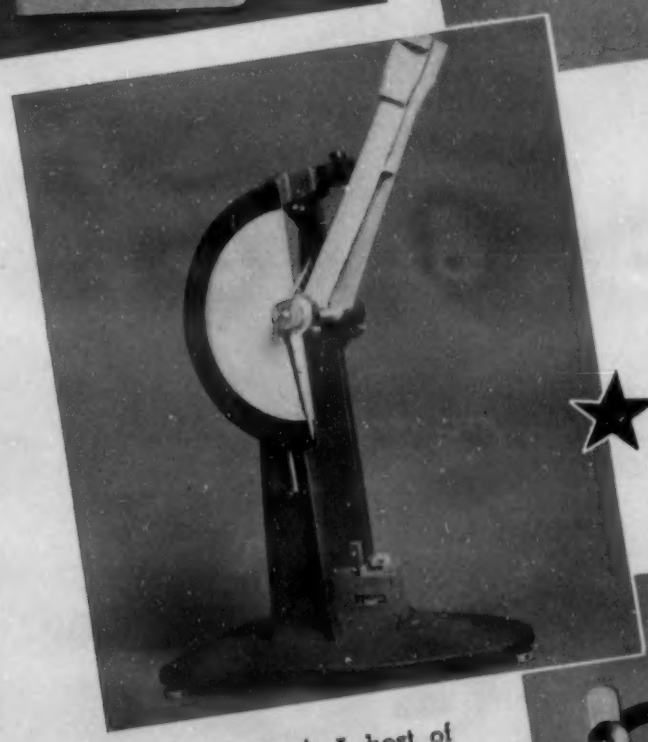
AMERICAN SOCIETY FOR TESTING MATERIALS

Atlantic City, N. J.



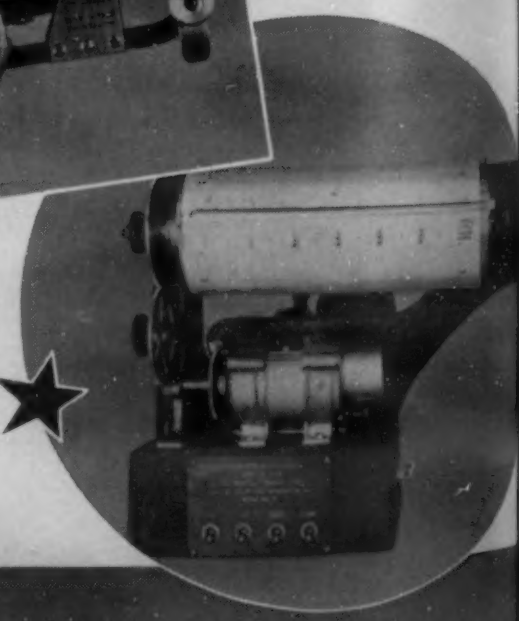
JUNE 26 to 30, 1939

5 STAR COVERAGE



OF YOUR PHYSICAL TESTING EQUIPMENT REQUIREMENTS

STATIC ★ The Southwark-Tate-Emery testing machine—a completely new development in load indication with performance characteristics heretofore unobtainable. Also available are the Southwark-Emery, the Tate-Emery 5-50, and the Southwark RD.



DYNAMIC ★ R. R. Moore High Speed Fatigue Machine for testing standard machined specimens at 10,000 rpm; Rayflex—for electro dynamic fatigue tests of unmachined bars in full section; Bernhard Oscillator for fatigue testing of full sized structures.

IMPACT ★ A notched bar machine of unexcelled precision designed for testing materials requiring low energy to fracture. Also available is the Carpenter Torsion Impact machine for evaluating hard and brittle materials.

STRAIN MEASURING ★ A host of various types of strain measuring devices for analysis of structures under static and live loads. These include such well known types as Huggenberger, Whittemore, de Forest, Carbon Resistor Telemeter and Inductor Telemeter.

STRESS-STRAIN RECORDING ★ The Southwark-Templin high magnification recorder which automatically plots complete test records at full testing speed with such precision and ease that they are used on a routine basis.

SOUTHWARK · EMERY TESTING MACHINES

Baldwin-Southwark Corporation, Southwark Division, Philadelphia; Pacific Coast Representative, The Pelton Water Wheel Co., San Francisco

Introduction

The 42nd annual meeting of the American Society for Testing Materials—always an outstanding technical gathering for all interested in engineering materials—is to be held at Chalfonte-Haddon Hall, Atlantic City, June 26 to 30.

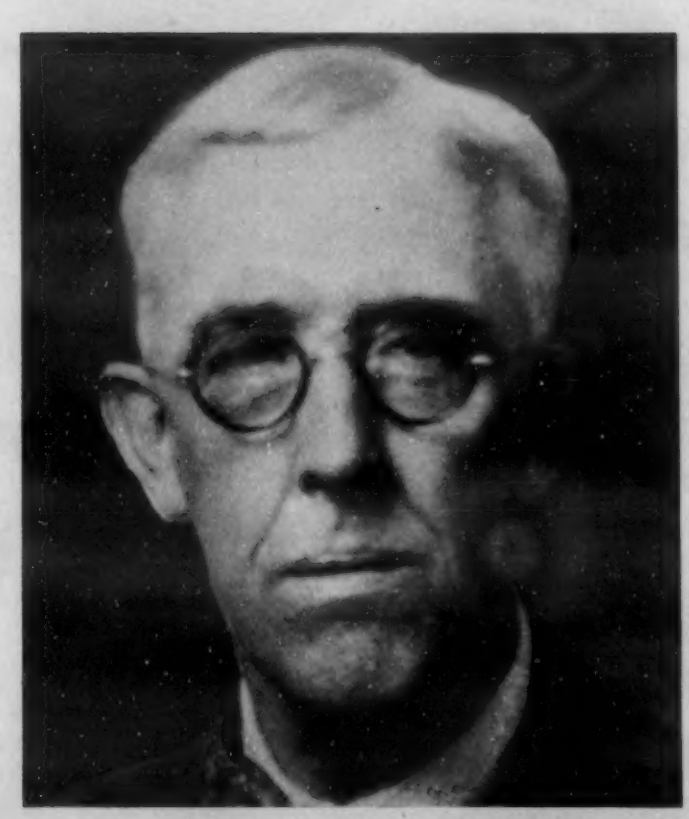
A number of rather significant items of interest will characterize this year's convention. One is that it will be the first meeting in Atlantic City, accompanied by an Exhibit of Testing Apparatus and Related Equipment. Further details of this are given in another page.

Another item of interest, pointed to by The Society, is the unusual number of round table discussions and Symposiums. One of special interest is a round table discussion on "Quantitative Spectrography," scheduled for the morning, afternoon and evening, June 29. Mention should also be made of the one on "Effect of Sub-Atmospheric Temperatures on the Properties of Metals."

The opening session—Tuesday, June 27, 10:30 A.M.—will be featured by the annual address by the President of the Society, and the recognition of the 40-yr. members.

The Edgar Marburg Lecture, the 14th, will be delivered on Wednesday, June 28, at 4 p.m. by Prof. H. F. Moore, University of Illinois, a widely known authority on fatigue and other subjects. His topic this year is "Stress, Strain and Structural Damage."

Following the lecture, the 13th award of the Charles B. Dudley Medal will be made to R. W. Carlson, associate professor of civil engineering, Massachusetts Institute of Technology, for his paper at last year's convention on "Drying Shrinkage of Concrete as Affected by Many Factors."



Including the round-table discussion there will be 23 technical sessions in all. Those relating to metals and the metal industry will be found on other pages.

H. H. Morgan—*President*

G. E. F. Lundell—*Vice President*

H. F. Moore—*Lecturer*

R. W. Carlson—*Medalist*

The Technical Program

The technical sessions commence on Tuesday morning, June 27, and continue through Friday, June 30. On two occasions provision is made for triple simultaneous sessions on topics on which there can be little conflict of interest. This is made necessary to include adequate provision for presentation of all the papers.

The tentative technical program, which only includes sessions devoted to metals and related subjects, follows:

Limited Funds?

HERE'S YOUR MACHINE!

★ Visit Booth 32 at the Atlantic City Meeting of the American Society for Testing Materials . . . Week of June 21st. See for yourself the compactness and rugged construction of the Olsen L-Type Hydraulic Testing Machine. You'll find it on exhibition there . . . and we welcome your most thorough investigation.

THE OLSEN L-TYPE HYDRAULIC TESTING MACHINE . . . for Foundries, Vocational Schools, Small Colleges, Welding and Specialty Shops! Wherever funds for testing work are limited, this machine provides performance of highest efficiency. It is designed, engineered and built to Tinius Olsen standards throughout . . . and those are standards which have been foremost in the field for 59 years! Built for extreme compactness, it permits fast, accurate work while occupying the minimum of floor space. The price is a boon to cramped budgets. Promote the efficiency of your production with this quality machine! Get the facts! They're yours simply for the asking . . . write today.

Symbol of the finest in Testing and Balancing Machines . . . since 1880

Features

OF THE OLSEN L-TYPE HYDRAULIC TESTING MACHINE:

1. **20,000 TO 60,000 LB. CAPACITY.** Overall height, 63½". Floor space, 10 sq ft. Approximate net weight, 2,000 lbs.
2. **INDICATING GAUGES IN INSTRUMENT PANEL.** Isolated from loading cylinder.
3. **CYLINDER IN BASE.** Lowers center of gravity.
4. **CONSTANT SPEED, GEAR-TYPE PUMP.** Quiet and efficient. No pulsation.
5. **DIRECT FLEXIBLE COUPLING CONNECTION OF MOTOR TO PUMP.** Eliminates noise and drive slippage.
6. **PUSH BUTTON STARTERS.** Standard equipment.
7. **FOUR COLUMN RODS.** Makes sturdy construction.
8. **CROSSHEAD ADJUSTING CRANK.** Easy to reach.
9. **STURDY OIL RESERVOIR.** Bolted to base directly under pump.
10. **SEPARATE CONTROLS FOR LOADING AND UNLOADING.**

Tuesday, June 27
Afternoon Session

Subject—Iron

Report of Committee A-2 on Wrought Iron, by C. B. Bryant, Chairman.

Report of Committee A-3 on Cast Iron, by W. H. Rother, Chairman.

"Mechanical Properties of High-Strength Cast Iron," by Jasper O. Draffin and W. Leighton Collins, University of Illinois.

"Influence of Chromium on the Oxidation Resistance of Cast Iron," by Charles O. Burgess, Union Carbide & Carbon Research Laboratories, Inc.

Report of Committee A-7 on Malleable-Iron Castings, by E. K. Smith, Chairman.

"The Resistance of High-Silicon Malleable Iron to Drilling," by H. A. Schwartz, National Malleable & Steel Castings Co., R. C. Kasper and N. E. Mertz, Case School of Applied Science.

"The Relation of Carbon Nodule Size and Tensile Properties of Malleable Cast Iron," by H. A. Schwartz, National Malleable and Steel Castings Co., H. J. Schindler and J. F. Elliott, Case School of Applied Science.

Report of Sectional Committee A-21 on Specifications for Cast-Iron Pipe and Special Castings, by T. H. Wiggin, Chairman.

Tuesday, June 27
Evening Session

Round-Table Discussion of Effect of Sub-Atmospheric Temperatures on the Properties of Metals

"Sub-Size Charpy Relationships at Sub-Zero Temperatures," by H. Habart and W. J. Herge, National Tube Co.

"Factors Affecting Notched-Bar Impact Tests of Steel at Low Temperatures," by Walter Crafts and John J. Egan, Union Carbide & Carbon Research Laboratories, Inc.

Wednesday, June 28
Morning Session

Subject—Fatigue, Corrosion

Report of Research Committee on Fatigue of Metals, by H. F. Moore, Chairman.

"Fatigue Tests of Wire," by C. P. Wampler, A. O. Smith Corp. (Formerly University of Illinois), and N. J. Alleman, University of Illinois.

"Fatigue Strength of Machined Forgings 6 to 7 in. in Diameter," by O. J. Horger and H. R. Neifert, The Timken Roller Bearing Co.

"Fatigue Machines for Testing Structural Units," by R. L. Templin, Aluminum Co. of America.

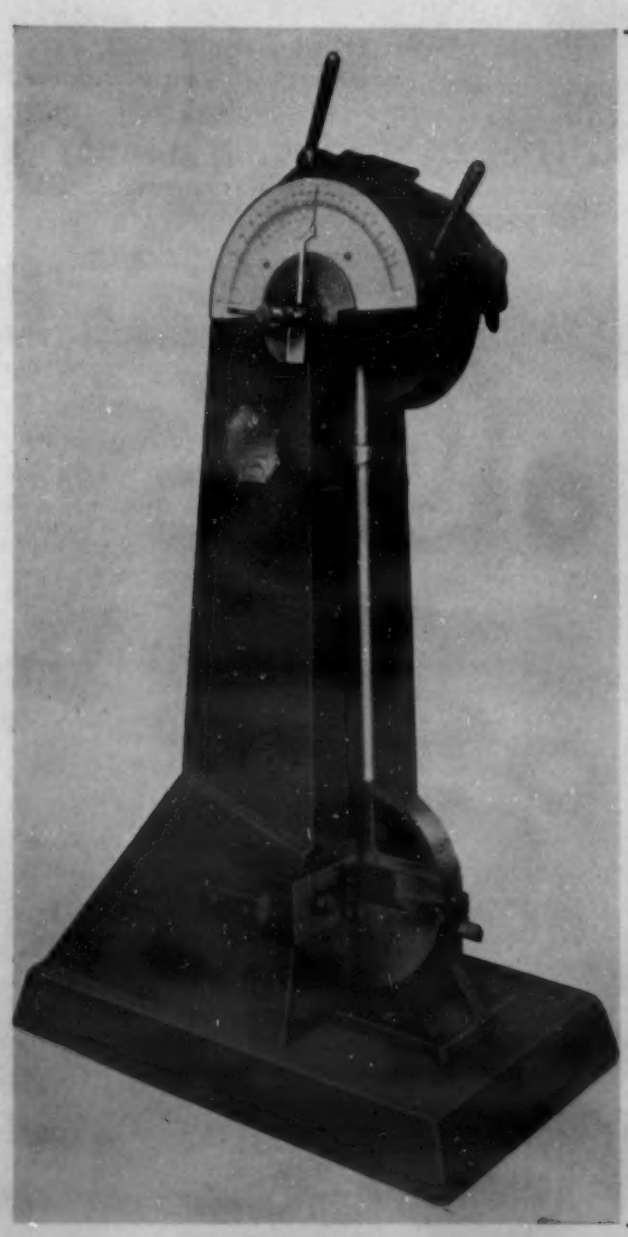
Report of Committee A-5 on Corrosion of Iron and Steel, by W. H. Finkeldey, Chairman.

Report of Committee B-3 on Corrosion of Non-Ferrous Metals and Alloys, by T. S. Fuller, Chairman.

Paper Appended:

"Chemical Removal of Corrosion Products in the Determination of the Corrosion Rate of Zinc," by E. A. Anderson and C. E. Reinhard, The New Jersey Zinc Co.

"Atmospheric Corrosion of Non-Ferrous Metals and Alloys," by C. W. Borgmann, University of Colorado.



Report of Joint Committee on Exposure Tests of Plating on the Non-Ferrous Metals, by William Blum, Chairman.

Wednesday, June 28
Afternoon Session

Subject—Lecture and Award of Medal

Fourteenth Edgar Marburg Lecture: *'Stress, Strain and Structural Damage,"* by Prof. H. F. Moore.

The Machine That Made
Impact Testing Popular

Riehle Precision Combination
Izod–Charpy–Tension
Impact Tester

Nearly Sixty Sold During Past Few Years

RIEHLE TESTING MACHINE DIVISION
American Machine and Metals Inc.
EAST MOLINE, ILLINOIS

ASTM Exhibit Booth Number 18

It Gives a Picture of the Wire

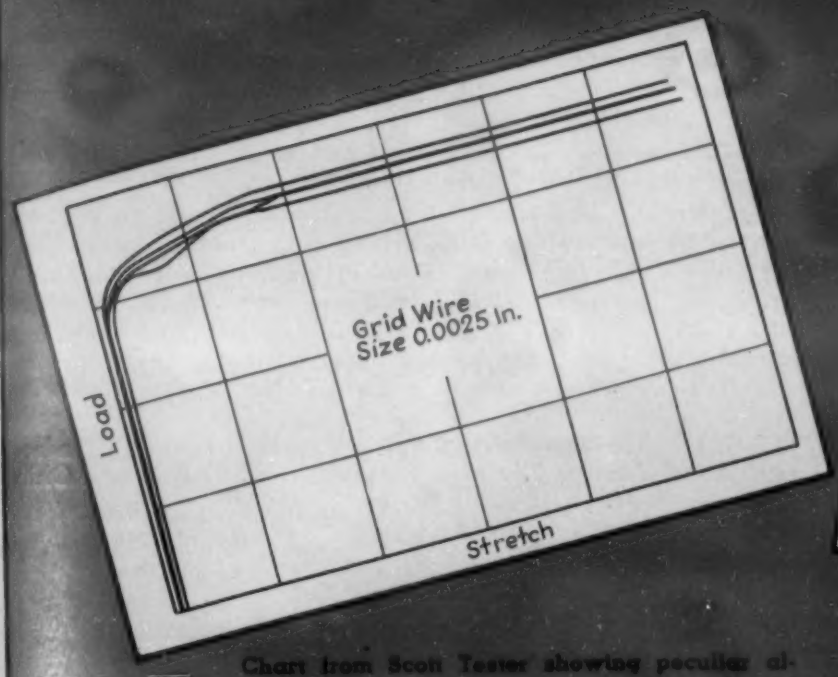

Chart from Scott Tester showing peculiar alternating characteristics of good ratio grid wire beyond yield point.

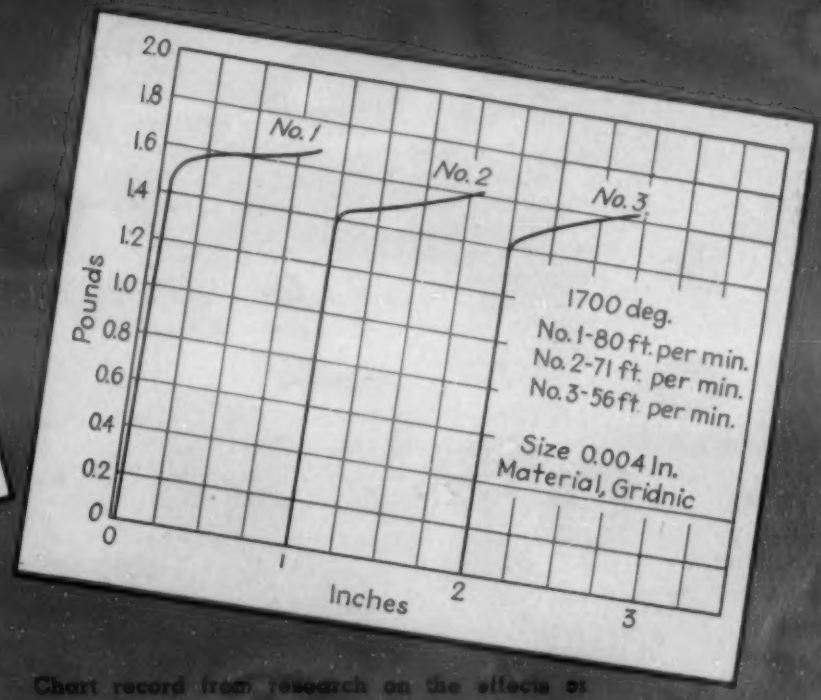

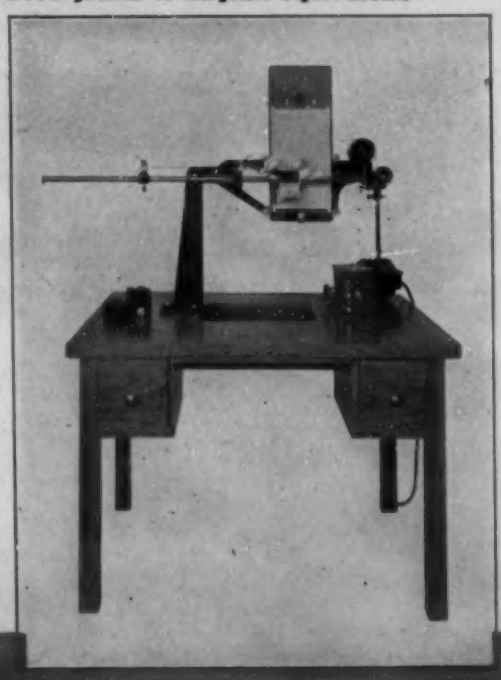

Chart record from research on the effects of conveyor speeds during heat-treatment of special-purpose wire.

Scott Incline Plane Serigraph Automatically Records Entire Action of Wire Under Test.

The Scott Incline Plane Serigraph will test tensile and elongation, hysteresis or fatigue at any predetermined point of load for any number of repeated cycles, and the test may be carried to breaking at any time desired. It produces a permanent chart-record of elongation, recovery, permanent loss, yield strength, ultimate tensile strength—of every phase of the testing.

The machine is sufficiently delicate for research testing, yet is substantial enough to withstand the wear and tear of daily routine work. For instance, the inclined plane—the heart of the machine—is of hardened stainless steel, polished to a mirror finish, and the wheels of the testing carriage are mounted on sapphire jewel bearings which operate with the least possible amount of friction. The Scott Tester is so simple to operate that accurate, dependable results may be obtained by ordinary operators.

(Below)—Scott Incline Plane Serigraph IP2. Furnished in capacities from 25 to 2000 grams or English equivalent.

Many manufacturers are now using Scott Testers to get a complete "picture" of the wire they make and use for fabric, screens, filter cloth, brake bands, and many other purposes. For further details, send for a reprint of an article just published in "Metals and Alloys."

Award of Charles B. Dudley Medal to Roy W. Carlson, Massachusetts Institute of Technology.

Wednesday, June 28
Evening Session

Subject—Radiography, Magnetic Testing, Metallography

Report of Committee E-4 on Metallography, by L. L. Wyman, Chairman.

Paper Appended:

"Application of Color Photography to Metallographic Work," by R. P. Loveland, Eastman Kodak Co.

Report of Committee E-7 on Radiographic Testing, by H. H. Lester, Chairman.

"The Use of Radiography in the Development of Castings for Mass Production," by Don M. McCutcheon, Ford Motor Co.

"Factors Governing Practical Sensitivity of Radiographic Tests," by H. H. Lester, Watertown Arsenal.

Modern Testing of Aircraft Materials:

"Correlation of Some Mechanical Tests of Aluminum Alloys with X-ray Tests," by Tom A. Triplett, Triplett & Barton, Inc., and W. Lavern Howland, California Institute of Technology.

"Some Mechanical Tests of Aluminum Alloys 14ST and 24ST," by W. B. Mechling and S. S. Jack, California Institute of Technology.

Report of Committee A-6 on Magnetic Properties, by Thomas Spooner, Chairman.

"Magnetic Analysis—Modern Methods and Applications," by Theodor Zuschlag, Magnetic Analysis Corp.

Thursday, June 29
Morning Session

Subject—Steel Ferro-Alloys, Effect of Temperature

Report of Committee A-1 on Steel, by N. L. Mochel, Chairman.

"The Work-Brittleness Test," by H. W. Graham, Jones & Laughlin Steel Corp., American Iron and Steel Works..

Report of Committee A-10 on Iron-Chromium, Iron-Chromium-Nickel and Related Alloys, by Jerome Strauss, Chairman.

"The Alloy Casting Research Institute Test Block for Heat-Resisting Alloys; Its History, Selection and Utilization," by O. E. Harder, Battelle Memorial Institute.

"The Hastelloy Alloys, Their Physical and Corrosion-Resistant Properties," by F. G. McCurdy, Haynes Stellite Co.

Report of Sectional Committee B-36 on Standardization of Dimensions and Materials of Wrought-Iron and Wrought-Steel Pipe and Tubing, by H. H. Morgan, Chairman.

Report of Committee A-9 on Ferro-Alloys, by Charles McKnight, Chairman.

Report of Joint Research Committee of A.S.M.E. and A.S.T.M. on Effect of Temperature on the Properties of Metals, by N. L. Mochel, Chairman.

Thursday, June 29
Morning Session

Round Table—Spectrography

Round-Table Discussion on Quantitative Spectrography
(To continue during the afternoon and evening.)

Thursday, June 29
Evening Session

Subject—Methods of Testing

Report of Committee E-1 on Methods of Testing, by W. H. Fulweiler, Chairman.

Paper Appended:

"Testing of Hydrometers," by E. N. Hurlburt, Taylor Instrument Cos.

Report of Sectional Committee Z-23 on Specifications for Sieves for Testing Purposes, by L. T. Work, Chairman.

"Tension Specimen Shape and Apparent Strength," by F. G. Anderegg, Owens-Corning Fiberglas, Royal Weller and B. Fried, Ohio State University.

"Rockwell Hardness of Cylindrical Specimens," by W. E. Ingerson, Bell Telephone Laboratories, Inc.

"Analysis of Rockwell Hardness Data," by R. L. Peek, Jr., and W. E. Ingerson, Bell Telephone Laboratories, Inc.

"Stress-Strain-Time Characteristics of Materials," by Glenn Murphy, Iowa State College.

"A Study of the Influence of Speed on the Torsion Impact Test," by O. V. Greene and R. D. Stout, The Carpenter Steel Co.

"Load Weighing and Load Indicating Systems, an Historical Account of Their Development with Particular Reference to Materials Testing Devices," by Chester H. Gibbons, Baldwin-Southwark Corp.

"Photoelastic Analysis of a Prestressed Beam," by F. O. Anderegg, Owens-Corning Fiberglas, Royal Weller and B. Fried, Ohio State University.

Friday, June 30
Afternoon Session

Subject—Non-Ferrous Metals

Report of Committee B-1 on Copper and Copper-Alloy Wires for Electrical Conductors, by J. H. Foote, chairman.

Report of Committee B-2 on Non-Ferrous Metals and Alloys, by E. E. Thum, Secretary.

Report of Committee B-5 on Copper and Copper Alloys, Cast and Wrought, by C. H. Greenall, Chairman.

Paper Appended:

"Nomenclature and Classification of Cast Copper and Copper-Base Alloys," by Sam Tour, Lucius Pitkin, Inc.

"Service and Life of Non-Ferrous Tubes in Petroleum Refining," by E. S. Dixon, The Texas Company.

Report of Committee B-6 on Die-Cast Metals and Alloys, by J. R. Townsend, Chairman.

Paper Appended:

"Magnesium Alloy Die Castings," by A. W. Winston, The Dow Chemical Co.

Report of Committee B-7 on Light Metals and Alloys, Cast and Wrought, by Sam Tour, Chairman.

Report of Committee B-4 on Electrical-Heating, Electrical-Resistance and Electric-Furnace Alloys, by Dean Harvey, Chairman.

'Spectral Emissivity (at 0.65μ) of Some Alloys for Electrical Heating Elements," by W. F. Roeser, National Bureau of Standards.

Report of Committee E-2 on Spectrographic Analysis, by H. V. Churchill, Chairman.

"The Spectrographic Analysis of Tin," by J. Warren Stewart, Carnegie Institute of Technology.

THE EXHIBITION

It is the custom of the A.S.T.M. to hold an exhibition of testing apparatus and related equipment every other year. The last one—one of the most successful ever held—was in June, 1937, at the annual convention at the Waldorf-Astoria Hotel in New York.

The one this year—the fifth—will occupy the Vernon and Garden Rooms in the Haddon Hall at Atlantic City. It will be

located close to the registration desks and members' lounge which is just outside these two rooms.

Previous exhibits have featured two special types of displays which are considered extremely valuable and which have been highly recommended—those sponsored by committees of the Society portraying various phases of their standardization and research work, and, second, displays of institutional, research and Governmental laboratories of special fabrication and technique. They are visited by many attending the convention.

One other development is of interest—a photographic exhibit and competition on the theme, "Testing and Research in Engineering Materials." The first one of this character was held in 1938 and its success has merited a repetition this year.

The official opening of the Exhibit will be noon, Monday, June 26.

A partial list of the exhibitors follows:

American Instrument Co.
Washington, D. C.

Baldwin-Southwark Corp.
Philadelphia, Pa.

Bausch & Lomb Optical Co.
Rochester, N. Y.

Christian Becker, Inc.
New York City

Brabender Corp.
Rochelle Park, N. J.

Central Scientific Co.
Chicago, Ill.

Eimer & Amend, Inc.
New York City

The Electric Tachometer Corp.
Philadelphia, Pa.

Federal Products Corp.
Providence, R. I.

Henry A. Gardner Laboratory
Washington, D. C.

Kimble Glass Co., Vineland, N. J.

Leeds & Northrup Co.
Philadelphia, Pa.

"Metals and Alloys"
New York City

National Carbon Co., Inc.
Cleveland, Ohio

Nurnberg Thermometer Co., Inc.
Brooklyn, N. Y.

Tinius Olsen Testing Machine Co.
Philadelphia, Pa.

Parr Instrument Co., Moline, Ill.

E. W. Pike & Co.
Elizabeth, N. J.

Radium Chemical Co., Inc.
New York City

Riehle Testing Machine Division,
American Machine and Metals, Inc.....East Moline, Ill.

Rubicon Co.....Philadelphia, Pa.

George Scherr Co., Inc.
New York City

Henry L. Scott Co., Inc.
Providence, R. I.

C. J. Tagliabue Manufacturing Co.....Brooklyn, N. Y.

Carl Zeiss, Inc...New York City

BUSCH METAPHOT

On Demonstration
at Booth 23

Also on exhibit: Bore Inspection Telescope for internal inspection

Comparison Microscope for surface finish

Equipment for the preparation of metallographic specimens. Write for complete literature on these articles.

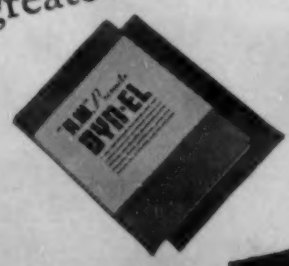
GEORGE SCHERR CO.
124 LAFAYETTE ST., NEW YORK

ZEISS

The Zeiss "Neophot" Metallograph is a universal apparatus for micro- and macro-photography, low power survey, bright field and dark field work with instantaneous change-over without disturbance of focus, and for use of polarized light to examine medium polished surfaces under high magnification. Simple yet stable design. Unexcelled optics. Easy to operate. Catalog MICRO 500-A156 upon request.

You are cordially invited to visit our Exhibit at the ASTM Convention at Atlantic City, Booths 16 & 17.

CARL ZEISS, INC., 485 FIFTH AVE., NEW YORK
728 So. Hill St., Los Angeles



"NEOPHOT" METALLOGRAPH

New Bus Cuts Dead Weight 1300 pounds

25-passenger bus built by BOYERTOWN AUTO BODY WORKS, Boyertown, Pa. Over-all length, bumper to bumper, approximately 25'; over-all width, 96". All structural sections are 18 gage Dyn-el.

With rolled structural sections of conventional steel, this 25-passenger bus would have a curb weight of 10,000 pounds. With formed structural sections of "A. W." Dyn-el, the curb weight is only 8,700 pounds—a saving of 1,300 pounds in dead weight . . . And with all its lightness this body of "A. W." Dyn-el high strength steel is stronger than a conventional body, and has greater resistance to shock, fatigue and corrosion.

The 48-page book, "A.W." Presents Dyn-el, gives full details of savings in weight and cost possible with this new high-strength, flat-rolled steel. Diagrams, tables and charts cover a wide range of tests and properties. To executives, this book gives a quick picture of performance and costs. To engineers, it gives complete fabricating and design properties and table of sizes and weights. We will be pleased to send you a copy.

DYN-EL

ALAN WOOD STEEL COMPANY

MAIN OFFICE AND MILLS, CONSHOHOCKEN, PENNA. : : SINCE 1826 : : DISTRICT OFFICES AND REPRESENTATIVES—Philadelphia, New York, Boston, Detroit, Los Angeles, Seattle, San Francisco, Houston, Roanoke, Buffalo, Pittsburgh, Cleveland, Chicago, Cincinnati, New Orleans, St. Paul, St. Louis, Montreal. PRODUCTS INCLUDE—"A. W." Rolled Steel Floor Plate : : "Swede" Pig Iron : : Billets—Blooms and Slabs : : Sheared Steel Plates : : Hot Rolled Sheets and Strip : : Steel Products also furnished in Copper and Alloy analyses.

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Wear of Cast Iron

West and Hodgson (page MA 369 L 1) state that high P helps wear resistance, while Francis (page MA 369 R 2) says that a phosphide eutectic is very bad, since particles pull out to form a hard abrasive. Isn't it all a question of whether the service is such that the debris is trapped between mating surfaces?—H.W.G.

Quicker Than the Eye

Andrew (page MA 335 R 4) suggests that the graphitizing action of Ni is due to an unstable Ni carbide which breaks down. This is the sort of hypothesis that is hard to disprove, since its promulgator can postulate such a high degree of instability that its presence can't be caught by any sort of quench, so examination would have to be at the high postulated temperature of formation.—H. W. G.

Oxides

Elliss (page MA 336 R 1) alleges that yield strength is enhanced by presence of oxygen in steel, as he drops the yield strength by vacuum melting.—H.W.G.

Grain Size

Houdremont and Schrader (page MA 342 R 8) offer evidence that AlN plays a part in grain size control by Al. —H.W.G.

Cold-Rolled Malleable Iron

Improving the mechanical properties of malleable Fe by cold-rolling is said to be one result of an English investigator (page MA 339 L 9). White heart malleable is cold-rolled with light passes and proper annealing. Some useful industrial applications are claimed.—E.F.C.

High Frequency Heat Treatment

In newly developed German equipment for selective hardening of crankshafts by high frequency heat (page MA 344 R 3) 40 small crankshafts with 8 bearings each are treated per hr. Time for heating is 4 sec. and for quenching, 8 sec. Another one for large crankshafts is in operation.—E.F.C.

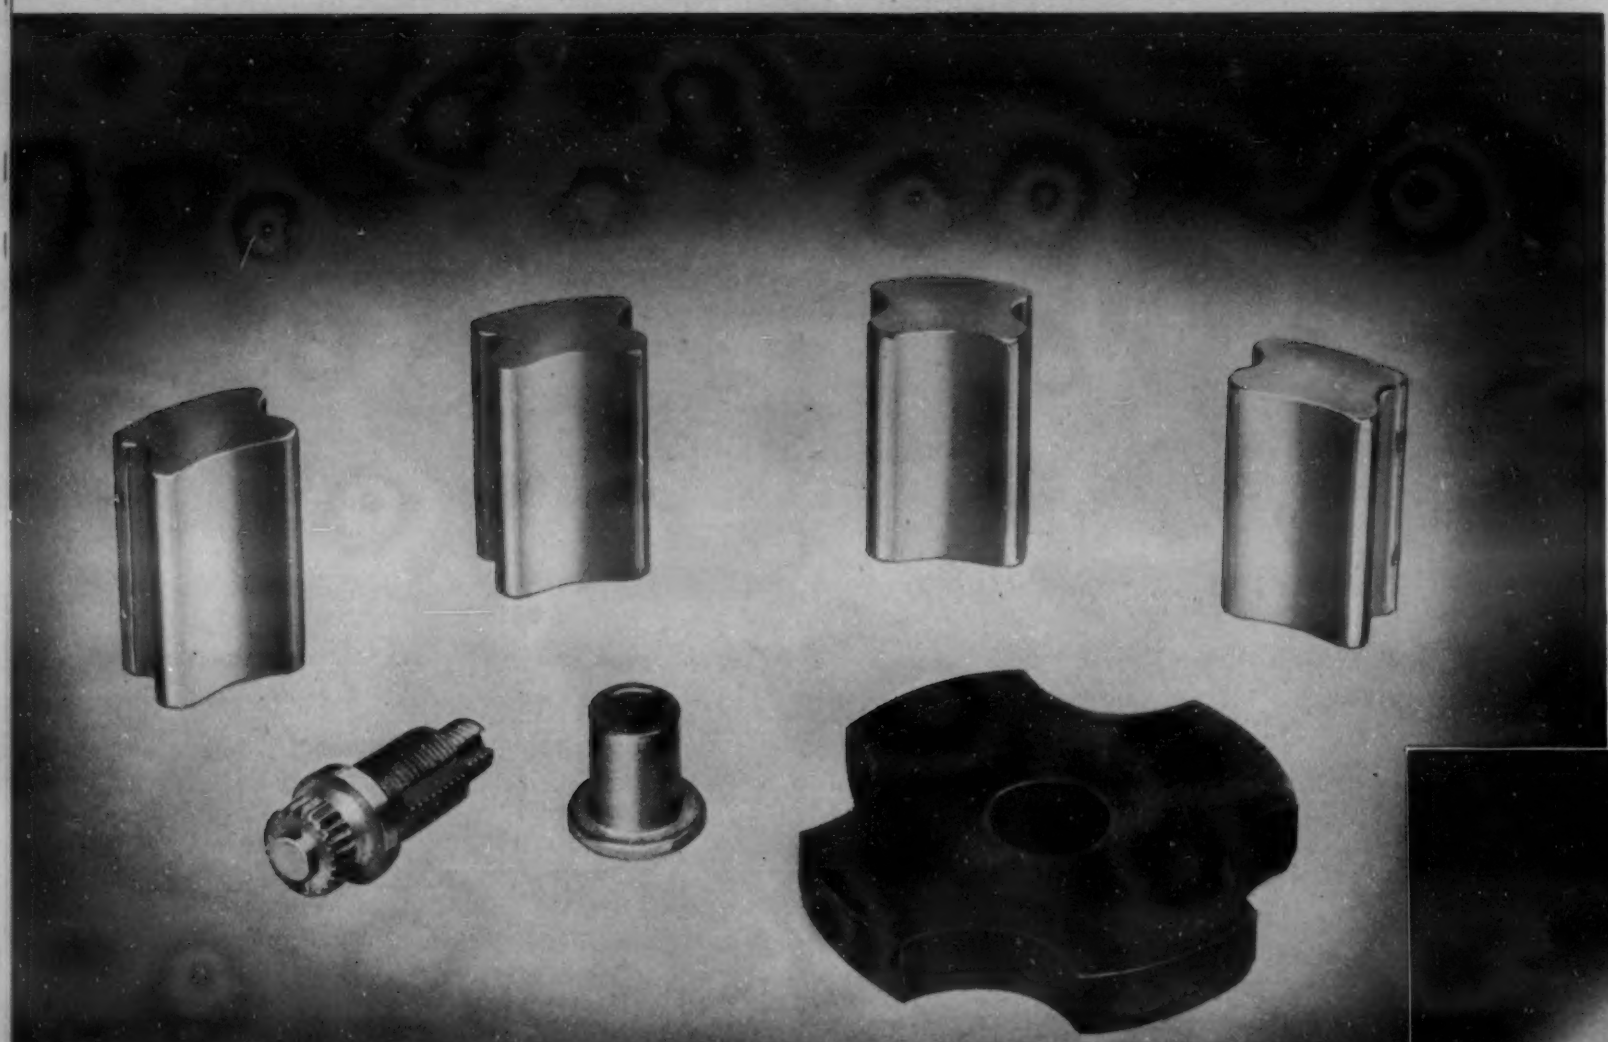
Welding of Aluminum

Welding provides an efficient means of making permanent leakproof joints and repairs on aluminum and aluminum alloy products. Fusion welding, in the form of torch and arc welding, and pressure welding in the form of spot, butt and seam welding are all used for these materials. Oxyhydrogen and oxyacetylene welding are more widely used than any other method. These processes are simple and rapid and can be applied to metal of any thickness.

The major developments in resistance welding of aluminum and its alloys have taken place just within the past few years. Nevertheless, it has already become an important fabricating process. In many cases, it has brought about reduced cost, high production and an improved product. Undoubtedly its use will continue to grow in the future (page MA 354 R 5).—E.V.D.

Lead and the Hardening Depth of Chilled Iron

The hardening depth of cast iron is changed by the presence of Pb, according to H. Bruhn, a German investigator (page MA 335 R 7). This was discovered by chance in a roll foundry. Because of contrary results, depending on the melting medium, the research was undertaken. The cause of the different effects of Pb is believed to lie in the residues present in iron, such as oxides and alloying elements.—E.F.C.



High Tensile Steels Lead

According to a survey (page MA 367 R 5) of the specific strength (strength divided by sp. gr.) of materials for aircraft, the low alloy, high tensile steels lead with elektron and duralumin a close second.—E.F.C.

German Wide Strip Mill

The Germans have developed a 2-pass universal rolling mill for rolling wide strip semi-continuously (page MA 339 L 8). The strip is returned by rollers for the return pass through the same 3-high universal stand which has at each side of it an auxiliary 2-high stand. Smaller initial and operating cost, less space than the usual continuous tandem mill, with easy accommodation to change in production rate are claimed.—E.F.C.

ZINC ALLOY DIE CASTINGS

7 PARTS
—CAST INTO 1

Assembly costs are greatly minimized with ZINC Alloy Die Castings—regardless of the complexity of design. But there are many instances where it is essential to assemble more than one metallic element in a single unit. Consider the economies of the above application where 7 inserts, having special properties, are cast into 1 piece.

1. ASSEMBLING—The magneto generator part (smaller photograph) calls for 4 pole pieces of soft steel, an aluminum-nickel disk, a bronze bushing, and a steel support stud. These elements (larger photograph) are inserted in the die casting die and a ZINC Alloy housing is cast around them. The result: 1 piece instead of 7.

2. MACHINING — Although the inserted elements require finishing beforehand, there is no machining done on the ZINC Alloy Die Cast housing itself, other than the simple tapping of holes.

3. ACCURACY—With the die casting process it is possible to place each insert accurately in its correct relative position in the housing. And the physical properties of the ZINC Alloys are such that ample strength and permanence are insured in the securely anchored complete unit.

The utilization of a wide selection of insert materials, having special properties, is just one of the many advantages of ZINC Alloy Die Castings. For further information we suggest that you consult a commercial die caster—or write to

HORSE HEAD SPECIAL (99.99+% UNIFORM QUALITY) ZIN

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Metallic Shielded Arc Electrode Coatings

The principal feature of the electrodes used in shielded arc welding is their heavy coating or flux covering, which acts to: (1) Form a protruding flux sheath at the electrode tip, mechanically shielding and exerting a directional control upon the arc. This is due to a lag in the consumption of the coating over that of the core metal. (2) Produce an inert or reducing atmosphere, enveloping the arc and weld metal. This results from the volatilization, dissociation and combustion of various coating constituents. (3) Provide a protective slag covering over the weld surface, obtained by the melting and reaction of the less volatile mineral ingredients of the coating.

As indicated in the abstract, (page MA 424 L 4), the ingredients used in compounding electrode coatings, of which the shielded arc type form the most important group, are exceedingly numerous and varied. The characteristics of any coated electrode are almost entirely dependent upon the combination of materials employed in the coating.—E. V. D.

Annealing and Radiant Tube Heating Have the Stage

Of the last batch of abstracts received, a number of them deal with annealing. James E. Dare (page MA 412 L 5) tells about the application of the luminous flame; Ralph M. Drews (page MA 416 R 7) controls the microstructures in high-carbon and alloy steel bolts by annealing in a bell-type furnace heated by radiant tubes: J. L. Whitten (page MA 414 R 5) features annealing strip in coils in a bell-type furnace using radiant tubes; and W. F. Ross (page MA 416 R 4) describes continuous strand annealing of cold-rolled strip in an electrically heated furnace.—O. E. H.

Cracking Tubes

Jamison (page MA 449 R 2) says that modern 18:8 cracking tubes in oil refineries are never corroded, and do not fail by sudden rupture. Some of the early tubes did so fail when they were first tried and gave 18:8 a black eye.—H. W. G.

Protective Coating for Al-rivets for Stainless

The English have been partial to lanoline coatings for protection of Al on aircraft. An improved one, in which the lanolin is hardened by resin, is mentioned by Sidery and Willstrop (page MA 449 L 5). They advocate what one might call a high Ni brass, 45 Ni, 30 Cu, 23 Zn (even though these percentages don't add up to 100, this is the composition given in the original article) for rivets for joining stainless steel.—H. W. G.

Intellectual Curiosity

Pearson (page MA 450 L 1) cites satisfying the intellectual curiosity of pipe-line technologists, as one virtue of soil survey methods, among other more utilitarian virtues.—H. W. G.

Static Electricity

Skinner (page MA 450 L 8) advances the hypothesis that static electricity can be present on shipboard and that this may have something to do with corrosion of ship plates. Evidently one needs to be careful about stroking the ship's cat.—H. W. G.

Quantity Production

Kostron (page MA 433 R 1) describes a method for studying age hardening in which an apparatus automatically forces a Brinell ball into the specimen at predetermined intervals, leaving impressions that the investigator may measure at his leisure.—H. W. G.

Electric-Furnace Brazing

The electric-furnace brazing process consists of uniting assemblies with brazing metal in an electric furnace containing a reducing atmosphere. The brazing metal is usually in the form of a Cu-wire, applied near the joints to be brazed. In the furnace, the metals are freed from oxides and thus prepared for wetting by the molten brazing metal.

Like other well-testablished methods of fabricating or forming metal assemblies or parts, electric-furnace brazing has a definite field in which it is supreme. This applies particularly to work where the volume of production is sufficient to justify the investment in equipment involved. In such cases, marked improvement in quality and reduction in cost of the product have been obtained. There have been many instances where electric-furnace brazing has made possible the development of a new product, which would have been difficult or impossible to make in any other way (page MA 422 R 4).—E. V. D.

ZINC ALLOY DIE CASTINGS

$11.30 SAVED

—By Die Casting This Part

When a well-known coin stamping machine was redesigned recently, the above part—the heart of the machine—was changed to a ZINC Alloy Die Casting. The saving in piece cost over the former "machined" part was $11.30. Consider *all* of the following features of this part as a die casting.

1. ECONOMY—There is no machining required on this casting other than the removal of the gate and tapping of the cored holes. The part illustrated here has received no further machine work. Here is rare complexity of design cast *in one piece.*

2. ACCURACY—The mechanism of the coin stamping machine is such that exceptionally close tolerances are demanded of this part. As a ZINC Alloy Die Casting, dimensions as close as .001" are held—and these dimensions will be the same in the first and last casting of a long production run.

3. STRENGTH—The strength of this casting is superior to that of the former part, yet there is a decided saving in weight. The smaller, rear view photograph shows the elimination of metal by the use of strengthening ribs.

This is not an unusual instance of die casting economy—hundreds of other manufacturers can cite similar savings in their products through the use of die cast parts. Consult any commercial die caster about ZINC Alloy Die Castings—or write to this Company.

HORSE HEAD SPECIAL (99.99+% UNIFORM QUALITY) ZIN

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

All the Abstracts

This highlight is dedicated, for variety, not to an individual abstract but to the whole Abstracts department as it appears this month. We're pardonably proud of it. First, because it represents the practical culmination of efforts to improve the "timeliness" of the service—readers should note the very large proportion of abstracts of articles published in June and July, corresponding to the minimum time-lag that can be achieved in a well-edited abstracts service. And second, because this issue initiates the publication of "composite digests"—several abstracts on the same general topic combined under one head for purposes of correlation (e.g. page MA 558 L 8). If readers approve, we'll continue to run some of these every month, so let's have your reaction.—The EDITORS.

Gas-Heated Cupola

German experiments in burning gas instead of coke to melt the charge are reported (page MA 525 L 9) "very encouraging," justifying further investigation. Construction of such equipment is described.—E. F. C.

Electric Cast Iron

Three methods of making cast iron in electric furnaces are reported to be successful and spreading in use in Germany and elsewhere (page MA 528 R 3). The three methods are: (1) Combination of blast furnace and electric; (2) cupola and electric; and (3) steel and scrap iron in electric furnace with product called "synthetic."—E. F. C.

Resistance Wire

A "composite digest" on wires for electrical applications (page MA 554 L 7) contains lots of dope on resistors, a subject on which useful published information is scarce. Data of interest to both makers and users are especially replete in the paper by Sanford and Harder, and its discussion.—F. P. P.

What is an Alloy Steel?

Portevin (page MA 556 R 4) offers his contribution to the search for a definition of an "alloy steel." It's unlikely that his proposal will be widely accepted, for his "floor under alloy contents" is higher for Cr, Cu, Si or Mo than their actual content in many present-day low alloy, high strength steels.—F. P. P.

[This proposal, if compared with the minimum limits of the American Iron and Steel Institute on page 38 of the Annual Statistical Report for 1938, is strikingly different.—E. F. C.]

Flame Hardening

Sprocket teeth cast from SAE 3135 (Cr-Ni) steel are reported (page MA 534 R 9) flame-hardened satisfactorily. Brinell hardness was held between 500 and 550 on a production basis. The sprockets thus treated run about 5 times longer than untreated sprockets.—E. F. C.

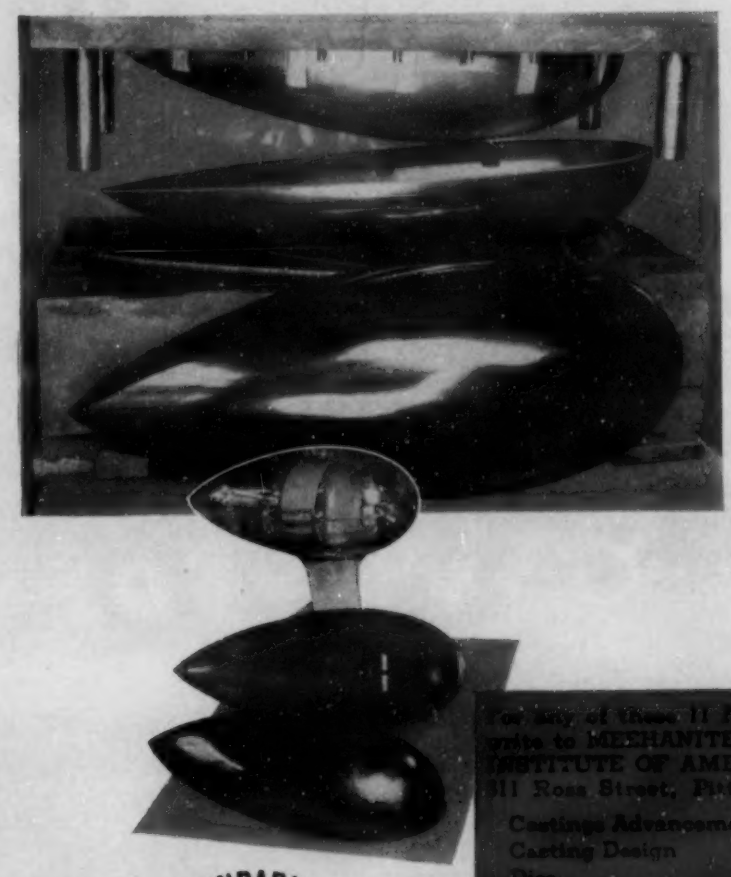
Deep Drawing Tests

Engineers are still seeking methods of evaluating deep-drawability of sheet metal that reasonably simulate operating conditions. Jevons (page MA 548 R 6), most articulate of British writers on this subject, publishes an excellent comprehensive review of the present situation.—F. P. P.

Fatigue of Crankshafts

German attention to (among other things) fatigue problems in automobile crankshafts seems to be intense. Bandow (page MA 550 L 2) stresses the importance of determining fatigue properties under actual operating surface and contour conditions. Cornelius (page MA 550 R 1) agrees that fatigue strength depends on shape more than material, and states that special design may be more effective than application of alloy steels.—F. P. P.

Electric Salt Bath Furnace



In a "new type" of salt bath furnace in Germany, electrodes are arranged on one side only so that current does not flow through the part of the bath containing the steel to be heated. It is said to be suited to case-hardening, Cr-Mo steel especially (page MA 536 L 3).—E. F. C.

FOR SUPERIOR FINISH — LONG LIFE

USE MEEHANITE

CAST-TO-FORM DIES

A user's actual experience is related in this letter. The die performs the unusual and difficult job of forming plastic cases for an aircraft direction finder. The same benefits are available to *you*.

Att: Mr. C. E. Herington, Advertising Manager

Dear Mr. Herington:

The Insulation Mfg. Co. Inc., 11 New York Avenue, Brooklyn, N. Y., moulder of the Lear Aircraft Direction Finder, has asked me to write you on why we selected Meehanite for the die material.

There were three factors that governed this selection:

1. - Speed from blueprint to first production (cavity and channels for heating and chilling were cast direct in the die by the H. W. Butterworth Co., Bethayres, Penna. who worked very closely with us).

2. - Cost (This had to be low because of the experimental nature of this job).

3. - Ease of machining and freedom from defects. (This factor greatly reduced the total estimate and made this job practical from the customer's standpoint).

As you see by the photograph of the finished piece and Insulation Mfg. Company's letter, the die has proven highly satisfactory.

It will no doubt interest you to know also, the die is of "B" grade Meehanite used without heat treatment of any kind except for the tempering of the automatic ejector pins.

Very truly yours,

MECHANICAL DIE & TOOL CO. INC.,

C. Newell Starke

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Open-Hearth for Malleable Iron

Under certain conditions, the open-hearth furnace has advantages in melting malleable cast iron (page MA 582 R 4). It precludes, however, fully mechanized continuous molding, because the supply of metal is intermittent. But such a supply provides a large bulk of uniform analysis with close control of composition.—E. F. C.

Seeing Stresses

Increasing applications of photoelastic stress analysis are emphasized by the number of recent articles on the method and applications of this newest of engineering tools (page MA 611 R 3).—F. P. P.

New Cupola Melting Process

The Germans have developed (page MA 582 L 5) a process for melting the cupola charge by a utilization of the heat of the fuel by radiation rather than by convection, as in the blast furnace. Instead of the heat being transmitted in the counterflow manner of burden and gas, the heat is radiated from a coke layer, heated to a white heat, on top of the burden.—E. F. C.

Aluminum Cable Sheathing

Czempiel and Haase (page MA 620 R 4), urging wider use of aluminum for cable sheathing, offer physical property comparisons between lead, antimonial lead and 2 grades of aluminum. The abstractor suspects wishful thinking, but, nevertheless, aluminum does have certain very definite advantages for this application that merit consideration.—F. P. P.

Cutting Tools

Many users of cutting tools are confronted with the problem as to which tool to use on certain materials. A "composite abstract" (page MA 583 R 9), covering three articles, gives excellent advice, based on experience, on a broad range of materials to be cut and the cutting tools.—E. F. C.

Metals in the Refinery

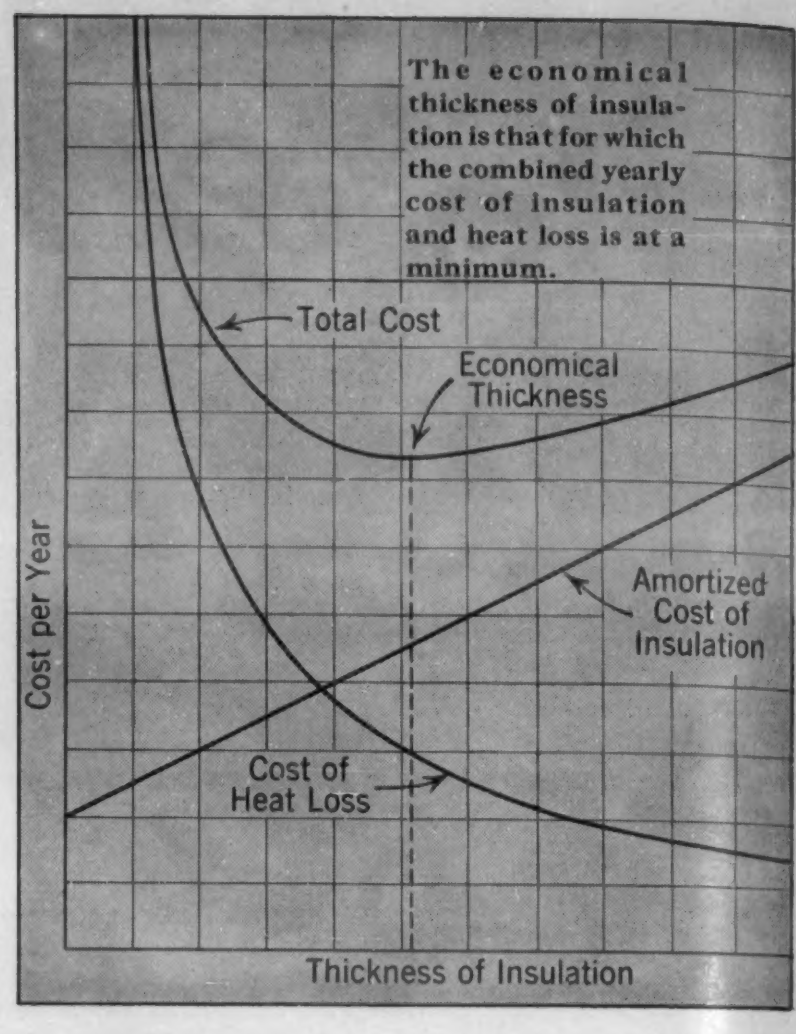
Several recent articles on various metallurgical problems in oil refineries have recently appeared, and are abstracted together in a "composite digest" in this issue (page MA 617 L 5). Alloy steels, stainless, stainless-clad and several non-ferrous alloys are appraised for a variety of jobs, much of the information coming from refinery operators rather than alloy manufacturers.—F. P. P.

Centrifugal Casting of Non-Ferrous Metals

By lining the cast iron mold of a centrifugal casting machine with copper sheets, 1 to 3 mm. thick, the Germans (page MA 580 R 10) have found it possible to successfully cast all the non-ferrous alloys now used, such as bronze, red brass, Monel metal, etc., free from the porosity obtained when the metal came in contact with an iron or steel mold.—E. F. C.

Metal Spray Performance

The successful experience of a large oil refinery in reducing corrosion and erosion by applying sprayed metal coatings is reported by Jones and Dewey (page MA 607 R 2). Lots of good practical information on technique and conditions is included.—F. P. P.



Age-Hardening of Al Alloys

A "composite abstract" (page MA 594 R 4) on the age-hardening of aluminum alloys gives valuable data on many phases of this interesting subject. Articles from all over the world recently have discussed many interrelated factors. This type of abstract presents some of the principal points as discussed by several authorities.—E. F. C.

New Hardness Tester

A new pyramidal-diamond indenter said to be suitable for testing the hardness of thinner or more brittle materials than can be tested with conventional indenters is described by Knoop, Peters and Emerson (page MA 614 L 9).—F. P. P.

How to SAVE THE MOST MONEY with INSULATION

Make sure all your equipment is insulated with the *correct materials* in the *one correct thickness* that combines maximum operation efficiency with minimum heat waste

WHETHER or not your insulation is a paying investment depends entirely on the materials used and the amount applied. *Too much* will never pay an adequate return . . . *too little* results in heat losses that build up excessive fuel bills. But proper insulation, properly applied, will avoid both these costly mistakes. And a J-M Engineer will be glad to work out the most economical application.

Let him go through your plant and make a thorough study of your requirements. He'll give you the benefits of all the knowledge and data that Johns-Manville has accumulated during 81 years of research and practical experience on insulation problems. He can show you—from the complete line of J-M Insulations in brick, block and pipe-covering form—what materials are best suited for all your equipment. He can tell exactly how much insulation you can profitably use, and his recommendations will point the way to worth-while reductions in your fuel costs.

J-M Insulation Engineers have saved many individual plants thousands of dollars a year. There's a good chance they can do the same for you. For full details on J-M's free Engineering Service and on J-M Insulating Materials, simply write Johns-Manville, 22 East 40th Street, New York City.

JOHNS-MANVILLE JM PRODUCTS

INDUSTRIAL INSULATIONS

For every temperature . . .
For every service condition

Reduce Your Fuel Costs in 1939

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Reducing Mn Loss

Bardenheuer and Henke (page MA 648 R 1) apply the principle familiar to non-ferrous metallurgists as the Durville pouring method, in which turbulence is avoided, to the tapping of the open hearth, by tilting the ladle so as to keep the stream short. The avoidance of excessive contact with air is alleged to reduce the Mn loss greatly.—H. W. G.

Hundredths and Thousandths

Recapitulations by Guillemot (page MA 648 R 9) on Alloys and by Thews (page MA 650 R 8) on Zn base die casting alloys, while not presenting any new dope, do emphasize the fact that a few hundredths of a percent of an alloying element may exert a profound effect, sometimes good, sometimes bad.—H. W. G.

A Half Dozen Hardenability Abstracts in One

"Time Quenching," "A Test Method for the Evaluation of Aqueous Quenching Media for Steel Hardening," "Hardness Characteristics of Some Medium Carbon S.A.E. Steels," "Hardenability Variations in Alloy Steel—Some Investigations of the End-Quench Test," "Hardenability Studies on Tool Steel," and "A Hardenability Test for Shallow-Hardening Steels," abstracted in this issue (page MA 655 L 8) present a sizable symposium on this timely subject.—O. E. H.

Temperatures Determined Chemically

Obtaining surface temperatures of moderately heated materials is a difficult task but the Germans are reported to have made this easier by the development of metallic salts which change color at a specific temperature (page MA 655 L 5). Mixed with a binder, the salts are sprayed or brushed on the material.—E. F. C.

Colored Oxide Coatings on Aluminum

Coloring agents for anodic oxide coatings on aluminum are usually organic in nature. However, a new process described by Herrmann (page MA 670 L 4) is based on the use of salts of titanium, zirconium or thorium, dissolved in the electrolyte and subsequently anchored in the coating as opaque hydroxy-like compounds—F. P. P.

Spheroidizing

Hodapp and Leeder (page MA 658 R 8) report a great saving in time of a spheroidizing anneal by applying a sort of austempering procedure.—H. W. G.

Fish Eyes

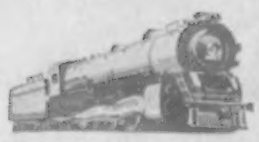
Hiemke (page MA 663 L 8) thinks that stress relieving eliminates fish eyes in welds. The nomenclature doesn't seem any too good, for the bass we caught last summer took lots of time before their stresses were relieved, while the wall-eyes were more readily subdued. Size of fish eyes and the difficulty of relieving internal stress don't always go hand in hand.—H. W. G.

High-Speed of 1100 Brinell Hardness

It is not new to heat hardened and tempered high-speed steels in molten cyanide baths, but there is much new information about this process in the paper by Morrison and Gill (page MA 656 R 5)—O. E. H.

Magnesium Alloy Die Castings

A bird's-eye-view of the widening field for magnesium alloy die castings, plus a summary of American manufacturing technique and a discussion of German automotive applications, are found in a "composite digest" (page MA 676 R 2).—F. P. P.



We Are Advertised by Our Loving Friends

Williams (page MA 655 R 7) comments on the new complex Al-V-Ti deoxidizer—or rather reagent for grain size control, "Grainal" although its producers have refrained from describing it in public as yet. If one really tried to keep a new thing truly secret, how the grapevine telegraph would hum!—H. W. G.

Progress IS PERPETUAL MOTION

Motion, fast or slow, is the breeder of problems. Whether it be the 4 feet per minute motion of a parts conveyor or the 4 mile per minute motion of an airliner—each creates problems of wear, strength, safety factors, dependability. Day by day solution of these problems is progress.

Today ***Meehanite*** castings are solving just such problems all along the line—in miniature speed reducers, in big steam turbines, in locomotives, in airplanes. Metallurgical development and progress produced ***Meehanite***; performance in service has established it.

Adaptability of Meehanite to small castings is emphasized by the speed reducer unit illustrated. Note dimensions and Meehanite parts.

Do you want to know what metallurgical engineers are doing, the world over? Look in the Current Metallurgical Abstracts. Here are some of the points covered by authors whose articles are abstracted in this issue.

Age Hardening

At least 10 papers from a recent symposium on age-hardening are abstracted (page MA 704 L 6) giving the latest information on this important subject. It is a "composite digest" and is an excellent example of the new policy of presenting in this department a comprehensive abstract of the views of various authorities on a leading topic—promptly and concisely.—E. F. C.

Furnace Brazing

Using principles analogous to those of the copper brazing process for steel, Hoglund (page MA 717R3) and Wyman (page MA 717R9) respectively describe the furnace brazing of Al and of Cu.—H.W.G.

Hard Heads in the Right Places

Production of a hard "button" in the face of a hammer, surrounded by and backed by tough material, is secured by Minarik (page MA 712R2) through local direct resistance electrical heating.—H.W.G.

Bright Nickel Plating

Hothersall and Gardam (page MA 722 L 7) examine the structure and properties of bright nickel, deposited by 3 well-known methods. Now, if some one would only do a survey on the individual merits of the 3 methods from the production and application standpoints, indicating bases for selection of one or the other by the designer or plater!—F. P. P.

Submarine Flames

Lee (page MA 723L3) points out that, instead of heating a pickling bath by injecting steam into it and thus diluting it, heating can be carried out by making a flame burn beneath the surface of the bath.—H.W.G.

Deep-Drawing Dies

Among a variety of other materials whose virtues and limitations are universally recognized, Jevons (page MA 701R5) mentions, approvingly, graphitic steel.—H.W.G.

Engineering Design with "18 and 8"

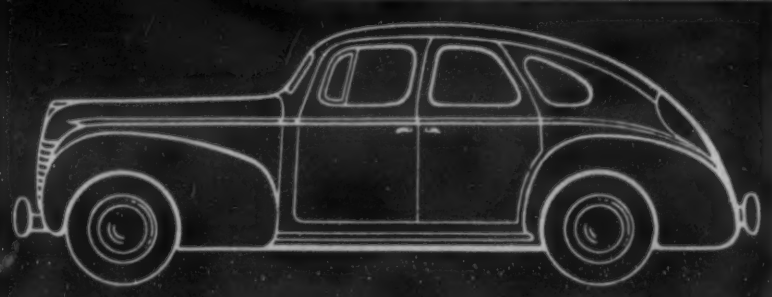
The designer depending on either the stress/strain or the stress/permanent-set relationship of "18 and 8" alone obtains only an incomplete picture of its tensile elastic properties, says McAdam (page MA 723 R 1). He recommends consideration of *both* relationships, and shows why and how.—F. P. P.

Drawing Aside the Curtain

Hazelett (page MA 701L8) now dispels much of the secrecy that enveloped the direct rolling process, and discusses the bugs that beset early attempts, and the devices adopted to lick some of them.—H.W.G.

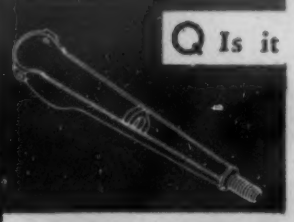
Magnesium Alloys in Europe's Motor Vehicles

A comprehensive review by Altwicker (page MA 729 L 2) of the various forms of magnesium alloys used in European cars and trucks, and their specific applications, emphasizes the trend toward greater use of magnesium in automotive construction.—F. P. P.



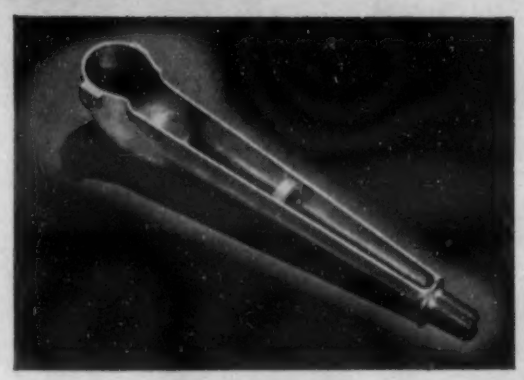
German Sponge Iron

In order to make use of some of the low-grade ores in Germany, a process is described (page MA 698 L 5) by a German author for making sponge iron from an ore containing large amounts of S, P, and SiO_2. The conventional rotating kiln is used with an Fe recovery of 90 to 96 per cent and a carbon content of 0.5 to 1.5 per cent.—E. F. C.

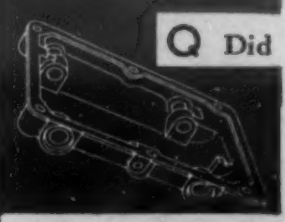


We're from Missouri

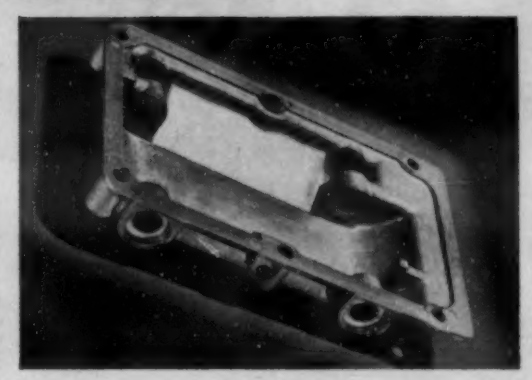
The claim is made (page MA 732R7) that a silicate treatment of Mg alloys for corrosion protection improves the mechanical properties of the alloys. That's too hard to swallow.—H.W.G.



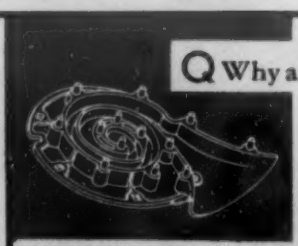
WHY DOES DETROIT PREFER DIE CASTINGS?



—A Quiz



Q Is it possible to solve both appearance and mechanical problems with die castings?



A The all-important requirement of this 1940 gear shift lever is strength. As a one-piece ZINC Alloy Die Casting this quality is easily achieved — and smooth appearance couples with low cost to make die casting the ideal method of production.

Q Did ZINC Alloy Die Castings have any influence on the design of the latest type transmission case?

A It is highly improbable that the design of this transmission cover could have been carried out by any means other than die casting. With the usual production method, machining costs would be exorbitant.

Q Why are horns back as die castings in '40?

A This is a question of arithmetic. With quality being more or less equal, the choice of material for horn construction narrows down to price. The illustrated horn part for '40 cars has a ZINC Alloy Die Cast body.

Q Why is this seal ring on new sealed beam headlights a ZINC Alloy Die Casting?

A Note the 3 integrally cast locating lugs and the knife edge on this die cast ring. The lugs facilitate assembly and the edge is spun to effect sealing. By no other method could this part have been economically produced—in one piece.

The 1940 automotive die castings reveal a flexibility of design that places this method of metal parts production in a class by itself. And this is only one industry in which ZINC Alloy Die Castings are enjoying wide application. Whether your company produces automobiles or home appliances or dime banks, you should be well versed in this modern metal and method of fabrication. Consult any commercial die caster—or write to The New Jersey Zinc Company, 160 Front Street, New York City.

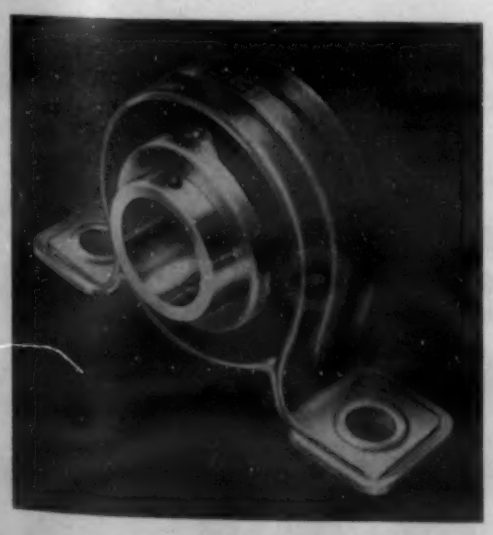
New Equipment and Materials

The SKF Rubber Flex Pillow Block



In answer to the widespread demand for a compact, sound-insulated pillow block, S K F Industries, Inc., Front St. and Erie Ave., Philadelphia, is introducing the new "Rubber-Flex Pillow Block," the result of more than 2 years' research.

This new unit comprises a self-locking bearing of the well-known S K F "Grip-lock" type. This bearing is inherently aligning, thus compensating for inaccuracies of set-up and conditions of shaft misalignment without binding or in any way impairing the load-carrying capacity of the bearing. In addition, the use of this unit brings about manufacturing economies because it requires no machining of the shaft.

The bearing is encased in a pressed steel housing equipped with felt seals to exclude dirt. The housing is provided with means for lubricating the bearing. The bearing and housing are surrounded with an elastic material having special sound-absorbing characteristics, and the material has been specially treated to make it impervious to oil and grease.

Free from the objectionable vibration usually associated with rubber mountings, this unit carries substantial loads under practically all operating conditions. Its unit construction facilitates mounting.

In short, the S K F Rubber-Flex Pillow Block constitutes a rugged, inexpensive unit which has wide application in those fields requiring anti-friction bearings with unusually quiet operating characteristics. These units are first being released in the ¾ and 1 in. shaft sizes, and are obtainable through more than 800 S K F representatives located in all parts of the United States.

Manufacturers are invited to send to the Editor items which are suitable for this Department. Illustrations are acceptable, preferably in the form of cuts no more than 2 in. wide.

Copper Oxide Rectifier For Electrotyping

A new type of electrical equipment has been installed by the Shane-Beever Co., electrotypers of Baltimore, Md., consisting of a copper oxide rectifier to supply the current used in the deposition of copper and nickel electrotypes. This is the first large installation in the United States in this industry. The plant has been in use for several months and its performance, from the start, has been highly satisfactory, especially on the score of economy of operation.

The use of the rectifier, made by the Hanson-Van Winkle-Munning Co., Matawan, N. J., involved a change from the use of motor-generator sets and also a change from the use of direct current to alternating current for the power supply. One copper oxide rectifier of 3,000 amp., 6 volt capacity replaced two 1,500 ampere motor-generator sets with DC motors. The new combination has resulted in appreciable savings in power bills. The installation cost was about one-half the cost of installing a motor generator set. The maintenance cost is very low, mainly because the rectifier has no moving parts and requires practically no attendance. The Shane-Beever company has found this equipment ideal for an electrotyping shop which normally has no electricians on its staff.

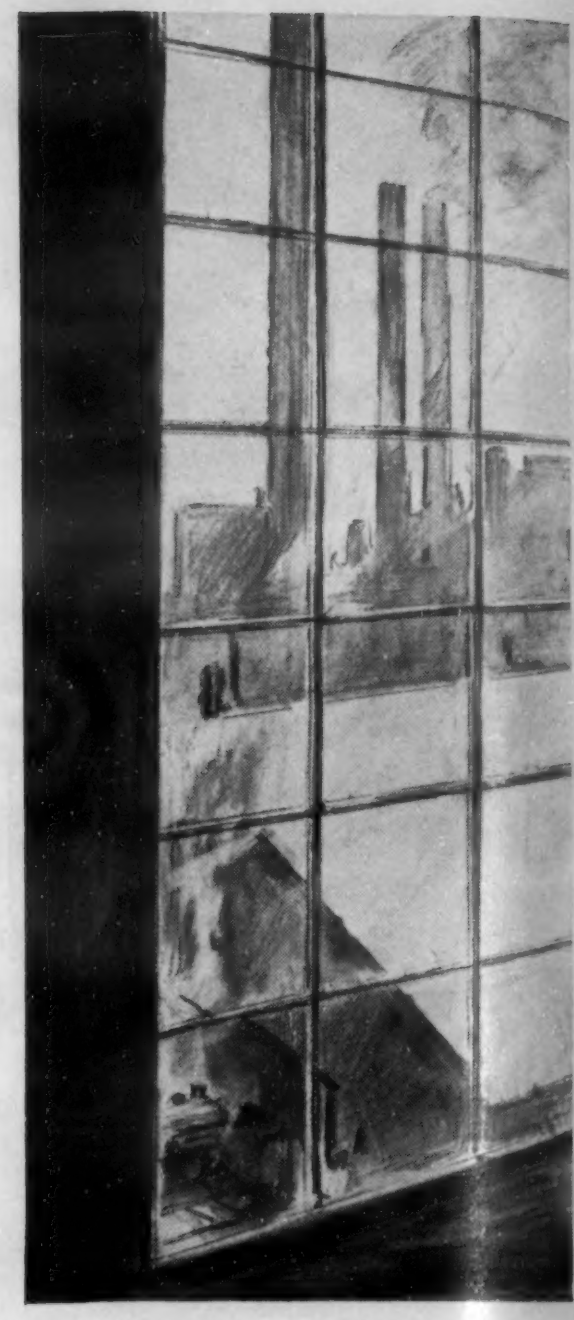
The copper oxide rectifier accomplishes the rectification or conversion of alternating current into direct current by leading alternating current to a suitable step-down transformer which changes it to low voltage, high amperage alternating current. This low voltage alternating current is led to the rectifier plate assemblies, a series of copper plates which have been oxidized by a special heat treating process so that they have a uniform, dense and highly adherent coating of copper oxide. It is at the contact surface of the copper and copper oxide that rectification takes place. The direct current is led out of the rectifier by requisite leads to the equipment using it; in the instance described above, electrolytic solutions of copper and nickel for producing electrotypes.

Eveready Lifters

Illustrated in use is one of 5 models of "Eveready Lifters" which are being placed on the market by The Bastian-Blessing Co., 242 E. Ontario St., Chicago. These units provide the answer for manufacturers who are seeking a faster and safer method of handling sheet metals, sheet glass, in fact any product that has a smooth, non-porous surface. These lifters are of patented design, incorporating giant rubber vacuum cups which are provided with automatic releases that work with the flick of a finger.

All parts are sturdily constructed, fully tested and guaranteed. The vacuum cups, which can be replaced in less than 5 min. without the use of special tools, are the only parts which are subjected to wear and the manufacturer states that this replacement cost is nominal. These lifters are available in 5 models, 2 for light work, 2 for medium work and 1 for heavy lifting.

Spectrograph



The Harry W. Dietert Co. of Detroit, announces an improvement in the applied research laboratories spectrograph. The spectograph is now furnished with an attractive and durable cover and also with an optical bench. The cover allows the spectograph to be operated in a lighted room. A film transfer case is used to remove the exposed film from the camera. This film is then taken to a dark room and developed.

The optical bench is of rigid construction, fitted with V groove to insure exact alignment of the rotating sector, lens holder, arc or spark stand, and sector photometer.

With these improvements the spectographic analysis of materials, either by the emission or absorption method, is greatly facilitated. It also allows for quick and easy film calibration with step sector.

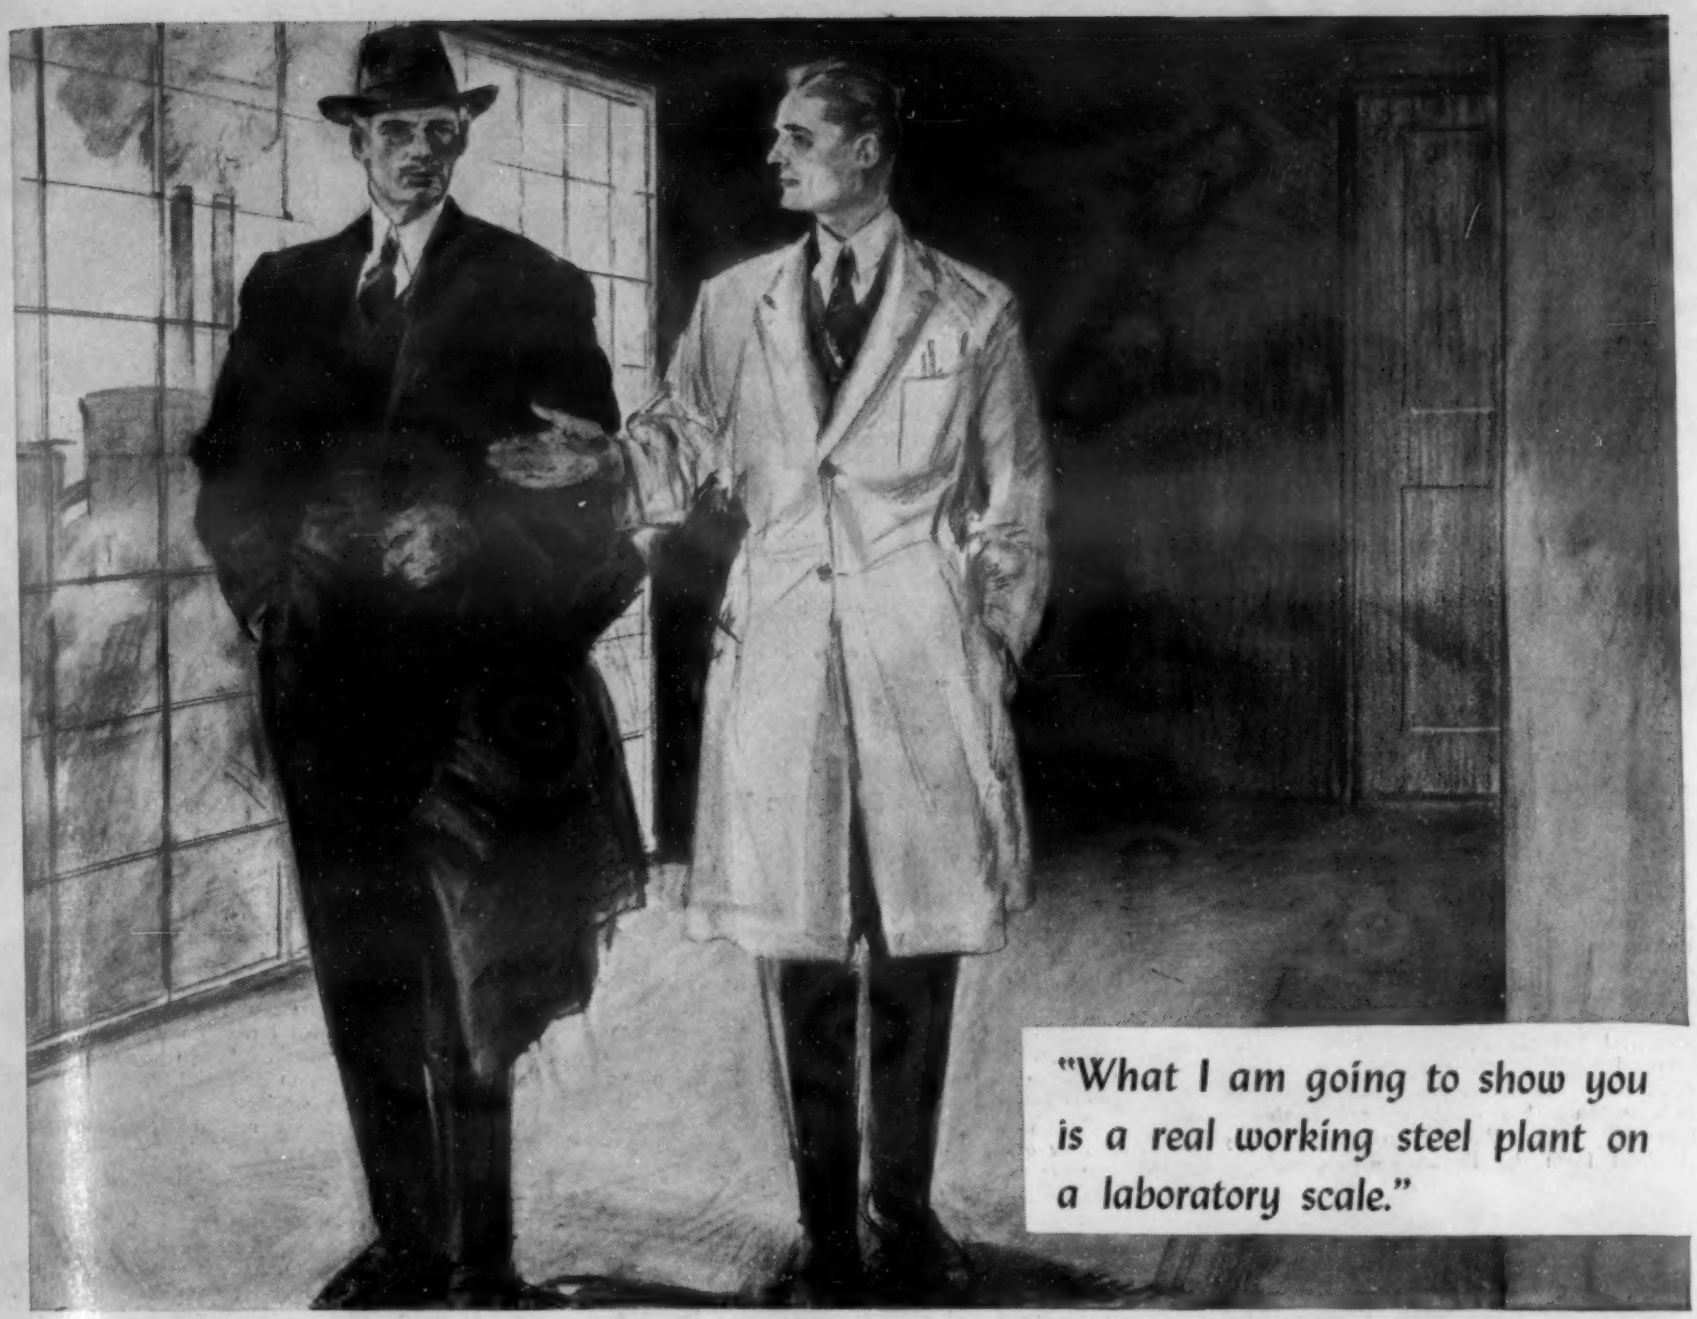
PILOTS for SHIPS
NOW A PILOT FOR STEEL



JONES & LAUGHLIN GIVES ITS STEEL MAKERS A PILOT PLANT—THE FIRST AND ONLY ONE OF ITS KIND—IN WHICH TO CHART THE COURSE OF **CONTROLLED QUALITY** IN STEEL.

"Some headline writers christened it a 'pint-sized plant'—a 'baby mill'. But what I am going to show you is a real working steel plant on a laboratory scale—with a small open-hearth furnace, small ladles and ingot moulds, a little rolling mill—everything complete for steel making, all under laboratory control. Here we carry on scientific research and development to improve the quality of J&L steel, by directing the control of its manufacture.

"As a user of steel, you benefit by our accomplishments here. We've been making quality steels for a good many years. We feel we know as much about the art of making steel as anybody. But quality steel making today calls for something more than the judgment and experience of the melter and the roller. It's a matter of scientific knowledge, measurement, control. With this Pilot Plant the skill of our workmen is now supplemented by the science of the laboratory to develop new steels for you—and better ones.

From a drawing by ORISON MacPHERSON

"This laboratory adjoins our Works, making possible quick application of its findings to actual plant operations.

"It's a pilot of progress, all right, holding a steady course toward improved steel quality —controlled quality—a course J & L has pursued for many years.

"But we'd better be getting on, for it's time to tap a heat from the Pilot Plant open-hearth furnace. 'Pint size' it may be, but it's full scale in value."

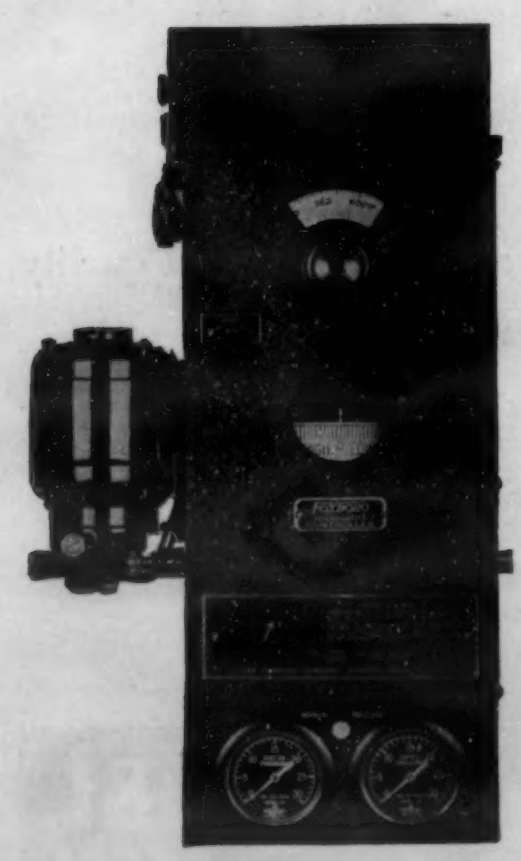
J & L — PARTNER IN PROGRESS TO AMERICAN INDUSTRY



Potentiometer Control Pyrometer With Air Operated Valves

A new potentiometer control pyrometer, combining the accuracy, responsiveness and wide temperature range of electrical temperature measuring methods with the simplicity, economy and dependability of controlled valves operated by air diaphragm motors, has been announced by The Foxboro Co., Foxboro, Mass. Designed to actuate air-operated valves which are unaffected by dampness, oily vapors and corrosive atmospheres and are free from arcing and sparking electric contacts, these controllers are particularly applicable to gas, oil, steam, hot water and hot air heating, or brine, cold water or air cooling systems.

In method of measurement, electrical circuit, mechanism for detecting temperature change, construction and general appearance, these control pyrometers are identical with other models of Foxboro potentiometer controllers. In this instrument, by means of a fixed setting of the temperature dial and slide wire contact position, the mechanism for detecting temperature change acts directly in detecting galvanometer deflection, thus transmitting in control action the full sensitivity of the measuring system. The "knife edge" detecting device can pick up galvanometer deflection of 0.002-in. representing sometimes as little as 1/3 of 1 deg. F.

Direct setting of the 12-in. scale is possible to 1/5 of 1 per cent of scale range. Available ranges are from minus 300 deg. F up to 2,800 deg. F. These instruments are equipped with an automatic safety shut-off, so that if the thermocouple circuit is opened, through burnout or damage, the instrument automatically puts the valve in "safe" position.

The air control system consists of a positive, open-and-shut air control mechanism. Recommended air pressure is 17 lbs. per sq. in. To meet the majority of requirements, valves are provided in both single-seated and double-seated balanced types. Further information may be obtained from the Foxboro company.

Electric Etcher for Steel

A new, low-priced electric etcher marks iron and steel and their alloys, including hardened steels, legibly, permanently, easily and economically. It is another development of the Ideal Commutator Dresser Co., 1928 Park Ave., Sycamore, Ill. This etcher is used in the same manner as a pencil and engraves names, sizes, models, numbers or other important data on smooth surfaced parts, tools, dies, saws, plates, gears, etc. Prevents mistakes in assembly, avoids confusion in selection of tools and materials, lessens theft and loss.

The complete unit includes a handpiece and alloy point, transformer with three taps, special primary cord with tap-changing switch, secondary leads of No. 8 wire and a work plate. Weight is 12 lbs. Three etching speeds are controlled by a switch on the primary cord. Depth of the etching is governed by the speed at which the point is moved over the metal.

It is easy to use. Just plug into a suitable wall socket. Standard unit is for 110 volt, 60 cycle service. Also available for other alternating current circuits.

A 150-Ampere D-C Arc Welder

A new 150-am., direct-current, single-operator arc-welding equipment has been announced by the General Electric Co., Schenectady, N. Y., which further extends its line into the field of light-gage work. The new equipment, because of its high instantaneous recovery of voltage, provents arc pop-outs at all points in its wide welding range with any good bare, lightly coated, or heavily coated electrode. Its stability prevents excessive current surges, thus avoiding excessive spatter loss and sticking of the electrode.

Any welding current within its entire range can be quickly obtained by means of a 3-point selector switch and an easily operated dial for intermediate adjustment. Additional assurance of dependable operation is provided by a reliable means of self-excitation. Isothermic overload protection permits the equipment to carry maximum safe overloads without danger of burnouts and without unnecessary interruptions on harmless overloads.

The new d-c equipment is rated 150 amp. at 25 volts and its range of adjustments varies from 20 to 200 amp. at 25 volts.

An All-Purpose Label Adhesive

To meet the long-standing need for an adhesive capable of adhering to practically any surface, Paisley Products, Inc., 1770 Canalport Ave., Chicago, and 630 W. 51st St., New York, announces that, following exhaustive tests, its new product, "Grip-Tite Label Paste" is now being placed on the market. In an interview Earl C. Lenz of Paisley Products, Inc., said:

"This new adhesive has been perfected to make available to label users a paste which can be relied upon to hold dependably to practically any surface under almost any condition of temperature, atmosphere or climate. Countless tests have been carried on which have demonstrated the excellent adhesive power of our new Grip-Tite Label Paste on plain, lacquered and lithographed surfaces of tin, iron, copper, brass, lead, aluminum, stainless steel, bakelite, hard rubber, tile, leather, wood (either painted, unpainted or varnished), paper board, porcelain, glassware, galvanized ware, plastics and similar surfaces."

The new product is available in 1, 5, 30 and 50 gal. sizes, f.o.b. Chicago or New York City and a low price schedule makes this new paste of interest to both large and small users.

"Compar" Indicating Micrometer and Comparator

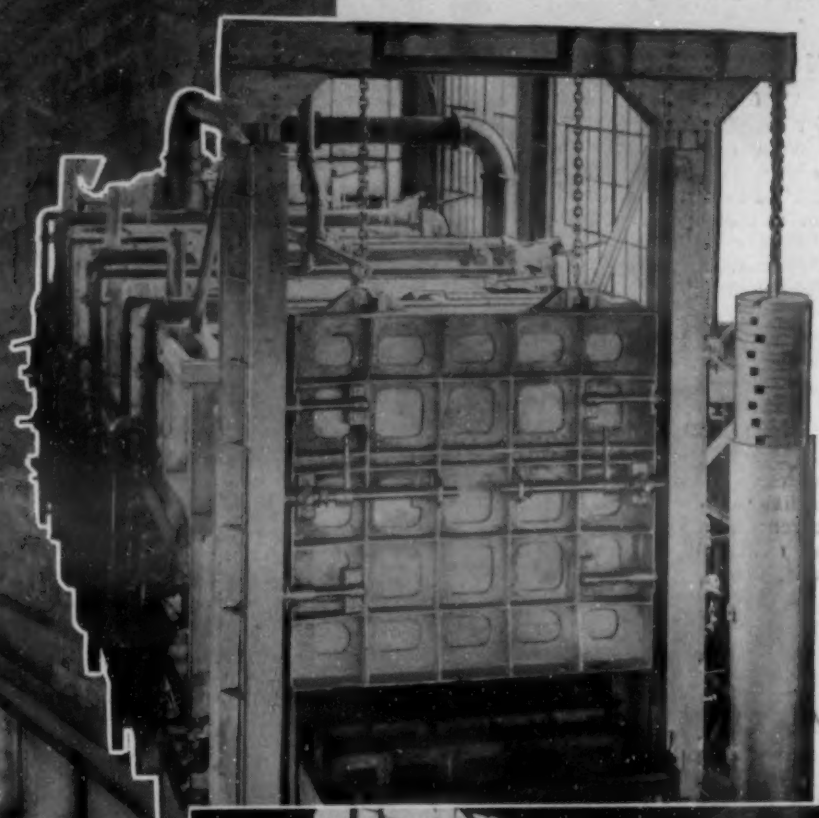
The George Scherr Co., Inc., New York, has introduced a new "Indicating Micrometer and Comparator" which includes several interesting and important improvements. Among these are the elimination of all gears and racks from the indicator mechanism. Instead, the knife-edge lever type is used, which is claimed to make the instrument more accurate, more durable and less subject to loss of precision through constant use. It eliminates the uncertainty of measuring feel since it includes a feature which makes the measuring pressure visible. There is an anvil relieving button which moves back the lower anvil for inserting and removing work. When the work is inserted and the button released, the anvil is pressed against the work by a light pressure return spring. Thus the reading is sure to be the same.

The "Compar" Indicating Micrometer and Comparator is constructed to withstand the constant wear and tear to which an instrument of this nature would be subjected in the machine shop and in quantity production. All delicate mechanism has been eliminated, resulting in a compact, sturdy instrument that measures in 1/10000 in. and is built for hard, all-around use.

Small Radiant Tube Annealing Furnace

A small, cylindrical, bell-type annealing furnace, heated with vertical radiant tubes, and intended primarily for heat treating small tonnages per charge of coiled strip steel and coiled rod and wire, has been developed and introduced by the Lee Wilson Engineering Co., 1370 Blount St., Cleveland.

This type of furnace is used for bright annealing and spheroidizing of hot and cold reduced material for both steel and wire and also for low and high carbon steels. Copper and brass as wire or strip can also be suitably annealed in it, it is said. Liquid seal is provided for as well as the introduction of protecting gases. The furnace is claimed to have the inherent characteristics of an electric furnace plus the advantages of throttling heat control and low cost of heating per pound of material handled. There is a fan in the base for promoting circulation of gases.



The furnace is pointed to as applicable particularly where there are small charges of varying time temperature cycles. It can be used in shops where time in process must be reduced to a minimum and small orders can be run through quickly.

LEFT: *Interior of large car-bottom furnace installed at the Wycoff Steel Company, Chicago. 10,000 straights of Armstrong's Insulating Fire Brick assure maximum operating efficiency.*

BELOW: *Exterior view of same furnace.*

SURFACE COMBUSTION

builds high insulating efficiency into these modern furnaces

with ARMSTRONG'S BRICK

SURFACE Combustion Corporation of Toledo, Ohio, is one of many leading furnace manufacturers who build maximum insulating efficiency into their equipment with Armstrong's Insulating Fire Brick.

These high quality brick meet all the requirements for efficient service. Their use permits thinner furnace walls which results in a larger hearth area. Their light weight makes them ideal for arch work. And their low heat capacity permits the furnace to come to temperature with far greater speed.

All these advantages of Armstrong's Brick assure lower fuel costs, more accurate temperature control, and greater flexibility of operation. Armstrong's Brick are available in five types for a wide range of temperatures and uses.

Armstrong will gladly furnish specifications outlining the standards required for the different physical characteristics with permissible tolerances. Write today for samples, prices, and descriptive literature. Armstrong Cork Company, Building Materials Division, 982 Concord St., Lancaster, Pennsylvania.

IMPORTANT FEATURES OF ARMSTRONG'S BRICK

1. Ample insulating value
2. High crushing strength
3. Accurate sizing
4. High spalling resistance
5. High salvage value
6. Complete line for wide temperature range
7. Ability to withstand handling in shipping and installing
8. Special shapes of all types and sizes
9. Easily cut on the job
10. Stocks available in principal cities
11. Laying cements with same physical characteristics as brick
12. Complete line of refractory facing cements for protective coatings

New Welding Control

Uniformly high quality welds, particularly for applications where the expense and inconvenience of X-ray do not seem justified, are now made possible with the "Arc-Length Monitor," new product developed by the research division of the A. O. Smith Corp., Milwaukee.

In the vast majority of welding applications throughout industry, there has been no routine method to insure high quality work with this universally accepted production tool. Heretofore quality was at the mercy of the human element, which rested upon the training, experience and attitude of the individual welder.

X-ray has proven satisfactory within limits, but it cannot be depended upon to reveal harmful foreign inclusions in the weld metal or excessive amounts of nitrides. Various recording methods are also in use to indicate current and voltage values after completion of the weld, but there are also "after the fact" indications.

The Arc-Length Monitor is a practical development which fits into present shop practices. It helps the worker make a good weld while he is in the act of welding. Smith research proved long ago that, while control over voltage of itself is no definite assurance of a good weld, in nearly every case of poor welds there was a relation to the voltage involved. The situation, if controlled through definite indications to the welder during the process of welding removes one of the main variables in welding technique. Thus it promotes higher quality welds.

The function of the device is as follows: The welder is informed of the length of his arc by means of two tiny bulbs, mounted inside his welding helmet, one on each side of the window through which he observes the arc. Both bulbs are normally dark at the selected voltage. The one to the right glows faintly, and with increased intensity, as the voltage increases from that selected; the one to the left responds similarly as the voltage decreases from that selected. Maximum brilliance is kept well below the point of hurting the operator's eyes or interfering with his work. The instrument itself, which contains signal lights similar to those in the welder's helmet, is placed where it can be observed by the production or welding supervisor.

The Monitor will be found particularly effective where very light gage materials are used, particularly such expensive metals as stainless steel, requiring close control of the arc. It has also proven invaluable for periodically checking the ability of experienced operators and training new operators. Experiments in Smith's huge welding plant show that new operators acquire ability to hold a steady arc in about one-third the usual time. The Monitor is also useful in minimizing controversy over test results in laboratories where it is desired to duplicate working conditions for welded specimens. Incidentally, it has the psychological effect of giving the welder an inducement to exercise extra care in his work.

A Si-Al Alloy for Piston Rings

In the field of piston rings, cast iron has long held a dominating position. Ease of founding, good machinability and low metal cost have made it an economical material for the purpose. Good bearing qualities, particularly under the conditions of poor lubrication which often obtain, and the ability to retain its physical properties at quite elevated temperatures, have both been instrumental in maintaining its almost exclusive position for so many years.

Ray Day Pistons, Inc., Seattle, Wash., as pioneers in the successful manufacture of aluminum alloy pistons, felt many years ago that an outstanding improvement in piston ring performace could come in the same manner (and to a greater extent) that piston performance was improved—by the substitution of a suitable aluminum alloy for cast iron. Seven years ago it was established through exhaustive tests that none of the then existing alloys was applicable. While it was demonstrated that marked advantages in engine operation were to be derived from the light weight and high thermal conductivity of those alloys, their low elastic modulus and rather poor bearing properties made it imperative that an alloy be developed to exactly suit the needs. Such an alloy (U. S. Patent No. 2,131,076) now has been in production for about 2 yrs. Essentially, it is a hyper-eutectic silicon-aluminum alloy containing suitable age hardening constituents and very closely controlled as to impurities. Graphitic silicon is present in about the same proportion by volume as graphitic carbon in high quality grey iron, and contributes, of course, to the excellent anti-frictional qualities of the alloy.

Elastic modulus of the alloy, as heat treated for use in rings, is 15,000,000 lbs. per sq. in., determined from finished rings or from transverse tests. It is this remarkable improvement in elastic modulus over the conventional 9,000,000 to 10,500,000 lbs. for other alloys that makes it use in rings feasible. For while it is only three-fourths to two-thirds the modulus for good ring iron, the force of inertia due to mass (and which, in high speed engines is the cause of ring "paralysis") is only one-third, so that its advantage in this respect is obvious.

Thermal expansivity of the alloy is 16.1 x 10-V per deg. C., the lowest of any useful aluminum alloy produced commercially to the knowledge of the writer. Pistons have been produced of the simplest and strongest trunk type to take advantage of this low expansivity, and over a period of years, in the most gruelling types of service, these pistons have proven unquestionably superior to those cast from other alloys.

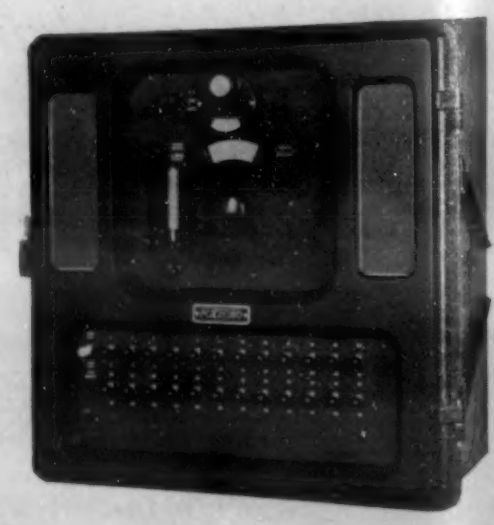
The alloy is used in two conditions—heat treated to 180 Brinell for piston ring use and to 110 Brinell for piston use. Ductility under either condition of heat treatment is not measurable.

In short, the aim has been to provide an alloy having those properties of cast iron that are considered valuable without sacrificing the thermal conductivity and low density of aluminum. Thousands of hours of successful operation in the field indicate that the company achieved such a combination of properties.

Strip Heaters

Two new types of strip heaters designed to produce fast, economical heat have been announced by the Westinghouse Electric & Mfg. Co. Made in two temperature ratings, 750° F. and 1200° F. on the sheath, these heaters are particularly applicable on crane cabs, valve house, elevators, ovens, metal water tanks, pipe lines, hydrants, hot tables, metal moulds, foundry platens—wherever ease of application and convenience are requirements.

Heaters may be obtained either with both terminals at one end or at opposite ends for installation convenience. Heating elements, with refractory insulation and sealed against moisture, are completely enclosed and bolt holes are provided at each end for quick and permanent installation.



Available for operation on 115 volts, 230 volts and two styles for 250 volts, the heaters include sizes of 8, 12, 18, 24, 30½, 36 and 43 in. in length with ratings from 150 to 1250 watts.

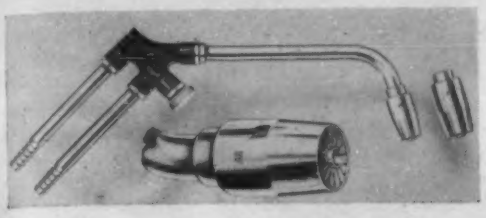
Indicating Potentiometer

A new key-switch cabinet indicating potentiometer has been introduced by The Foxboro Co., Foxboro, Mass., to provide centralized temperature indication for numerous and scattered points in industrial plants. As many as 82 switches may be obtained on the key-switch panel, assuring complete coverage of all desired points for temperature information.

Switch identification plans are arranged for maximum convenience beside the indicating panel containing the scale and vernier dial-knob. Designed for ease of installation, the instrument case is of the universal type, suitable for surface mounting on the wall or flush mounting through the instrument board. All connections are made from the front of the board, greatly simplifying the wiring. The case, made of pressed steel, is provided with 10 knockout openings so that connections can be made at the top, bottom or sides.

In order to make balancing rapid, yet precise, the potentiometer is equipped with a vernier dial-knob. A unique vernier-type rheostat makes standardizing easy and exact. The instrument can be used with either single or double range (upper and lower) for one or two types of thermocouples, and with scales calibrated in degrees Fahrenheit, degrees Centigrade or in millivolts. High scale legibility is obtained by use of a scale 17-ins. in length. Temperature readings can be made down to 1 degree on a 1,000 deg. F. scale. Accuracy of the indicator is guaranteed to be within 1/4 of 1 per cent of the full scale.

For accurate standardization, the potentiometer circuit is so designed that when the galvanometer is used to balance the circuit against the standard cell, the galvanometer deflection is four times as great as its deflection on temperature measurement.



The automatic cold junction compensation coil is interchangeable with a coil of constant resistance value, which can be substituted when the instrument is checked electrically. In checking, then, this feature eliminates the need for calculation or allowances for the compensation factor. Mounted on the connection terminal strips, the automatic cold junction compensation coil, for all ranges, has the same temperature as the ends of the thermocouple extensions, thus providing accurate compensation. All switches, and the rheostat, are totally enclosed and dust-tight.

(Continued on Page MA7)

Blowpipe With Radial Grip Tip

The S. S. White No. 8 Blowpipe, manufactured by the S. S. White Dental Mfg. Co., 10 E. 40th St., New York, is a high intensity gas and air torch for general purpose soldering, brazing, etc. It is an extremely well made torch and has a number of novel features which give it a high efficiency and make it easy and comfortable to use.

It is regularly supplied with three carburetors: No. 1 for coal gas (also called manufactured or city gas); No. 2 for natural gas, propane, pyrofax, or other petroleum gases; No. 3 for mixtures of these gases. Carburetors can

be changed in a few seconds with a screw driver. Each carburetor is so constructed that any increase of the flow of air at the bench connection automatically increases the flow of gas from the main line.

Two readily interchangeable tips are available. The smaller, supplied as standard equipment, is suitable for all ordinary soldering and brazing operations. Its flame can be held to a fine needle point or increased to a strong blast. The larger tip is for use where large quantities of alloys must be rapidly melted. The unique design of the tips causes two concentric flames to be produced: A strong, cone-like inner flame, and a distinct outer flame that acts as a pilot light. No matter which gas or gases listed herein is used, and no matter what type of flame is required, the flame produced will be clear and definite.

The "pistol" grip handle enables the operator to use the blowpipe with hand and wrist in a comfortable unstrained position. By simply loosening a nut, the pipe and tip can be turned to produce a flame in any direction for heating or soldering operations where it is desirable to have the blowpipe rest on the bench, thus leaving operator's both hands free.

Automatic Welding Head

An unusual application of fractional horsepower motor drive has been recently made by Una Welding, Inc., in collaboration with the engineers of The Ohio Electric Mfg. Co., 5900 Maurice Ave., Cleveland, to obtain exceptionally accurate and sensitive electrode-feed control on the former company's automatic metallic arc welding machines. This control system consists of two motors instead of only one, as in other types. The larger of these motors, a separately-excited direct current machine, tends to feed the electrode rod down against the work; and the other, a constant-speed a.c. motor, to pull it upwards away from it. The two units are geared together by a differential on the feed mechanism shaft so that the electrode rod is moved up or down according to the difference between the two motor speeds. The "down" motor is connected between the electrode and the work, the "up" motor being controlled by a relay in series with the welding current circuit. By the use of a rectifier, the system may be used when the welding current is alternating instead of direct. On pressing the "start" button, the "down" motor receives full open circuit welding voltage, (cut down by means of tapped resistance to 20 to 40 volts), and it therefore feeds the rods downwards till it touches the work. The "down" motor is now practically short-circuited, and is de-energized—excessive current flow being prevented by the series rheostat used for pre-setting the arc length. The rush of welding current, however, operates the relay energizing the "up" motor. This instantly pulls the electrode rod away from the work, thus striking the arc. Both motors continue to run; the rate of feed being controlled, as before, by the difference in the motor speeds—which in turn is directly proportional to the voltage of the arc and the rate at which the rod is consumed, thus taking care automatically of any irregularities in welding conditions which may occur as the work progresses. The motors themselves are designed for low starting current, prompt response to changes in welding conditions, and to conform to close speed limits for any given voltage, whether they are starting up cold or are heated by the day's run.

"Airkool" Air-Hardening Die Steel

The Crucible Steel Co. of America, 405 Lexington Ave., New York, has introduced a new die steel to which has been given the name "Airkool." It is said to have been developed in response to requests from many industries for a new steel intermediate between the high carbon high chromium and oil hardening types in performance, at the same time approaching the non-deforming and easier machining properties of the latter.

As a result of extended research, the company developed a composition which "exactly fitted the demand." Because of the simplicity of its hardening treatment it was christened Airkool. It is believed to be of outstanding importance to die steel users, in that it combines air hardening characteristics with non-deforming properties. It is recommended for applications in which toughness is one of the principal requisites.

It is an air hardening Cr-Mo-V steel. Annealed to 1600 to 1650 deg. F. and cooled in the furnace, its Brinell is 197 to 223. Hardened in air from 1750 to 1850 deg. F. and tempered at 300 to 1000 deg. F., its hardness ranges from 63 to 58 Rockwell C.

THE LAST STEP

IN THE PRODUCTION OF

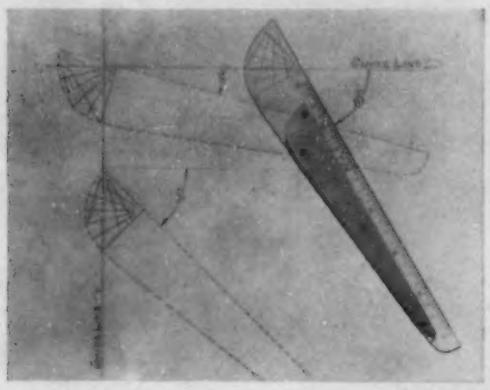
ST. JOE *Electro-Thermic* ZINC

The ore from the St. Joseph Lead Company's zinc mines at Edwards and Balmat, New York has passed through the smelter at Josephtown, Pa. The last step in production is now being taken, the casting of the slabs of zinc. Soon they will reach the consumer, and another transformation begins. Some will go to rolling mills and emerge as strip or sheet. Galvanizers use others to protect wire fences and sheet steel roofing against corrosion. Tons of them will appear in the countless products made of brass and nickel silver. Irrespective of the purpose for which it is to be used, one of three grades of St. Joe Electro-Thermic Zinc will meet your requirements.

ST. JOE HIGH GRADE • ST. JOE INTERMEDIATE • ST. JOE PRIME WESTERN.

ST. JOSEPH LEAD COMPANY

250 PARK AVE., NEW YORK ELdorado 5-3200



PLANT AND LABORATORY, JOSEPHTOWN, BEAVER COUNTY, PA.

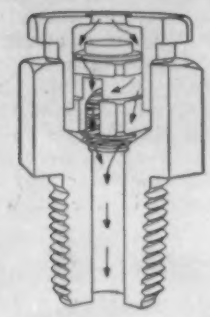
The U-Draft, a Pocket Drafter

A new pocket "Drafter" known as the "U-Draft Pocket Drafting Machine" has been put on the market by L. G. Wright, Inc., 5209-36 Euclid Ave., Cleveland. This new instrument combines T-square, triangles, and drafting scales into a unique combination so that the instrument literally is a pocket size drafting machine. It is 7½ in. long overall and 1¼ in. wide.

The instrument consists of a graduated scale and a protractor head on which lines are inscribed at 15-deg. angles to the horizontal scale. The instrument is made of pyroxlin specially treated drawing instrument material and all of the scales are engine divided on the pyroxlin. A metal stiffener, eyeleted to the pyroxlin, keeps the instrument flat.

In use it is possible to make an accurate drawing 6 by 6 in. on any kind of paper. With the instrument, angles 15 deg. apart may be drawn and all lines may be drawn accurately to length. It is supplied in 4 different graduations, as follows: full size 1/16 in, millimeters, full size 1/10 in, and also 1/8 in. and ¼ in. equals one foot.

The tool is ideally suited for all types of mechanical drawings, cabinet drawings, installing diagrams, mathematical solutions, graphical calculations, floor plans, lettering, layouts, quick sketches, and dimensioning on larger drawings. It is likewise an excellent premium item for engineering salesmen to distribute. List price (including instructions) is 50c providing a choice of graduations.



Container for Salts

The A. F. Holden Co., New Haven, Conn., offers a new 100-lb. container for "Holden Light Case" and "Holden Hard Case" that is more usable, from the customer's standpoint, inasmuch as it has a large cover that makes it easier for the operator to remove materials from the drum. Incidently because of its reduced diameter the package occupies less floor space in the heat-treating department.

The Holden company exhibited these new series of baths in operation at the National Metal Show in Detroit. The value of these products lies in their easy washing plus the fact that for the first time the carbonate in a casing bath is made of value. The company, through its research department, has developed a new reactive carbon with carbonates which acts on a percentage basis so that CO is generating not only from sodium cyanide present in the composition, but from the carbonate as well, which is a by-product of sodium cyanide oxidization.

Trends in equipment depend on the trends in the industries served. You will find the editor's interpretation of these, based on news as it happens, in "Trends" on page MA 70.

Alemite Button Head Fitting

A new, free-flow giant Alemite button head fitting, designed to speed-up the lubrication of heavy machinery, has been announced by the Stewart-Warner Corp., Chicago. Bearings requiring large amounts of lubricant—such as those on tractor track rolls—can be lubricated in less time than with older types of fittings, and with less chance of damage to grease gun equipment through overloading, the manufacturer states.

In the new fittings, the usual valve core has been replaced with one which has a flat face and seat, and which, when open, offers practically no impediment to the free flow of lubricant. By expanding the diameter of the valve retaining-spring, lubricant flows unobstructed through the center of the spring and not through its compressed coils. The improved valve opens easily under slight pressure, and provides an effective and tight seal against the loss of lubricant when the pressure is removed.

The bodies of the new fittings are hardened to withstand rough treatment. Their smooth tops, which eliminate the cutting or wearing of the coupling sealing washer, are a new feature.

Ordinarily it is impractical to bring heavy machinery to a power-driven compressor, and many operators rely on hand-operated portable compressors to lubricate their equipment. Although many of the portable compressors are capable of producing high pressures, forcing lubricant through partially-obstructed fittings requires time, labor and a strain on equipment which can be eliminated by the new fitting, Stewart-Warner engineers claim.

Test On Hardened Lathe Bed

One of the most interesting and unusual experiments ever made in the lathe field is entering its seventh consecutive month in the test laboratories of the Monarch Machine Tool Co., Sidney, Ohio. More than 7 months ago, when Monarch announced its flame hardened and ground lathe bed, a wear test was started between a hardened and unhardened lathe bed.

Two similar beds were selected for this test, one of them being unhardened, while the other was flame hardened and ground. Each carriage carried a 500-lb weight. A crank arrangement, operated by an electric motor, moved each carriage 1 ft. of travel on each lathe bed. At the time this test was announced, over 1,250,000 passes had been made over each bed.

This break-down test has been going on without interruption, except during calibration and measurement inspections, for over seven months. As of November 2, the two carriages had made more than 6,000,000 passes over each bed. The unhardened bed has worn more than 0.002 in. over the entire area. It shows a deep score on the inside of the front flat and on the carriage "V" as well. The flame hardened and ground bed has no measurable wear and not a single scratch.

Ferromagnetic Cores for High Frequency Transmitters

A new ferromagnetic core, developed primarily to enable transmitter design engineers to reduce the size and increase the efficiency of tank circuits and loading coils, and provide for continuous and smoth adjustment of circuit tuning over wide frequency ranges, is announced by P. R. Mallory & Co., Inc., Indianapolis, Ind.

The use of finely divided iron cores in radio receiver design is firmly established and of unquestioned value. Heretofore, the use of cores in transmitting has been impractical due to problems of voltage breakdown and heating of the material in the intense field. The new Mallory core combines the inventive genius of W. J. Polydoroff—a pioneer in the development of iron cores for communication use—and the science of powdered metallurgy as perfected by Mallory engineers. This core successfully overcomes previous objections to the use of ferromagnetic materials in R. F. power circuits.

General applications include (1) antenna loading inductances; (2) antenna chokes; (3) tank circuits in final amplifier stages; (4) aircraft, mobile and portable transmitters, and (5) modulation transformers and chokes. Special shapes of Mallory cores may be had to replace other types of laminated cores in audio modulation circuits. The use of these finely-divided cores results in extended frequency response and higher circuit efficiency.

The cores are available in cylindrical form with diameters varying from 1 5/16 in. to 8 3/16 in. Length can be made as desired, but for optimum and economical considerations the recommended length should be twice the diameter. All Mallory cores are made of highly compressed ferromagnetic particles of extremely small size, with a density of approximately 4.5. Insulation resistance is approximately 1000 ohm-cm. Two core materials for different frequency ranges and applications are available in all diameters, and in 2 grades, Grade A and B.

Chrome Leather Handguard

A reversible chrome leather handguard, which fits either hand, has recently been placed on the market by the Industrial Gloves Co., 702 Garfield Blvd., Danville, Ill. This new handguard, designated as No. 12237, provides efficient protection in handling operations including metal sheets, metal shapes, stampings, bars, angle irons, etc., and gives double service because it may be worn on either hand.

In order to assure maximum protection, steel ribbons have been placed diagonally on wearing surfaces to give greatest protective service against sharp, cutting edges of objects handled. The guard is 7 in. long and may be worn in connection with cotton glove or over bare hand as preferred. It may be had in 6 and 7½ in. lengths and is available in plain leather, and without steel ribbons, also, in wool felt, cotton webbing and rubber.

Determination of Adhesion Energy and the Problem of a Characteristic Value for Collectors. Contribution to Flotation (Adhäsionsenergiebestimmungen und eine Betrachtung über die Möglichkeit der Bildung einer Sammlerkennziffer. Ein Beitrag zur Schaumschwimmaufbereitung) S. VALENTINER. *Kolloid-Z.*, Vol. 83, Apr. 1938, pp. 1-9. Theoretical and experimental research. The following 2 factors must be considered in evaluating the suitability of a collector for flotation: (1) Adsorption of the collector molecules by the components of the mixture, (2) interaction between the molecules of the collector and frother. Contact angle determination or, better, adhesion energy determinations yield information on the adsorption capacity of the components. When interpreting the experimental data, the solubility conditions must be considered. Adhesion determinations were made for a number of systems. The surface tension of several solutions, their boundary tension against pure benzol and water, and the contact angles of some solutions against galena were determined. EF (1)

Collection of Coarse Gold and Mineral—Use of Strakes, Jigs, Hydraulic Traps, Unit Flotation Cell and Scavenging Cells. *Chem. Eng. Mining Rev.*, Vol. 30, Sept. 10, 1938, pp. 479-480. Practical. Jigs cannot operate to advantage on all types of ore. When the Au or mineral, or both, are comparatively coarse, they may be used. Disadvantages of the hydraulic trap are the dilution resulting from the added water and the fact that a large quantity of Fe from the grinding operation may be collected. A unit flotation cell will replace a jig. The discharge from the ball mill is fed directly to the flotation unit and a froth concentrate removed. Scavenging flotation cells are used to treat the residues from the roasting-cyanidation plant of Loloma (Fiji) Gold Mines, N. L. Tavua, Fiji. These cells are expected to reduce tailing losses and to take care of plant irregularity, such as imperfect roasting or agitation. WHB (1)

Economy in Dump Treatment. JOHN C. RUSSELL. *Eng. Mining J.*, Vol. 139, Sept. 1938, pp. 52-53. The dump of the Santiago Metals Co. on Mt. McClellan, Colorado, furnished a product of such grade that only the fines could be economically handled. The principal difficulty in milling was the tendency of the coarser material in the primary table tails to build up in the conditioner. This was overcome by installing a wet vibrating screen at this point, the separation being made at 28 mesh and the oversize being by-passed around the flotation circuit to the pilot table. The amount of material by-passed is less than 10%. Flotation reagents employed on this oxidized dump ore are sodium ethyl xanthate, copper sulphate, pine oil and Barrett's No. 2. The flowsheet is shown. WHB (1)

Effect of Sea-water on the Flotation of Sulphide Minerals. GAICHI YAMADA. *Suiyokwai-Shi*, Vol. 9, Aug. 1938, pp. 589-598. In Japanese. Original research. The floatability of pyrite, galena, chalcopyrite, black jack, ruby Zn, marmatite, enargite, arsenopyrite, stibnite and molybdenite were examined in 3.5% NaCl solutions of various H-ion concentration by using camphor white oil, K-ethyl xanthate and kerosene. The floatability of these sulphide minerals in sea-water is similar to that in distilled water. The "natural froth" of flotation in sea-water, i.e. the froth without any addition of frothing agent, generally has no collecting power, but easily floatable sulphide minerals, *e.g.* stibnite and molybdenite, are partially collected in the natural froth. Maximum floatability of galena in sea-water lies in the pH range 5.1-10.6; that in distilled water in the wider range 1-11. Floatability of enargite is notably depressed in sea-water. HN (1)

Pullman (Wash.) Unit, Electrometallurgical Section. H. A. DOERNER. *U. S. Bur. Mines Rept. of Investigations* No. 3406, July 1938, pp. 25-28. The program of this laboratory and progress thereon are described. Beneficiation of magnesite ores by 3 processes has been reported: (1) Cyclic leaching, (2) selective calcination and screening and (3) flotation. The magnesite concentrate is calcined and $MgCl_2$ formed by reaction with C and Cl. $CaCl_2$ impurity can be removed by distillation or Mg can be distilled from the Ca-Mg alloy obtained by electrolysis of the $CaCl_2$-$MgCl_2$ mixture. Experiments on direct reduction of MgO by C are reported. AHE (1)

Producing Zinc at Trail—Roasting, Leaching, Electrolysis, Melting, Cadmium Recovery. JOHN B. HUTTL (Staff) *Eng. Mining J.*, Vol. 139, Sept. 1938, pp. 42-45. Treatment of Sullivan and custom Zn concentrates involves suspension roasting, leaching, purification, electrolysis, melting and Cd recovery. The outstanding development at the Zn smelter is the perfection and adoption of the burning concentrate roasting process. The roasting of the Zn concentrates in suspension is conducted in converted Wedge roasters. Flowsheets are shown for the main leaching plant, the oxide leaching plant, and the Cd recovery plant. WHB (1)

Former Importance and Future Possibilities of the Lead and Zinc Deposits on the Left Bank of the Ruhr in the Mining Distric of Werden (Frühere Bedeutung und Zukunftsaussichten der Blei- und Zinkvorkommen auf der linken Ruhrseite im Bergrevier Werden) B. KAMPERS. *Glückauf*, Vol. 74, Aug. 27, 1938, pp. 733-738. The geological conditions are discussed, and the present and future chances that may justify reopening and reoperating mines that had been closed about 50 years ago because of falling prices are described in detail. A profitable operation is considered very likely. Ha (1)

The Hydraulic Properties of Blast-furnace Slag (Die hydraulischen Eigenschaften der Hochofenschlacke) G. MUSSGNUG. *Mitt. Forsch. Anstalten Gutehoffnungshütte-Konzern, Oberhausen,* Vol. 6, July 1938, pp. 153-168; Aug. 1938, pp. 169-180. Original research. An exhaustive investigation was made into the properties and reactivity of blast-furnace slags produced in the manufacture of various types of pig Fe and the conditions under which it sets. The hardening of the rapidly-cooled, highly basic slag depends more on the temp. at which melted than on the chemical composition, the hotter the slag was melted, the better it hardens. Some properties are strongly influenced by the SiO_2/Al_2O_3 ratio; the hydraulic strength increases with increasing SiO_2 content, while the strength in air does not increase and shrinking decreases. Increasing Al_2O_3 content, although greatly improving hardening in water and air, also strongly increases shrinking. A rapid testing method is described that permits determination of the reactivity of high-basic slags within 12 hr., with good practical success. Tables of composition and equilibrium diagrams of slags are given. 23 references. Ha (2a)

3

The Sintering Process and Some Recent Developments. JOHN E. GREENAWALT. *Metals Tech.,* Vol. 5, Sept. 1938, T.P. No. 963, 22 pp. Practical. Modern practice of sintering, with especial reference to Fe ores, is reviewed. The best method is to place the material (mixed with fuel if S is low) on a grate, ignite from the top, blow air through the mass from the top, and maintain a vacuum under the grates. The increased efficiencies resulting from the vacuum are shown. In sintering Fe ore it is undesirable to form ferrous silicates. With the sinter now available better furnace operation results from the use of sinter than with the use of all lump ore. It is predicted that lime will be added to the fine ore to produce a self-fluxing sinter. JLG (2a)

4

Noteworthy Developments in a Blast Furnace Lining (Bemerkenswerte Neuerungen bei einer Hochofenzustellung) J. STOECKER & A. REIN. *Stahl u. Eisen,* Vol. 58, Sept. 8, 1938, pp. 965-970. Practical. Several innovations in a new blast furnace that gave a saving in material, more uniform operation and greater output are discussed. New cooling boxes were developed. These were made of Fe, smaller than usual, more numerous and spaced closer together. The boxes reinforced the lining, which could be built thinner, and maintained its contour well. The outer casing of the shaft was of welded steel plate. New tilting runners, slag ladles and blast furnace gas cleaning apparatus are shown. SE (2a)

5

New Problems in Iron Metallurgy and Coking (Neue Aufgaben bei der Eisenverhüttung und Verkokung) H. RÖCHLING. *Z. Ver deut. Ing.,* Vol. 82, July 30, 1938, pp. 899-901. Descriptive. Possibilities for developing a continuous process to utilize low-grade Fe ores and to reduce the quantities of slag in the blast furnace are discussed. An experimental plant is described in which the blast furnace Fe runs continuously to one end of a decarburizing and deoxidizing drum from the other end of which steel is removed continuously. Slag is taken off at the (liquid) Fe entrance. So far, 10,000 tons of V-steel have been made; vanadic acid was recovered from the slag. Ha (2a)

Calculating the Coke Consumption in the Blast Furnace in Advance (Die Vorausherechnung des Koksverbrauches im Hochofen) E. SENFTER. *Arch. Eisenhüttenw.,* Vol. 12, Aug. 1938, pp. 49-64. Practical. A Dogger ore with about 20% Fe requires about 125 kg. coke/100 kg. pig Fe. The heat required to heat the charge, the heat given up in wall losses and the heat of combustion of the coke were considered. Sample calculations are given for untreated Dogger ores and for various slags. SE (2a)

6

The Production of Ferrosilicon (Beiträge zur Ferrosilizium-Gewinnung) ERICH LIEBSCHER. *Metall u. Erz,* Vol. 34, No. 19, 1937, pp. 502-507. Discussion. Wrought Fe and P-free scrap Fe in the form of punchings, chips, etc., pure quartz and a special loose, porous and active coke, all of the best quality, are used. The viscous slag formed during melting facilitates the desired reactions. Casting recommendations are given. PCR (2a)

2b. Non-Ferrous

The Nkana Copper Refinery of Rhokana Corp., Ltd. ARCHER E WHEELER & HENRY Y. EAGLE. *Trans. Electrochem. Soc.,* Vol. 74, 1938, Preprint No. 19, 24 pp. Descriptive. This refinery in Northern Rhodesia, built at a cost of $2,000,000, is the first electrolytic refinery built in Africa. It has a capacity of 100 tons a day. Nkana blister Cu assays 99.3% Cu. The precious metal content is low. Because of its high Bi content (0.007%), which could not be effectively reduced by smelting, electrolytic refining was necessary. *Anode department:* The anode furnace is cylindrical, 30 ft. long and 13 ft. in diam. It delivers refined blister Cu, via a hydraulically operated pouring spoon, to a Walker wheel, 24 ft. in diam. Mould temperature is regulated by water sprays. *Electrolytic tank house:* The house contains 416 tanks, made of pre-cast concrete slabs lined with 6% antimonial sheet Pb. 26 of the tanks are used for preparing starting cathode blanks. A tank contains 32 anodes and 33 cathodes spaced 4.5 in. apart. All tanks are connected in series, and require 65-70 volts for the current supply of 9,000 amp. The current density is 15 amp./ft.^{2}, and the temperature is 56° C. 17-18 days are required for forming cathodes. A portion of the electrolyte is purified at regular intervals. *Furnace refinery:* The refining furnace for melting the electrolytic Cu is of the reverberatory type with a hearth 40 x 14 ft. and a capacity of 250 tons. The Cu is cast on a 38 ft. diam. Clarke type casting wheel. Finished shapes are delivered to an inspection conveyer. Three bars from each furnace charge are analyzed and conductivity measurements are made. AB (2b)

Interaction between Silicates of Nickel and Sulphides of Iron and Calcium in Melting. D. I. DERKACHEV & A. A. ZEIDLER. *Tsvetnye Metal.,* No. 7, July 1938, pp. 66-71. In Russian. Laboratory experiments confirmed the views previously published by W. JANDER (*Z. anorg. allgem. Chemie,* Vol. 172, 1938, p. 129) and other investigators in regard to the possibility of melting oxidized Ni ores with pyrite or sulphides of Ca in refractory furnaces. The reactions $NiSiO_3 + FeS \rightleftarrows NiS(Ni_3S_2) + FeSiO_3$ and $NiO + FeS \rightleftarrows NiS(Ni_3S_2) + FeO$ go almost completely to the right, the equilibrium constant for the first reaction being $0.49\ 10^{-2}$ to $0.84\ 10^{-2}$. Addition of CaO and CaF_2 has little influence on the constant. Addition of charcoal shifts the equilibrium to the right, i.e. toward slags poorer in Ni. Reaction $NiSiO_3 + CaO \rightleftarrows NiS(Ni_3S_2) + CaSiO_3$ goes to the right even more completely than the FeS reaction. These reactions go to the right both in oxidizing and neutral atmospheres; in reducing atmospheres the reactions are complete and the slags are free from Ni, *i.e.* all Ni is converted into sulphide form. 10 references. BND (2b)

Cathodic Processes in the Electrolysis of Cryolite-alumina Melts. A. I. BELYAEV. *Tsvetnye Metal.,* No. 7, July 1938, pp. 87-93. In Russian. Original research. Experiments were conducted to determine whether, in the electrolysis of cryolite-Al_2O_3 mixtures, the dissociation of Al_2O_3 and AlF_3 forms Al^{+++} ions, which are deposited on the cathode, or whether this is preceded by the deposition of Na, with the deposition of Al following as a secondary reaction. Decomposition potentials of melts of Na_3AlF_6 + 15% Al_2O_3, K_3AlF_6 + 15% Al_2O_3, and Li_3AlF_6 + 7% Al_2O_3 were in all cases equal (2.20 at 950° C. and 2.01 at 1080° C.), and thus not dependent on the nature of the cryolites used, indicating that the cathodic process is essentially the primary neutralization of Al^{+++} ions. The decomposition potentials of pure Na-, K-, and Li-cryolites at 1080° C. were 2.07 volts for Na_3AlF_6; 2.13 for K_3AlF_6, and 2.20 for Li_3AlF_6. BND (2b)

Trail Solves Its Sulphur Problem. S. D. KIRKPATRICK (Staff) *Chem. & Met. Eng.,* Vol. 45, Sept. 1938, pp. 483-485. Descriptive. Consolidated Mining & Smelting Co. of Canada, Ltd., now recovers elemental S from the gases obtained by roasting the Pb and Zn flotation concentrates. The gas is purified and SO_2 is reduced to S by incandescent coke. The product is the 99.99% brimstone of commerce. PRK (2b)

Important Facts on Molding Sands (Wichtiges über Giessereisande) *Giessereipraxis,* Vol. 59, June 19, 1938, pp. 243-245; July 3, 1938, pp. 263-265; July 17, 1938, pp. 283-286. Practical. Considers in detail all points of importance for suitable molding sands and the defects in castings unsuitable molding sands may cause, particularly the necessity of providing sufficient permeability. American preference for synthetic molding sands would be unjustified for German conditions, since they offer neither economic nor practical advantages. The requirements of synthetic molding sand-binders are discussed. Experiments with a new patented binder "Geko," marketed by O. Ullrich, Leipzig, permitting unlimited regeneration of old sand and reimparting plasticity to sands that have become unplastic, are outlined. The following table shows the improvement that may be obtained:

	Old, unfit sand	Same sand +1% "Geko"
Gas permeability	14.2	21.6
Compression strength, g./cm.²	337.0	940.0
Shearing strength, g./cm.²	103.0	220.0
Water content, %	8.38	8.38

Theoretical and Practical Significance of Graphitization in Cast Iron. E. Piwowarsky. *Foundry Trade J.,* Vol. 59, Sept. 8, 1938, pp. 181, 184. Review. Besides its good fluidity and machinability, gray cast Fe possesses certain specific properties that ensure its preferred position among casting materials, despite the keen competition of new materials on a light-metal or synthetic resin basis. These properties include wear-resisting capacity, high compressive strength, good vibration damping power, high notch strength, relatively high fatigue strength, elastic resilience, corrosion resisting properties, good adhesion of oxide and scale films, etc. etc. As it is nowadays generally possible to produce sand-molded cast Fe systematically with 3-3.3% C and 1-2% Si and with wall-thicknesses of 0.4-1.2 in. having strength of 24 tons/in.², it does not appear necessary to reduce the C content below about 2.7-2.8% for mechanically high-grade castings. Any further increase in the efforts solely in the direction of an increase in strength is not necessary and may damage the foundry industry. It is furthermore obvious that for many purposes where an unalloyed Fe will serve, an alloy cast Fe should not be stipulated. Cast irons with 2.7-3.4% C are and should remain the most important from the viewpoint of manufacture and use. Concerning deoxidizing ladle additions in the form of Fe-Si or Al alloys, the author observed in electric furnace melts a fairly constant increase in the strength figures. Under slags rich in lime or alumina, and with considerable superheating of the bath in the electric furnace, it is quite possible to attain tensile strengths of 19-24.5 tons/in.² with 3-3.2% C. According to W. O. Ruff (*Metals and Alloys,* Vol. 5, May 1934, p. MA 180) and P. Bardenhauer & A. Reinhardt (*Mitt. Kais. Whilhelm-Inst.,* Düsseldorf, 1936, No. 6) low-oxide silicate slags, particularly in the case of low-C melts, promote the formation of an exceedingly fine graphite eutectic, while slags richer in oxide tend to produce normal crystallization of the graphite without excessive supercooling. AIK (3a)

Gas in Steels. Experiments with Gases Discharged During Pouring (Gaz dans les Aciers. Expériences sur Gaz Degagés Pendant la Coulée) G. Moressée. *Rev. Universelle Mines,* Vol. 14, Sept. 1938, pp. 677-687. Research. Liquid converter steel contains 10-15 times its volume in gases (volume referred to normal temperature and pressure) which, in general, consist of ⅔ CO + CO_2, and ⅓ H and N. Experiments were made to determine the amount of gas escaping during pouring and the amount of gas remaining in the steel. The method of determination is described in detail and the results are summarized in the following table:

	Gas in l./ton of steel			Composition of gas, %		
	$CO+CO_2$	N_2	H_2	$CO+CO_2$	N_2	H_2
Bessemer steel, very soft, not killed	224.0	37.6	34.1	74.9	12.6	11.4
Bessemer steel, soft, not killed	149.6	47.6	6.6	62.3	23.0	3.2
Bessemer steel, soft, not killed, agitated	149.7	31.1	6.3	78.8	16.9	3.3
Bessemer steel, soft, killed	8.0	43.2	17.3	11.6	62.4	25.0
Open-hearth steel, soft, not killed	177.6	27.2	7.5	82.9	12.7	3.5
Open-hearth steel, killed	2.1	31.1	0.2	5.9	87.8	0.5
Bessemer steel, hard	0.2	4.9	0	3.3	86.8	0.0
Open-hearth steel, harl	0.8	16.9	0.5	29.8	67.7	2.1

Besides these gases, O_2 and CH_4 also have been found, but in very much smaller quantities. The gases have a very different rate of discharge: That of N_2 is most rapid at the beginning of pouring and then diminishes quickly; that of CO is small at the beginning, increases to a maximum and then diminishes again; H_2 behaves like CO_2, but the maximum is much less pronounced. This gives, for the same steels, in the order in which they appear in the table, as 6.79, 1.84, 6.58, 4.13, 18.93, 1.93, 5.66, and 1.05 l./ton. The time for the escape of the gases was measured, and given, in l./ton/min., 13.18, 14, 11.26, 3.98, 12.11, 3.70, 1.12, and 1.82 repectively. Ha (3a)

Heat Content and Heat Capacity of Slags of the System SiO_2-CaO-FeO. B. P. Selivanov & V. M. Shpeizman. *Metallurg,* Vol. 13, Feb. 1938, pp. 26-34. In Russian. 4 groups of slags were used: (1) 24-25% :SiO_2, 0-40% CaO and balance Fe oxides. (2) 30% SiO_2, 0-50% CaO and balance Fe oxides. (3) 40% SiO_2, 0-43% CaO and balance Fe oxides, and (4) 50% SiO_2, 0-35% CaO and balance Fe oxides. In each group the sum of CaO + FeO was constant. 2 heat content measurements were made below, 2 above, and one at the melting point. At temperatures up to the melting point, the heat content of various slags changes very little. By increasing the CaO to 20%, the heat content of the last 3 groups drops somewhat; a further increase of CaO from 20 to 50% causes a rise in the heat content. This was not observed in slags of the first group. Above the melting point the heat content of various slags is different because of their differing tendency to crystallize. All the slags consisted of crystalline and vitreous components. If the chemicial composition of the slag is nearly the same as that of an easily crystallizing chemical compound, then the heat content will increase with a rise in temperature. Slags that do not have this chemical composition, but crystallize easily, will have the same or a slightly lower heat content with a rise in temperature. Such behavior is due to the varying proportions of crystalline and vitreous parts. In general the heat content of the slags is not an additive function, but depends much on the mineralogical composition. The melting point of $2FeO.SiO_2$ was 1210°. BZK (3a)

Melting Tests with a Line Frequency Induction Furnace (Schmelzversuche mit einen kernlosen Netzfrequenzofen) G. Mars. *Stahl u. Eisen,* Vol. 58, Aug. 4, 1938, pp. 833-840; Aug. 11, pp. 865-868. Melting practice with 25 cycle line frequency induction furnaces and a similar vacuum furnace of about 3-ton capacity is described. There was no difficulty in melting even such fine scrap as thin sheet. Low frequency current is advantageous for heavy scrap and large furnaces; high frequency current for light scrap and small furnaces. The role played by bath agitation by the electric current is discussed. Calculations indicated the efficiency of the furnace was about 57%, this being about as good as for high frequency furnaces. No condensers were required, the furnaces being operated directly on the line current. SE (3a)

"HYDRIMET"

METALLIC

HYDRIDES AND METALS

PRODUCTS OF THE HYDRIDE PROCESS

URANIUM-NICKEL ALLOY

Uranium-Nickel Master Alloy containing 66-70% of Uranium free from carbon, silicon and aluminum, is recommended for addition to the ladle to introduce Uranium into special alloys.
Alloy containing 66-70% of Uranium melts below 1100°C (2012°F), has a specific gravity of 13, can be heated for a short time to red heat without oxidation, and is resistant to dilute acids. It sinks in the molten bath and alloys rapidly without loss of Uranium.

"HYDRIMET" PRODUCTS

Titanium Hydride	Powder 200-300 mesh
Zirconium Hydride	Powder 200-300 mesh
Titanium Metal	Powder 100-200 mesh
Zirconium Metal	Powder 100-200 mesh
Thorium Metal	Powder 100-300 mesh
Copper-Titanium Alloys	Ingots
Uranium Metal	Fused Pellets or Powder 100-200 mesh
Uranium Alloys 30% to 80% U	Ingots or Powder
Nickel Zirconium	Ingots or Powder
Nickel-Titanium Alloys—10% to 80% Ti	Ingots or Powder
Copper-Zirconium Alloy—10% to 80% Zr	Ingots or Powder

Until further notice, "Hydrimet" Copper-Zirconium Master Alloy will be supplied by P. R. Mallory & Co. Inc., of Indianapolis, Ind., who will produce this alloy under our process (patent applied for). Enquiries should be forwarded direct to that Company.

Patents issued and pending in the U. S. A. and Foreign Countries

Evolution of Gases from Rimming-steel Ingots. K. C. MCCUTCHEON (Am. Rolling Mill Co.) & JOHN CHIPMAN (Mass. Inst. Tech.) *Metals Tech.*, Vol. 5, Aug. 1938, 21 pp. Original research. Gases were collected from 18 in. x 39 in. ingots by covering the liquid steel in the mold with a welded hood of heavy sheet Fe, which was allowed to freeze into the rim of the ingot. Gases were led out through a steel pipe and rubber hose to a gas meter and sampling valve. Rate of flow was between 2½ and 5 ft.³/min. when the meter readings were begun, and evolution continued for a period of 30-40 min. Total gas evolved after filling the mold ranged from 36-to 74 ft.³, and it was estimated that between 20 and 40 ft.³ escaped during teeming. In general, less gas was evolved at 0.09% C than at lower percentages. The gas contained 80-92% CO, 2-14% CO_2, 2-6% H_2, under 3% N_2, and traces of hydrocarbons. As the C content increased the ratio of CO_2 to CO decreased. Samples from liquid metal in adjacent ingots were analyzed for C and O. The ratio of CO_2 to CO in the gas was proportional to the O content of the metal. The C-O product in the liquid metal was 0.0020-0.0028, compared to an equilibrium product of 0.0022 at atmospheric pressure. This indicates that the C-O reaction is very rapid. Gas and metal analyses were used to compute gas pressure within the ingot, which was found to be about 1.4 atmospheres immediately after pouring. Since the ferrostatic pressure in the lower part of the ingot exceeds this figure, the occurrence of the rim blowholes is explained by the inability of localized gas bubbles to grow against the applied pressure. In the upper part of the ingot, free evolution occurs and the bubbles are swept away. JLG (3a)

Desulphurizing Properties of Aluminum in Steel-making Processes. V. KARMAZIN. *Teoria i Pract. Metall.*, No. 5, 1938, pp. 23-30. In Russian. Original research. Solubility of Al_2S_3 in Fe was investigated by melting the Fe under Al_2S_3 + Al_2O_3 slags, and was found to be quite low. As it decomposes FeS completely, addition of Al can be used for desulphurization of steel in practice. Distribution coefficient between the metal and alumina-lime slags for Al_2S_3 is about 125, so that good desulphurization is possible, provided the metal is well deoxidized. Ten basic open hearth heats were killed with 10% FeSi and FeMn, treated with a Si-Mn-Al alloy and tapped 15-20 min. later. S originally present was cut 30-50%, from 0.025% to 0.010% and from 0.065 to 0.040% S, these being the limits of sulphur range. Al_2S_3 can be determined by decomposition with water and measuring the H_2O evolved. The apparatus and methods employed are described. (3a)

The Economic Importance of Centrifugal Casting (Die wirtschaftliche Bedeutung des Schleudergusses) W. HAKEN. *Giesserei*, Vol. 25, Aug. 12, 1938, pp. 395-401. Review. After a brief historical sketch of the development of centrifugal casting, its advantages are discussed. These include avoidance of losses through heads, risers and gates; the ability to produce tubular pieces; complete filling of the mold; and absence of segregation. Degasification and increase of nucleation are discussed and examples described for molds and tubular products. The usual composition of centrifugally cast Fe is about 3.4-3.8% total C (3.0-3.50 graphite), 1.6-2.5% Si, 0.4-0.7% Mn, 0.7-1.0% P, and 0.04-0.08% S. The most common position for casting heavy pieces is vertical. Ha (3a)

Slag Regulation in an Open Hearth Furnace. L. VLADIMIROV. *Stal*, Vol. 7, Dec. 1937, pp. 1-7. In Russian. The length of a steel heat is determined not by the time required for the chemical reactions but by the rate of heat absorption by the steel bath. This rate can be increased by reducing the thickness of the slag during the oxidation period. Theoretical considerations verified by practice show that the length of the heat is a hyperbolic function of the slag thickness, decreasing from 19 hrs. for 200 mm. to 4 hrs. for 25 mm. thickness in the case of a 150-ton furnace. Metal Castings (Ausschuss durch Gase im Schwermetallguss. Wege zur Verhütung) F. HÖHNE. *Giessereipraxis*, Vol. 59, Aug. 28, 1938, pp. 347-350. Practical. The effects of H, N, SO_2, O, CO, and H_2O vapor in castings of Cu, Ni and their alloys, particularly rising of the metal in mold and inverse ingot segregation. The remedies to avoid infiltration of gases in melt are discussed: (1) Protection of molten metal by slags, (2) oxidizing melting, (3) suitable furnace type, (4) proper selection of charge, and (5) necessary precautions in molding. If, in spite of the mentioned precautions, the metal should be gaseous, the following is advised: (1) Increased addition of P-Cu, (2) quieting before casting, (3) stirring of some gates or some pieces of Zn into molten metal or of Cl or N. The gas-sensitivity of various non-ferrous metals is touched upon. GN (3b)

MANGANESE ORE
METALLURGICAL AND DIOXIDE GRADES

Direct from newly discovered deposits in Australia.

Lowest Grade 50% Mn
Highest 90% MnO_2

Small percentage of impurities. Shipments from 50 to 10,000 tons

Mineral easy to grind

Analysis and samples on request

State your requirements and expert advice will be given.

Enquiries also invited for other base metals, Copper, Wolfram, Molybdenite, Tantalite.

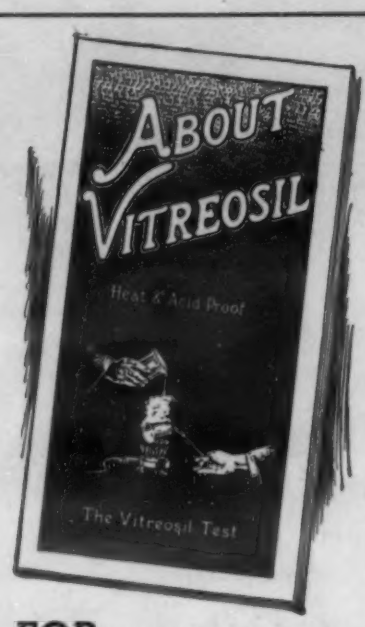
Non-ferrous Foundry Practice. XI. Design and Moulding Practice for Gunmetal. J. LAING & R. T. ROLFE. *Metal Ind., London,* Vol. 53, Sept. 16, 1938, pp. 273-278. Practical. The successful production of castings depends considerably upon their design. The designer should be fully aware of the foundry difficulties, as only rarely is a special design more advantageous than a design that is easy to cast. The design should avoid abrupt changes of section, avoid sharp corners by a generous use of fillets, and, whenever possible, should not have heavy masses so positioned that they are difficult to feed by ordinary methods. Gunmetal is one of the easiest metals to cast. Small castings are generally made in green sand, and medium to large size in dry sand. The preparation of a mold may be divided into 3 steps: Ramming, finishing and closing. The mold of a small spherical casting presents little trouble. It must be rammed hard but not hard enough to cause scabbing. A hollow casting is more difficult. The cope is as simple as with the spherical mold; the drag offers low resistance to scabbing, as the free escape of gas is restricted; a gas pressure under the mold face puts the surface in tension. Therefore, the drag half must not be rammed so hard as to impair permeability, but must be rammed sufficiently hard to preserve its shape. On small castings, these limits may be wide, but the larger the casting the narrower the limit. These limits may be increased by following certain precautions, such as: The moisture content of the sand must be low, or if the troublesome part of the mold is vented with a wire, it may be rammed harder; skin drying also helps. Molds and cores for bronzes do not usually require as much venting as with cast Fe. Mold surfaces liable to scab should be well vented. The successful production of most non-ferrous castings depends mainly upon correct gating, size and number of runners and risers. Feeding heads are employed chiefly on pressure castings, primarily to ensure sufficient feeding of the upper part of a casting, a secondary use being that of keeping the top face free of dirt. The design of the runner bush of small gunmetal castings is not of vital importance. It must be clean and free from loose sand. Gunmetal castings are usually run quickly, so that, in making heavy jobs, comparatively large runner bushes should be used to maintain a reservoir of metal and prevent the passage of dross down the gate into the castings. For small work, the use of runner plugs over the down gate is unnecessary if the metal is skimmed first. They are desirable for large jobs. Special care must be taken with their use to ensure proper seating and not permit leakage down the gate while the bush is being filled. For Part X see *Metals and Alloys.* Vol. 9, Dec. 1938, p. MA 704 R 5. RWB (3b)



A New Water Cooled Mold. Casting Non-ferrous Metals Horizontally. SVEN F. ERICHSEN. *Metal Ind., London,* Vol. 53, Sept. 9, 1938, pp. 251-252. Description of a new mold. The principle of water cooled molds has been applied for 25 yrs., during which the basic design has remained unchanged, with improvements directed toward prolonging the life of the mold rather than the quality of the product. Elimination of some of the disadvantages was attempted by incorporating Ni alloy steel cooling plates. These expand considerably when placed in contact with the molten metal, and the center of the slab is subjected to considerable pressure, thus reducing blowholes. The expansion of the Ni steel plate is so great that the decrease in volume in the mold is greater than the contraction in the volume of the cast metal, so that no after-pour is necessary. The Ni steel plates have a shorter life than Cu and are more difficult to keep clean, but slabs of improved quality are produced. To overcome the solidification disadvantages of the old type vertical mold, a new type horizontal mold was developed with good results. In pouring this mold, it is tilted sufficiently to allow the metal to enter smoothly. When there is enough metal in the mold to cover the bottom, it is returned to position, skimmed and covered to prevent oxidation. The base plate of the mold is Cu, water cooled. The frame is heated to ensure solidification proceeding upward from the base plate; this scheme also eliminates metal sticking to the side. By this method the impurities only travel the thickness of the slab to reach the surface and are not entrapped in the center, as in vertical casting. Since the solidification takes place uniformly, no after-pour is necessary. The waste head is also eliminated. Time required for solidification may even be shorter than in vertical molds. The horizontal mold is suitable for most metals and has been used for Cu, brass, bronze, Zn, Sn, Ni, Ni silver, Al and its alloys. RWB (3b)

Cause and Prevention of Spoilage with Green Sand Heavy Metal Castings (Giessausschuss bei Schwermetallnassguss, Ursachen und Beseitigung) E. HELLMANN. *Giessereipraxis,* Vol. 59, Aug. 14, 1938, pp. 327-330. Practical discussion of a suitable choice of molding sand, properties required, sand preparation, stressing in particular the necessity of using, in sand mix, powdered coal of first class quality (lignite is unfit, due to too-high ash content). Examples of defective castings resulting from the use of unsuitable molding sand are considered. Correct arrangement of parts in mold, gating technique, application of too large flasks, proper ramming and core making are also considered. GN (3b)

Magnesium Foundry Practice. W. C. DEVEREUX. *Foundry Trade J.*, Vol. 59, Sept. 22, 1938, pp. 218-219. Review. Melting practice, green-sand castings, sand preparation and control and mechanical properties are discussed. Mg is usually melted in steel
1 crucibles in oil-fired furnaces, although coke furnaces are sometimes preferred. Mild steel does not withstand the action of the fluxes and deteriorates rapidly. The steel should have a low Ni content because of the marked tendency for Mg to absorb Ni from the crucible. Cr and Co are not easily absorbed. It is possible, with extreme care, to melt Mg in a crucible with a closely fitting lid without the use of a flux, depending merely on an atmosphere of sulphur vapor for protection against oxidation. The method is, however, unsatisfactory, and superior results have been
2 produced by the use of fluxes. In German practice 2 fluxes are used (British patent Nos. 219,287), one having a relatively high and the other a low melting point. The metal is heated to a temperature of 800°-850° C. and then cooled to the casting temperature, which is approximately 700°-720° C., the object of the pre-heating before melting being to refine the grain size of the final casting. At the present time it is possible to make satisfactory castings in green sand by the use of inhibitors added to the sand to prevent burning of Mg. In German practice 5-10% S
3 and boric acid are added to the sand, with very good results. In British practice ammonium-bifluoride is used, and when the molten Mg comes in contact with sand containing this fluoride, a coating of insoluble magnesium fluoride is formed on the metal and aids in preventing burning and corrosion. Mg alloys with Al, Mn and Zn are amenable to heat treatment. The heat-treatment of Mg is difficult, owing to the fact that there is a tendency for the alloys to catch fire. The German method consists of carrying out
4 the heat-treatment in a bath of mixed dichromates or in an electric furnace in which there is an atmosphere containing sulphur dioxide. AIK (3b)

Pulverized Fuel for Lead Melting. Automatic Manufacture of Accumulator Plates. *Metal Ind., London,* Vol. 53, Sept. 2, 1938, pp. 219-222. Descriptive. Pulverized fuel has been used for firing furnaces for ferrous work for years, but only recently for non-ferrous. Pulverized fuel furnaces are now being used to replace oil-fired for Pb melting pots, and effect economies in fuel
5 costs of about 45-50%. Such installations are clean and give very fine temperature control. The lower the ash and water contents of the coal the better, from the point of view of furnace efficiency and cleanliness. Coal of smaller slacks than ¾ in. cubes are not recommended. In normal practice, pulverization in order to give 80% —200 mesh is found to answer all requirements. The Pb is melted in Fe pots set on top of the furnace. The burner is fitted at the bottom of the furnace, and an
6 average of 12 lbs. of coal per hr. is used. There seems to be no reason why this process should not be developed and extended to the melting of higher melting point metals than Pb. Its possibilities in the non-ferrous metal industry are manifold and demand further investigation both by the users and the makers of the pulverized fuel plant. RWB (3b)

Crystallization of a Steel Ingot. A. K. ZHEGALOV & V. M. TAGEEV. *Metallurg,* Vol. 13, Feb. 1938, pp. 35-49. In Russian. Original research. During the pouring of steel there is formed
7 a thin surrounding crust consisting of very small crystals. The next stage is the formation of a zone of columnar crystals that are oriented in the direction of the heat loss. The slowing down of the crystallization is due to the existence of a "bag" of liquid metal (thermal center). The location of the "bag" depends on the mold shape and cooling conditions. The existence of such a center for a long time enables the non-metallic inclusions to rise and collect in the upper part of the ingot. The crystallization of
8 subsequent volumes of liquid steel differs from the crystallization of the oriented zone. When the mother solution reaches the solidification temperature the crystallization speed increases, the capacity of the mold to accumulate heat decreases, the heat stream loses its previous direction and, as a result, there is formed a zone of disoriented crystals. The various stages of crystallization occur with differing intensities, depending on the shape of the mold. BZK (3b)

9 **The Influence of Melting Conditions on the Structure and Mechanical Properties of Secondary Aluminum Alloys** (Ueber den Einfluss der Schmelzbedingungen auf die Struktur und die mechanischen Eigenschaften von Umschmelz-Aluminium-Legierungen) P. RÖNTGEN & H. WINTERHAGER. *Metallwirtschaft,* Vol. 17, Oct. 7, 1938, pp. 1045-1051. Review plus original research. The literature and patents from 1930 to early 1938 on the refining of secondary Al are reviewed. The influence of fluxes and various scavengers as well as type of furnace on the microstructure
10 and physical properties of remelted secondary Al-Cu-Mg, Al-Mg, Al-Si-Mg and Al-Cu-Ni was studied. An induction furnace gave better results than a gas-fired furnace. Of the scavengers, Cl and N seemed to be the best when the material had previously been treated with a flux. $PbCl_2$ is a powerful cleansing agent for the Al-Si-Mg alloys. GA (3b)

$30.00 a month saved

Cast-to-shape Dies. *Steel,* Vol. 103, Aug. 15, 1938, pp. 62, 64. Descriptive. Strenes metal, a Cr-Ni-Mo alloy iron is used primarily for cast-to-shape forming and drawing dies. It has a minimum tensile strength of 50,000 lbs./in.^{2}, transverse strength of 4,000 lbs., and deflection factor of 0.23, and can be heat treated to a hardness of 525-550 Brinell or 55-60 Rockwell C and to a tensile strength of 75,000 lbs./in.^{2} It is close-grained, takes a high polish, and has excellent graphitic surface lubrication. For die service, it is made in types B and C. Latter is the extremely hard, long-life type. B is slightly softer grade used where long service is less important and is not recommended where maximum hardness is required. This alloy iron saves 30-50% in costs by reducing or completely eliminating finishing, and dies need be polished and stoned only 1/3-1/6 as often as usual. Long life is illustrated by refrigerator top die that is still in good condition after making 750,000 parts. In addition to dies, this iron is used also for its abrasion resistance in sand and gravel chutes, coke crushers, steam-hammer sleeves, and dredging-pumps. This has resulted in 3-4 times usual life. MS (D-4)

The Layout of a Metal Plant. Planning of a Medium Sized Rolling Mill. A. L. MOLINEUX. *Metal Ind., London,* Vol. 53, Oct. 7, 1938, pp. 329-334. Descriptive. The author's experience in the planning and completion of a rolling tube and wire mill of medium size is described, with extensive details as to all of the most important equipment and machinery in the mill. The essential features were: All mills are on one level, each mill having easy access to and from the pickling and annealing shops and to and from each other; auxiliary machinery is grouped to leave wide gangways and ample working room; all heavy machines are independently driven to allow any unit to be run or shut down as required; very few partitions or dividing walls are present, which allows for ease in supervision; and, as far as is possible in an "all-purpose" mill, everything is handled mechanically and in as large units as possible. RWB (E-4)

Some Characteristics of Wire and Their Relation to Cold Heading. H. L. HOPKINS. *Wire & Wire Prod.,* Vol. 13, Oct. 1938, pp. 521-528, 595. Descriptive. The present methods of cold-heading and upsetting, and the influence of them on the surface finish are discussed at length on the basis of publications on this subject. A very important point is the characteristic of the wire between the yield point and point of rupture, as this has a direct bearing on the upsetting process. Grain growth must be prevented as much as possible; by drawing the material beyond the point of critical strain the range in temperature that will produce grain growth in later heat treatment is materially decreased. A table of physical properties of normalized cold drawn wires is appended. 6 references. Ha (D-4)

Influence of Cutting Fluids on Metal Cutting. FRANK J. OLIVER (Staff) *Iron Age,* Vol. 142, Oct. 13, 1938, pp. 141-142, 144, 148, 150-157. Summarizes research work of the special committee on cutting of metals of the American Society of Mechanical Engineers, and includes some hitherto unpublished tests. Traces the accumulation of scientific proof that the chief attribute of cutting fluid is to cool the tool and work, rather than to act as a lubricant at the point of contact. Evaluates the results of research from the point of view of industrial applications. VSP (G-4)

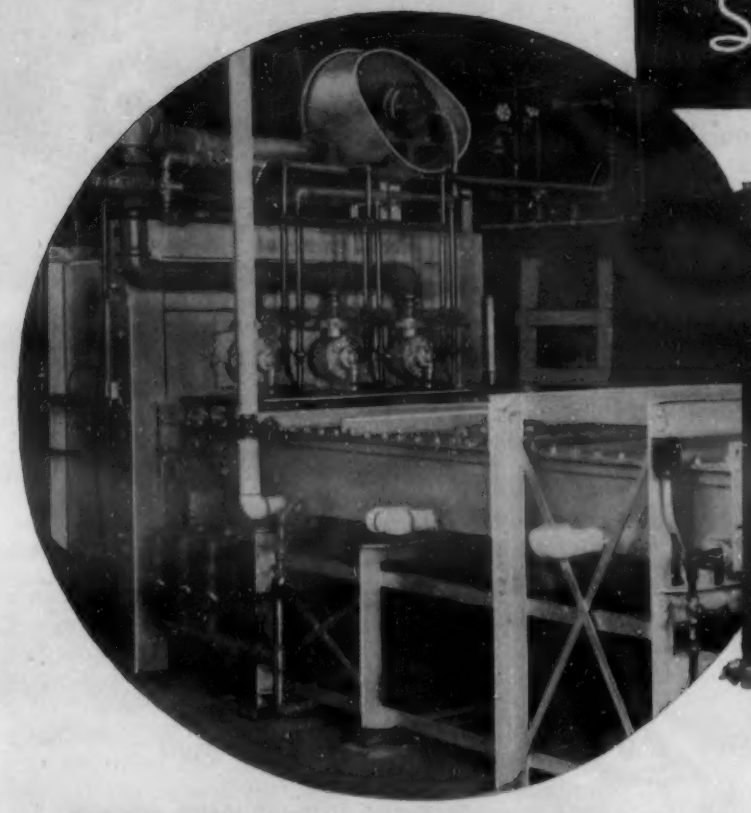
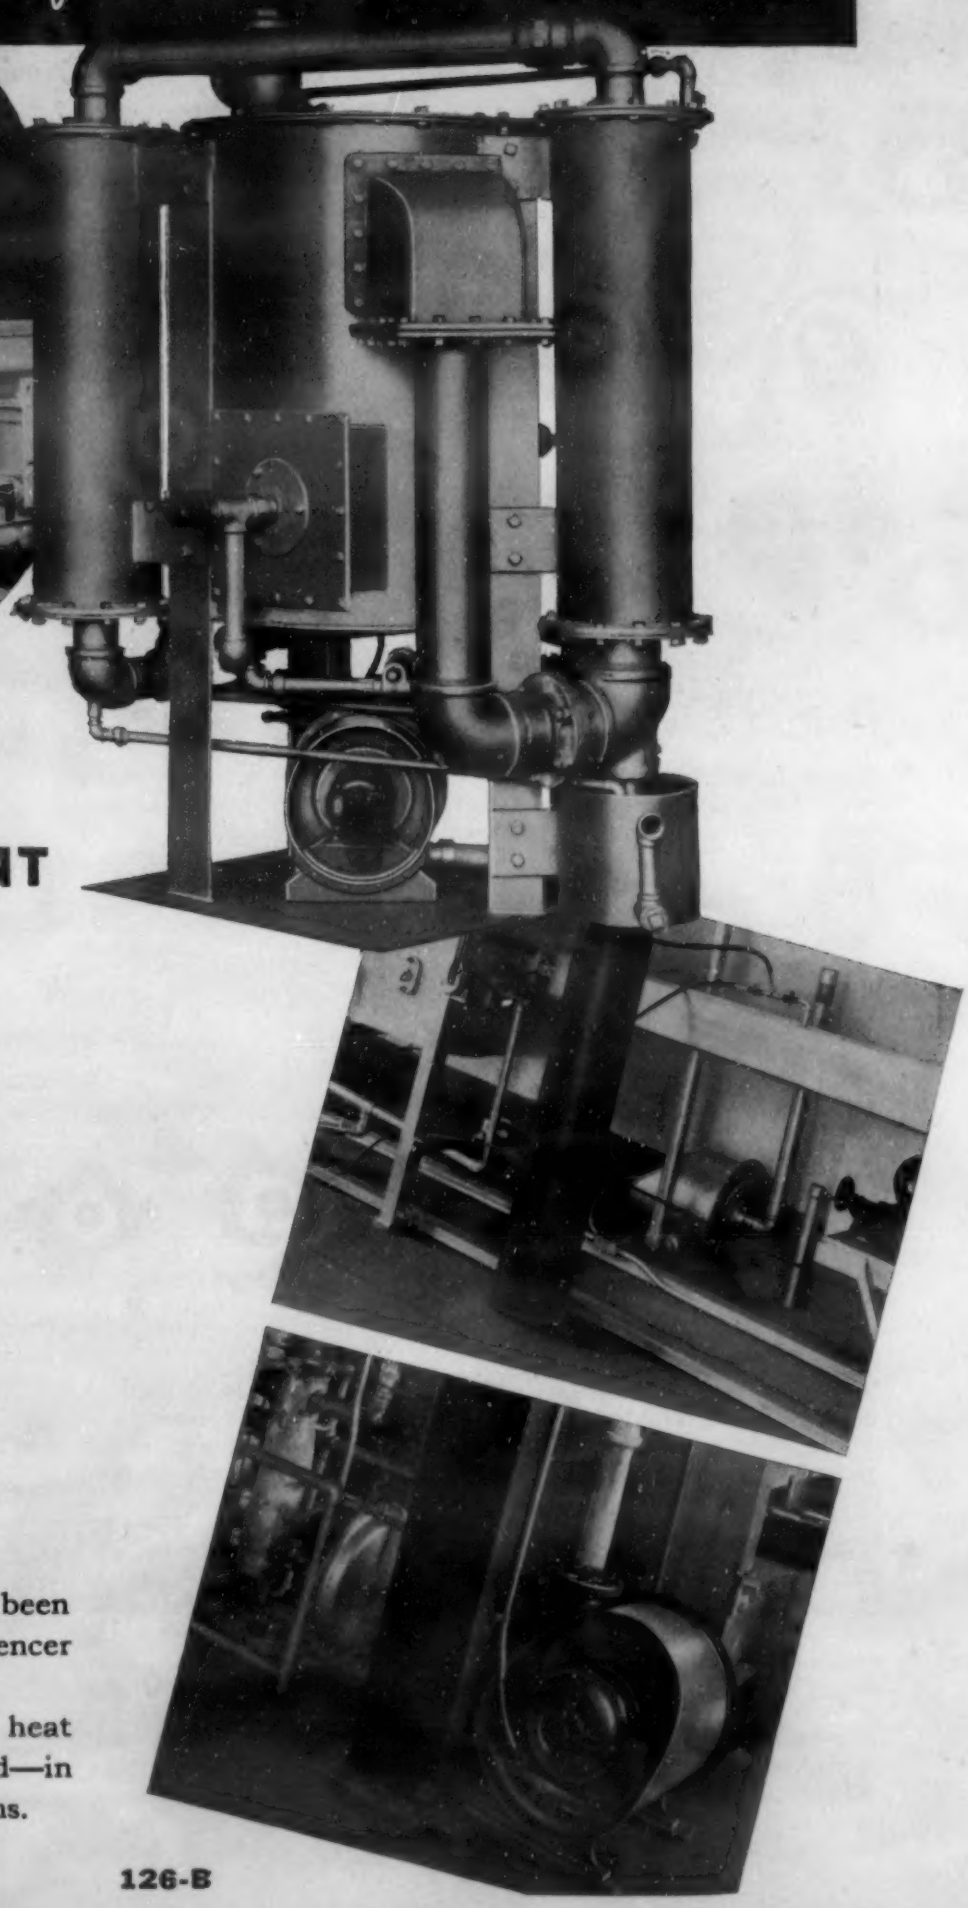
Spreading during the Flat Rolling of Round Steel Wire (Die Breitung beim Flachwalzen von Runddraht aus Stahl) A. POMP, H. HÖHLE & W. LUEG. *Stahl u. Eisen,* Vol. 58, Sept. 1, 1938, pp. 937-943. Original research. The effect of various cold rolling conditions on the "spreading" of different compositions of C steel wire was studied. Spreading increases with the degree of reduction; it is greater in larger diameter rolls. The C content and structure of the wire were without effect. Lubricating the wire and the rolls gave less spreading. The number of passes had little effect. Nomographs are included, showing what the original diameter of the round wire should be to give the desired dimensions after flat rolling. SE (E-4a)

Pressure Machining. *Steel,* Vol. 103, Aug. 8, 1938, pp. 54-55. Describes "Coldflo" process for producing parts comparable in accuracy of dimension and form to those machined from a solid piece of stock. The outstanding advantage is low costs involved. Other advantages are: High strength and hardness, good grain flow, smooth surface finish and an absence of scrap. Bar stock is usually used, and this is flowed cold under extreme pressure to fill contours and cavities of die. In some cases a subsequent draw or forming operation is necessary. Conventional embossing presses of knuckle type are used. Dies are designed and constructed with great care and must have a smooth finish. For general use, they may be made of any good grade of H_2O-hardening cold-header tool-steel. In some cases, cemented WC dies are excellent. Most satisfactory steels for this process appear to be hot-rolled SAE 1010 and 1020, although steels up to 0.45% C and 0.90% Mn have been worked successfully. Non-ferrous metals, particularly brasses, are readily worked. Normalizing removes strains set up if they are objectionable. MS (D-4a)



Wire Metallography. B. L. MCCARTHY (Wickwire Spencer Steel Co.) *Steel,* Vol. 103, July 11, 1938, pp. 54, 56-57. Review. Application of metallography to wire manufacture is comparatively recent. Presents examples showing how it helps to prevent mill troubles and to assure uniform high quality. McQuaid-Ehn test has established value of controlled grain size of steel to be drawn into wire. For maximum efficiency and uniform high quality, best results are obtained with coarse-grained material. If a duplex structure is present, patenting treatment can not be adjusted to take care of fine and coarse grain sizes in same rod. Fine grain areas produce thicker cementite plates than coarse grain areas with same rate of cooling. Structure of patented wire, formerly regarded as sorbitic, consists of thin plates of ferrite and cementite. Plate-like formation of Fe_3C is best for wiredrawing. Properly annealed low-C wire has spheroidized particles of globular cementite. In heat treating oil tempered spring wire for valve springs, speeds and temperature should be regulated to produce minimum austenitic grain size. MS (D-4a)



Investigations on the Drilling Properties of Plain Carbon Steels (Bohrbarkeitsuntersuchungen an unlegierten Stählen) H. JANSEN. *Maschinenbau Betrieb,* Vol. 17, Sept. 1938, pp. 455-456. Original research. The C content influences the drilling properties only indirectly, through its effect on the microstructure. The eutectoid carbide of normalized steel dulls the edges of drills rapidly; the machinability is thus reduced with increasing percentage of pearlite. In hyper-eutectoid steels with rather hard pearlite matrix, the ability to hold cutting power is not so markedly reduced by the increase of cementite. Hardly any influence of the C content is noticeable in fully annealed materials. This is explained by the fact that the hard carbide globules are able to back out into the soft pearlite. For shop practice the C content is, therefore, not a good criterion. There is, however, a definite relation between Brinell hardness and the drilling ability factor that holds for the normalized and annealed states. RPS (G-4a)

The Effect of Sheet Width in the Cold Rolling of Steel Sheets (Der Einfluss der Blechbreite beim Kaltwalzen von Stahlblechen) H. BOHR. *Stahl u. Eisen,* Vol. 58, Aug. 18, 1938, pp. 888-890. Original research. Cold rolling of low C sheets of different thickness revealed the relation between varying width of sheet and percentage reduction in thickness, the wider sheet showing less reduction. In austenitic stainless steel sheet, tests showed that with constant rolling pressure the reduction does not change uniformly with the width. SE (E-4a)

Jones and Laughlin's New 96 in. Continuous Hot and Cold Strip Mill. *Iron Steel Engr.,* Vol. 15, Jan. 1938, pp. J-L 1-17. A detailed description is given of the equipment and operating procedure. The entire set-up is covered, including slab supply, furnaces, hot mill, motor room, plate finishing, blue annealing department, coil pickling, cold mills, annealing, cold finishing, galvanizing, lubrication, cranes and service department. A summary of the connected power load is given, totalling 55,222 kv-a. at 6600 volts. A blue-print of the plant lay-out is included. REB (E-4a)

Spencer Turbos at Work

SPENCER TURBOS ON ROCKWELL EQUIPMENT

The illustrations show a few of the many W. S. Rockwell Company special atmosphere installations in service with air furnished by Spencer Turbos.

They say:

"Sure, we use Spencer Turbos and have been using them since the "Gay Nineties."

"We like them because we can put them in and forget them."

● PROGRESS—in oil and gas fired equipment has been accelerated every year by new developments in Spencer Turbo-Compressors.

Working closely with the leading manufacturers of heat treating equipment, Spencer has everything required—in volume, pressures, capacities, and physical dimensions.

5·HEAT TREATMENT AND HEATING

Aging, Annealing, Carburizing, Hardening, Malleableizing, Nitriding, Normalizing, Surface-Hardening and Tempering. Furnaces, Soaking Pits, Refractories, Atmospheres, Fuels and Auxiliaries.

O. E. HARDER, SECTION EDITOR

Selection of Refractories. B. THOMAS. *Iron & Coal Trades Rev.*, Vol. 137, Oct. 7, 1938, pp. 537-538. Practical review. Factors in selecting a refractory are discussed on the basis of 3 typical furnace operations. Low temperature furnaces for billet-heating, light forgings, etc. from 900° to 1200° C. may advantageously use a "Stourbridge" brick of which 4 typical analyses are given:

	A	B	C	D
Silica	60.52	69.76	58.20	53.80
Alumina	33.81	25.56	34.88	39.21
Iron Oxide	2.22	1.79	3.19	2.72
Titanium Oxide	1.14	1.00	1.90	1.60
Lime	0.65	0.60	0.57	0.30
Magnesia	0.51	0.38	0.51	0.71
Alkalies	1.15	0.85	0.71	1.35
Ignition loss	....	0.06	0.20	0.21

These furnaces are fired either mechanically or manually with solid fuel. High-temperature furnaces for 1750°-1770° C. are heated automatically with pulverized fuel or mechanically stoked solid fuel. Typical analyses of useful refractories for this service are:

	A	B	C
Silica	53.51	51.62	51.29
Alumina	42.44	42.44	42.00
Iron Oxide	2.60	1.89	2.65
Titanium Oxide	1.10	1.47	3.11
Lime	0.40	0.41	0.18
Magnesia	0.50	0.29	0.21
Potash	0.10	0.62	0.63
Soda	Trace	0.22	0.20

For steel-heating furnaces where slagging is a predominant danger, a spinel-base brick is recommended; 2 types are given for temperatures up to 1450° C., used for heating heavy forgings, etc.:

	A	B
Magnesia	35	39
Chromic Oxide	25	24
Alumina	17	16
Iron Oxide	14	14
Silica	7	5
Refractoriness under load	1560° C.	1600° C.
Porosity	19%	22%

The selection of fuel to be used, and the applications of thermal insulation in metallurgical furnaces are discussed. The most commonly used materials for this purpose are diatomite and diatomaceous silica (melting point, 1590° C) The methods of preparing mixtures and building furnace walls are described. Ha (5)

Remote Temperatures. *Steel*, Vol. 103, Sept. 19, 1938, pp. 63, 141-142. Description of "Rayotube," developed by Leeds & Northrup Co., for determining temperatures of hot objects without contacting or being adjacent to work. In the wide-angle type, which measures average temperature of a comparatively large area, energy from hot body passes through an opening in tube end and is focused upon thermopile element at far end of tube by means of a mirror. When used for measuring furnace temperatures, the instrument is held outside furnace wall and focused upon closed end of a target tube mounted in furnace wall. Narrow-angle type, used for indicating temperature over very small areas, has a lens to focus radiation from hot body upon thermopile at far end of tube. This has the appearance of a telescope mounted outside the furnace and focusing through a hole in the wall on work in the furnace. Temperature differences between furnace and work are eliminated from the control system, increasing accuracy. This device may be used where thermocouples are not practical. MS (5)

Refractory Service Increased Through Study of Problems. S. M. SWAN (North American Refractories Co.) *Foundry*, Vol. 66, July 1938, pp. 29-30, 70. Practical. The following are steps necessary: (1) Determine most likely destructive force acting on refractories; (2) determine other contributing factors; (3) check service factors and their relation to problems; and (4) evaluate data obtained. Considers failures caused by softening at high temperatures, structural changes at high temperatures, spalling, abrasion, slag attack and erosion. VSP (5)

Base-metal Thermocouples: Their Characteristics. M. R. MANDLEKAR & H. N. BANERJEA. *J. Soc. Chem. Ind.* (Trans. & Comm.) Vol. 57, Aug. 1938, pp. 276-278. Original research on the properties of various thermocouple elements for the temperature range 0-800° F. Calibration curves are shown, based on millivoltmeter readings at 50° C. intervals, for the following couples: Ni-Cr-Fe/constantan; Cu/constantan; Fe/constantan; Ni/constantan; Ni/Ni-Cr-Fe; Cu/Ni; Ni/Fe; Cu/Ni-Cr-Fe; Cu/Fe; Fe/Ni-Cr-Fe. Thermocouples with constantan gave a wide e.m.f., but the Fe/constantan couple alone gave a straight line temperature-e.m.f. relationship. The curves for Ni-Cr-Fe/constantan and Cu/constantan, however, approached a straight line very closely, especially above 150° C. These 3 couples can be recommended for frequent and reliable use, but the Fe/constantan and Cu/constantan couples must be restricted to low temperature applications owing to the susceptibility to oxidation of Fe and Cu. Ni thermocouples show irregularity in the e.m.f. curves over the range 250-400° F., but the irregularity is overcome by combining Ni with constantan. Neutral points for Fe/constantan and Cu/Fe couples were determined at 205° F. and 275° F., respectively. AAA (5)

An Internally Heated Electric Salt Bath Furnace—Some Users' Experiences. FRED P. PETERS. *Metals and Alloys*, Vol. 9, Aug. 1938, pp. 183-188. Practical description of Ajax-Hultgren salt bath furnaces installed and operating in 3 plants making machine tools, hardware and engraved dies, respectively, with most satisfactory results. The salt bath in these furnaces is heated by the resistance of the bath to the current flowing between one or more pairs of immersed electrodes. The electromagnetic field produced causes a stirring action in the molten salt that results in very uniform temperature distribution throughout the bath, though the electrodes are located outside the working space. The chief advantages found by these users are: Improved quality and uniformity of work, longer pot life due to internal heating, flexibility, cleanliness and comfort in the hardening room. WLC (5)

Foundry Refractories. W. J. REES. *Foundry Trade J.*, Vol. 59, Sept. 29, 1938, pp. 239-240. Although certain of the siliceous materials have a comparatively low refractory value in comparison with aluminous materials and high-silica materials, such as silica brick used in the open-hearth furnace roof, yet they may show some useful properties. Because of their comparatively low refractory value they will tend to glaze over at only moderately high temperatures, and the production of the glaze may retard corrosion and erosion. Thermal changes, physical changes, raw materials for cupola ganister, the bonding material, fireclay considerations, influence of crushing, water additions, general properties, etc., are discussed. AIK (5)

Experimental Determination and Calculation of Combustion Temperatures and their Application to City Gas (Experimentelle Bestimmung und Berechnung der Verbrennungstemperaturen und ihre Anwendung auf das Stadtgas) G. RIBAUD. *Gas-u. Wasserfach*, Vol. 81, Sept. 10, 1938, pp. 661-666. Review plus research. Tables are given and formulas developed to calculate the combustion temperature, theoretical and actual, from the heat contents of the gases involved. Tables show the combustion temperatures for H_2, CO, CO + H_2, CH_4, C_2H_2, C_2H_6, C_3H_8 and C_6H_6. Ha (5)

Electric Furnace Design. ROLLAND R. LAPELLE (Continental Ind. Engrs., Inc.) *Steel*, Vol. 103, Sept. 19, 1938, pp. 44-46, 48, 127-128, 130, 133. A summary of methods of calculation, with numerical values in form of curves and tables, affording a simplified system for design of electric furnaces for heating metals within the temperature range 450°-2100° F. All figures are reduced to electrical units. Curves for total losses show actual losses obtained by test on a large number of typical furnaces under operating conditions. MS (5)

Refractory Products in the Steel Mill (Les Produits Réfractaires dans les Aciéries) D. PETIT. *Rev. Mét.*, Vol. 35, July 1938, pp. 296-309. Discussion of refractories used in basic open-hearth, Bessemer, arc and pit furnaces, with emphasis on the increasing use of magnesite and chrome magnesite. Suitable construction of chrome magnesite roof for an open-hearth is described. Refractories and design of ladles are considered in detail. See also *Metals and Alloys*, Vol. 9, Nov. 1938, p. MA 648 R/5. JZB (5)

This announcement concerns a heat-producing method which has been successfully applied to a variety of industrial heating processes.

The method purposely makes use of the "catalytic" effect of highly incandescent surfaces on completeness and speed of combustion. The results are: a HIGH rate of radiation; the combustion chamber IS the burner; ONLY products of combustion enter the furnace chamber.

Applications in furnaces and ovens cover a range of chamber temperatures from 300° F. to 2400° F. The ability of the method to produce temperatures ranging to 2900° F. is well established.

Uniform heat distribution; rapid heating; simplified and compact construction for furnaces and ovens; better atmosphere control; operating economy; safety—these advantages can be demonstrated.

The purpose of this announcement is to arrange with executive, designing and operating men—now concerned with processing of metals—for an exchange of information dealing with specific metal-heating processes.

Bulletin No. 811 provides essential details of the manner in which the radiant heat is generated, including explanatory diagrams, photographs, dimension drawings and fuel-consumption data. Copies are available for the men within your organization who want to have literature at hand covering new processing developments.

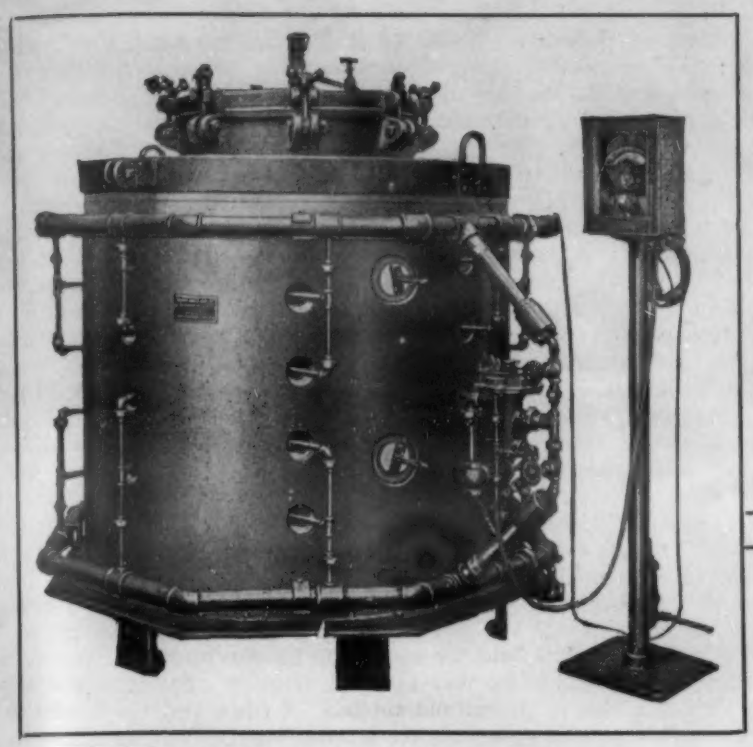
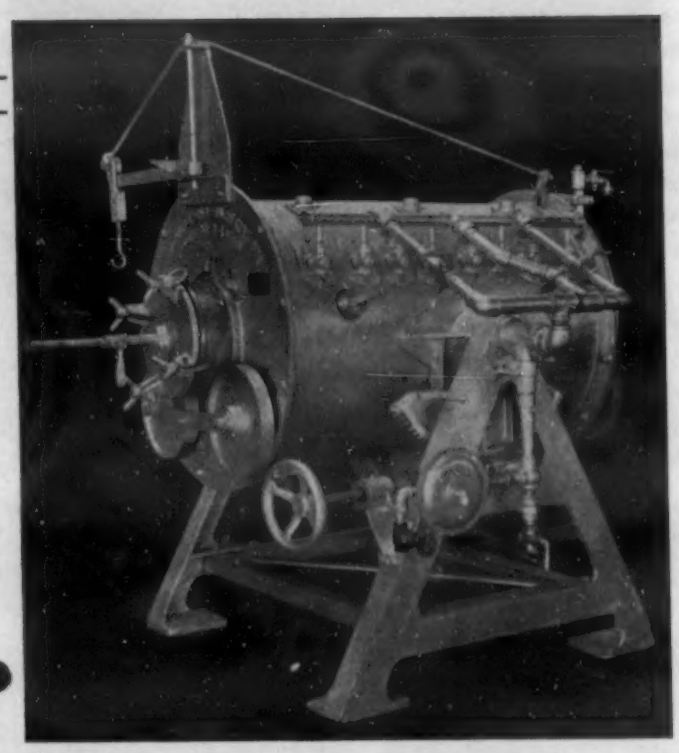
1 **Gases for Controlled Atmospheres—Requirements for Purification.** E. E. SLOWTER & B. W. GONSER (Battelle Mem. Inst.) *Metals and Alloys,* Vol. 9, July 1938, pp. 163-168. Original investigation. Discussion of previous work on the harmful effects of moisture and CO_2 in protective gas atmospheres (*Metals and Alloys,* Vol. 9, July 1938, p. MA 424L/2) shows the difficulty of removing the last traces of CO_2. The present article determines the limiting amount of CO_2 that can be tolerated, and the utility of small additions of CH_4 in counteracting CO_2. A dry charcoal 2 producer will yield 32% CO and 0.5% CO_2, which is decarburizing to 0.70% C (and higher) steel. The addition of 1.0% CH_4 reduces decarburization to a negligible amount. In partially-burned fuel gas atmospheres a CO_2 content of 0.2% seems to be the equilibrium value; the gas, if it originally contained 0.2% CO_2, remains unchanged in composition after passing through the furnace. Additions of CH_4 displace the character of the gas only slightly in the direction of carburization. The requirements for purification thus appear to be elimination of H_2O and a reduction of 3 CO_2 and H_2 content to such values that any H_2O formed is counteracted by the presence of CH_4. For dry producer gas, 0.5% CO_2 and for partially burned fuel gas 0.2% CO_2 can be tolerated, and an atmosphere produced that is non-decarburizing to high C steel with addition of small amounts about 1.0% of CH_4. H_2 with small amounts of CO_2 made neutral to high C steel with CH_4 will be more carburizing to low C steel than dry producer gas. This is also true of H_2-N_2 gas that is neutralized with CH_4 to overcome the decarburizing effect of H_2. WLC (5a)



4 **Factors Affecting Grain Growth in Annealed Rivets.** R. W. SANDELIN. *Wire & Wire Prod.,* Vol. 13, July 1938, pp. 344-353; Aug. 1938, pp. 399-404; Sept. 1938, pp. 455-458. Original research. The treatment of low-C steel rivets required to obtain a softness sufficient for easy upsetting and yet to produce sufficient strength is investigated and the structural changes involved are discussed in very great detail. Abnormal grain growth in annealed low-C rivets results principally from the combined effects of extent of cold-working on the wire, and temperature and duration of the 5 annealing process. Grain coarsening in heat-treatment occurs mainly in the outer portions of the shank, while under the head a relatively small section of smaller size grains is formed. The effects of exaggerated grain growth are eliminated with resulting grain refinement by heating the rivets to 1650° F. or higher. As the strain existing in a rivet is a function of the amount of reduction by drawing, it is possible to adjust the amount of cold-working to a degree where no grain coarsening will occur in subsequent annealing operations. The ill effects of grain coarsening do not 6 make themselves felt until the whole or nearly the whole shank section is affected by it, when strength is somewhat reduced. Numerous microphotographs and hardness curves illustrate the article. 9 references. Ha (5a)

Effect of Heat Treatment on the Yield Point of Special Steels. N. YAMAMOTO. *Nippon Kinzoku Gakukai-Si,* Vol. 2, July 1938, pp. 341-351. In Japanese. Original research. The yielding phenomenon was studied with low Ni-Cr steels, 3% Ni-Cr steel, Ni-Cr-Mo steel, Cr-Mo steel and C steels. When low Ni-Cr steel 7 and 3% Ni-Cr steel are tempered at about 70° C. below the Ac_1 point, the stress-strain diagram shows the same form as that of low-C steel, but when those steels are tempered at about 20° C. below the Ac_1 point, no yield point could be observed. Yielding takes place after a lower tempering temperature as C content increases, and the form of stress-strain diagram does not change with length of heating time at tempering temperature nor by cooling velocity after tempering. The yield point of Ni-Cr-Mo steel and 8 Cr-Mo steel does not disappear after tempering just below the Ac_1 point. Mo seems to prevent the disappearance of yield point. The yield point of the C steels does not disappear by tempering just below the Ac_1 point. Low Ni-Cr steel double-quenched and tempered also shows yielding phenomenon. After low tempering temperature, yielding phenomenon in mildly quenched Ni-Cr and low Ni-Cr steel disappeared. NS (5a)

Flame Softening of Cut Surfaces on Strong Steels. HERBERT H. MOSS. *Metal Progress,* Vol. 34, Aug. 1938, pp. 141-146. 9 Practical. The structure and hardness of structural steel plate is not as severely altered by flame cutting as it is by either shearing or friction cutting. The ductility and toughness is not appreciably affected by torch cutting; torch cutting definitely improves the toughness. This holds true with all low C steels, but with respect to the air hardening steels and higher alloy steels, a hardening effect is produced which is overcome by flame softening by means of a multiple flame follow-up torch. The thickness of the plate being cut will depend upon the size of the post heating flame 10 needed to give maximum softening effect; the thicker the plate the larger the annealing flame should be. For air hardening grades it is essential that this post heat does not exceed the critical point. Proper flame cutting operations will cause grain refinement at the cut edge. WLC (5a)



Carburize-Economically

The A. G. F. Way

VERTICAL GAS CARBURIZER

A straight line is the shortest distance between two points

ROTARY GAS CARBURIZER

Likewise, the quickest, most economical way to carburize is to use gas.

When you carburize the A. G. F. Way with natural gas, propane or suitable city gas, it is quicker because the retort stays in the furnace and remains hot from one charge to the next. There are no heavy boxes and compound to be heated with each fresh charge. Thus, the heating up time is greatly reduced and thereafter, carburizing proceeds at the normal rate.

Gas Carburizing is most economical in Rotaries and Verticals for the same reasons, and also because of the small amount of labor that is required and many other inherent advantages.

New equipment in numerous cases has paid for itself in less than a year, has reduced carburizing costs by 2c per pound or more, etc.

If you are carburizing gears, crankshafts, bushings, piston pins, bearing parts or any one of a thousand other parts, investigate the possibilities of Gas Carburizing the A. G. F. Way.

These machines are also suitable for clean hardening, "Ni-Carbing", nitriding, normalizing and annealing. May we send you a circular telling more about them?

TAKE OUT A LONGER LEASE ON REFRACTORY LIFE

Use J-M Hellite, an air-setting, ready-mixed cement for bonding brick joints and washcoating refractory walls! Easily worked, it has high adherence . . . minimum shrinkage. Will not "bloat" on rapid heating. In short, it is the ideal cement for all service conditions up to 3000° F.

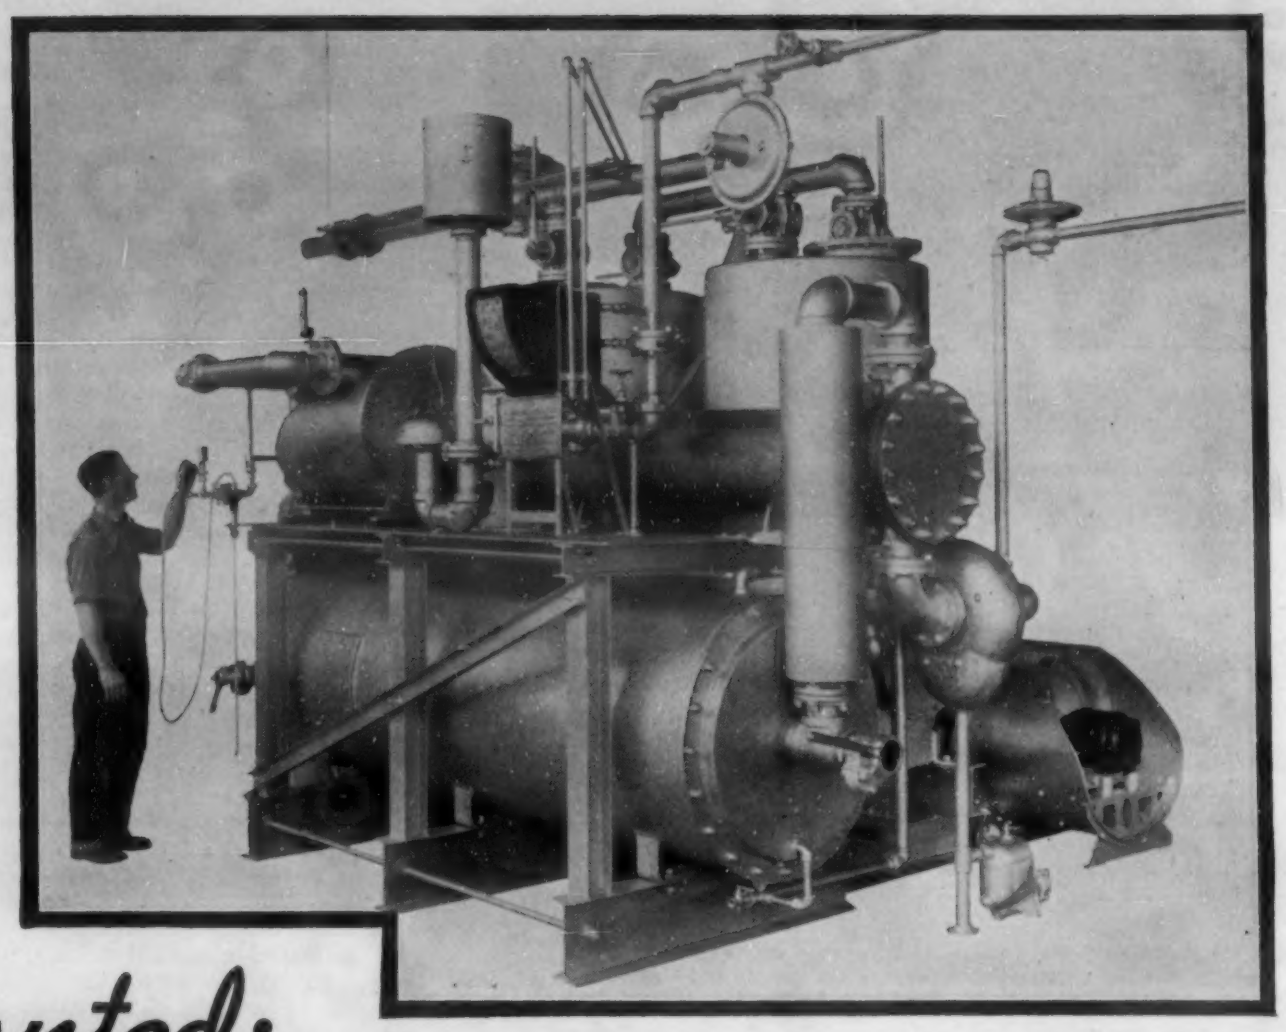
For complete data on Hellite and all other J-M Refractory Cements, ask for our engineering brochure DS-700. Johns-Manville, 22 E. 40th St., New York City.

JM Johns-Manville
REFRACTORY CEMENTS

Notes on Nitriding. V. O. HOMERBERG (Mass. Inst. Tech.) *Ind. Heating,* Vol. 5, Oct. 1938, pp. 917-920. Experiments have shown that nitriding increases the endurance range as determined by reversed bending. Fatigue failures do not begin at the surface but at the junction of the case and the core; the endurance of nitrided parts depends to a large degree on the characteristics of the core. Surface features, such as scratches, notches and threads, have a much smaller effect in nitrided than in unnitrided material. Work of other investigators is reviewed, and means for protecting parts not to be nitrided by plating with Sn or Ni or by painting, are discussed. Ha (5a)

Making Springs. *Steel,* Vol. 103, Sept. 19, 1938, pp. 66, 72. Practical. Describes specialized types of furnaces required in forming and heat treating coil springs. Bars are heated, prior to coiling, to 1650°-1750° F. in long, narrow furnaces. Heating time and amount of scale formed are kept at a minimum, and temperature is distributed uniformly by means of a large number of relatively small soft-flame type burners equipped with air-gas ratio control. Continuous type furnaces, equipped with automatic temperature and air-gas ratio control, heat the formed springs prior to oil quenching. Springs are drawn at 500°-1100° F. in a furnace equipped with a recirculating type of air heater. MS (5a)

The Tempering of Fe Containing Fe Oxide (Sur la Trempe du Fer Contenant de l'Oxydule de Fer) WITOLD BRONIEWSKI & STANILAS MAZGIS. *Compt. Rend.,* Vol. 207, Aug. 1, 1938, pp. 342-344. Original research. O in Armco Fe occurs as Fe_2O_3 at ordinary temperatures, but changes to FeO above 570° C. Because tempering allows part of the oxides to dissolve in the Fe, a study of the change in physical properties due to the presence of O was made after heating samples from 500° to 1450° C. The effect is not regular and must be related to the allotropic modification of the Fe dissolving the oxide, but only in very general fashion. Tempering increases the hardness, tensile strength and electrical resistance, and decreases the elongation and solution potential. FHC (5a)



New Furnaces. *Steel,* Vol. 103, July 18, 1938, pp. 42-43. Descriptive. Columbia Tool Steel Co., Chicago Heights, Ill., has installed 3 new gas-fired furnaces for heating ingots and billets for forging. They are of the box type, steel cased and insulated. They embody improvements in combustion-chamber design and in application of burners and controls, giving a flame of definite characteristics. Scale loss has been reduced from 6% to 2.1% of material used. MS (5a)

The Heat Treatment of Special Alloy Steels; The Most Common Processes of Heat Treatment—Noteworthy Points in Heat Treatment of Substitute Steels (Die Warmbehandlung der Edelstähle; die gebräuchlichsten Verfahren der Warmbehandlung—Beachtenswerte Punkte bei der Warmbehandlung der Austauschstähle) H. TREPPSCHUH. *Maschinenbau Betrieb,* Vol. 17, Sept. 1938, pp. 449-453. Review. *Structural steels:* Case hardening steels contain maximum 0.2% C, possibly with additions of Cr, Ni, V, Mo, Cr-Ni, or Cr-Mo. Carburizing temperature should not be too high nor the agent too strong. Failure to observe these precautions has caused difficulties where Cr-Mo steels are used instead of Cr-Ni, because Mo eagerly forms carbides; it produces too high a C concentration, resulting in carbide network, brittleness and pealing on subsequent machining. Special milder carburizing compounds were developed for these steels. The case on Cr-Mo steels is harder, so that a tempering operation at 160-180° C. in oil bath for 1-2 hrs. is necessary to insure ductility of the case and to improve machinability. The advantages of nitriding are: Low temperature (500°-550° C.) and relatively low internal stresses (cooling in air). Disadvantages are: Special alloy steels are needed and the time cycle is longer. Heat treatment at relatively high temp. of the special alloy steels containing 0.25-0.50% C with additions of Mn, Cr, Ni, Mo and V results in excellent physical properties. The hardness penetration is inferior when using Cr-Mo steels as compared with Cr-Ni steels, although the difficulties can be overcome by choosing the material according to the size of the pieces to be treated. For large pieces the addition of Ni is still recommended. Cr-Mo and Cr-Ni steels are equivalent as far as distortion is concerned. The former are highly wear-resistant and, after special heat treatment, quite machinable. *Tool and high-speed steels:* The W content of high-speed steels does not have to be as high as 18%. Steels with 13% W, 4% Cr, and 2.5% V, or 13% W, 4% Cr, and 4.5% V are in use, and the W content may be even as low as 6%. During heat treatment these steels must not be held at hardening temperature longer than absolutely necessary lest toughness be decreased. Simple shapes with short heating-up period can be hardened from 1230° to 1260° C., heavier and intricately shaped tools from 1200° to 1230° C. Drawing temperatures are 520°-540° C. W can successfully be replaced by Mo. A typical composition is: 2% W, 8% Mo, 1.2% V. The heat treatment is different in that heating above 800° C. involves the danger of decarburization, especially in oxidizing atmospheres. Salt bath or controlled-atmosphere furnaces are therefore used for hardening. Maintaining the hardening temperature of 1200°-1220° C. as closely as possible, and holding at heat as short a time as possible, are essential requirements. Drawing at 530°-550° C. produces secondary hardness, just as with regular high-speed steels. [Many of the above points pertain to substitute materials termed "exchange steels," recommended to reduce Germany's import of metals from abroad. It is claimed that most of them are at least equal to standard materials, sometimes with precautions or after special treatment. Restraint seems to be in order when generalizing the results.—R.P.S.] RPS (5a)

Improved Annealing Covers for Tin Plate. *Steel,* Vol. 103, Aug. 8, 1938, pp. 39, 56. Descriptive. New covers for annealing cold reduced strip steel in coils have 3 rows of horizontal, gas-fired, radiant tubes. 2 parallel rows of coils can now be heated instead of one. Each cover has a single exhaust fan which entrains gas for combustion and exhausts combustion products. Coils are placed on bases, and inner covers of light, mild steel sheets are placed over them, in sand seals in bases. Each coil base has a recirculating fan in center and is cored to admit protective atmosphere into inner cover. After all coils are covered, outer cover is placed in its sand seal, burners are lighted, and recirculating fans started. After coils reach annealing temperature, outer cover is removed and transferred to another loaded base. Fans continue in operation until coils have cooled. Mixture of blast-furnace and coke-oven gas containing 300 B.t.u./ft.^{3}, supplied at 20 oz. pressure, is burned. Results are increased tonnage capacity per cover, and faster and more uniform heating and cooling. MS (5a)

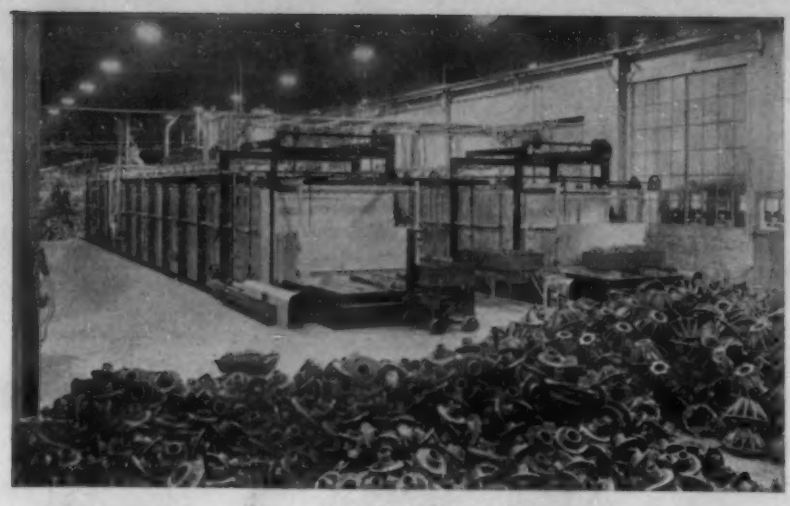
The Heat of Formation and Specific Heat of Chromium Nitride. SHUN-ICHI SATOH. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Sept. 1938, pp. 1001-1009. In English. Original research. The specific heat of Cr nitride had not previously been determined . For 3 temperature ranges up to 511° C. the following equations were established: for Cr_2N : $C = 0.1507 - 1.1654 \times 10^{-5}T + 1.2534 \times 10^{-7}T^2$; and for CrN : $C = 0.2096 - 2.328 \times 10^{-4}T + 3.939 \times 10^{-7}T^2$. The following heat of formations of chromium nitrides were determined: $2\,Cr + N = Cr_2N + 26{,}340$ cal., and $Cr + N = CrN + 28{,}260$ cal. EF (5a)

Economies Derived in Using Firebrick Soaking Pit Covers. *Steel,* Vol. 103, July 18, 1938, p. 66. Use of insulating fire-brick in soaking-pit covers results in considerably lighter cover structure; saving in power for lifting and handling; reduced damage to brickwork; less frequent repairs; longer service life; and appreciable fuel savings. MS (5a)

Kemp 8,000 C. F. H. Atmos-Gas Producer with twinned, activated alumina towers.

Wanted:

FUSSY CUSTOMERS!



We want to talk to the hair-splitters of the steel industry, men who can spot a blemish as far as they can see a stack of sheets . . because *we've got something* for them.

An imposing number of plants famous for rigid quality control are now using the Kemp Atmos-Gas Producer for bright annealing. But there are many more who will, once they have checked into the experience of present users and the three points of Kemp superiority:

1. Accurate proportioning of air and gas via the Kemp Industrial Carburetor.
2. Automatic continuous sampling by the Kemp Constant-Analysis Monitor which double checks and master-minds the Industrial Carburetor.
3. Complete dessication (to the equivalent of a —40F dew point) with 100 percent availability through *activated alumina dryers.*

You'll want to know more, *much more,* about these Atmos-Gas Producers. Write, wire or phone **The C. M. Kemp Mfg. Co. at 405 East Oliver Street, Baltimore, Md., or Oliver Building, Pittsburgh, Pa.**

KEMP of BALTIMORE

Saved 133 Hours

In Annealing Time
And Entirely Eliminated Scale

The above installation anneals malleable in about one-fifth the time required by the former method. In addition to the saving in annealing time these furnaces made possible quicker deliveries, produce more uniformly annealed castings, reduced fuel and labor costs, provided cleaner castings, improved working conditions and entirely eliminated scale.

This is one of the number of interesting installations we have made in prominent plants. We build furnaces for bright annealing, scale-free hardening, carburizing, copper brazing, nitriding, forging, billet heating and every other heat treating process.

Send for printed matter.

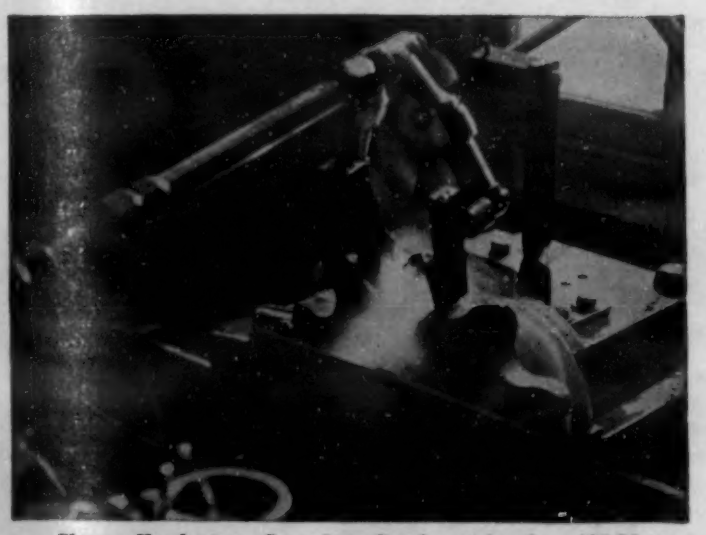
NEWARK, NEW JERSEY

Heat Treating Wire Machine Parts. J. B. NEALEY (Am. Gas Assoc.) *Heat Treating Forging*, Vol. 24, Sept. 1938, pp. 470-471. Description of furnaces used in plant of Sleeper & Hartley, Inc., Worcester, Mass. Carburizing is done in an oven-type furnace underfired with 10 gas burners divided between 2 sides and staggered, so that alternate streams of hot gases pass each other and flow up and across heating chamber above hearth. Temperatures up to 1800° F. are used in this furnace. C-steel gears, cams, etc., are heated in another oven-type furnace, with temperatures ranging from 1000° to 2000° F. A unique feature is that it contains no fire-brick except in hearth. Walls, top and bottom are of 9 in. of insulating refractory inclosed by a steel case. The hearth is underfired by a double set of gas burners, for high and low temperatures. 2 burner nozzles of different capacities, one concentric within the other, are in a single casting. Salt bath with atmospheric ring-type gas burner below pot is used for drawing and tempering work at 300-800° F. Parts requiring hard wearing surface and comparatively soft core are hardened in a cyanide pot that sits in a furnace consisting of 9 in. of insulating refractory within a steel shell. 4 tunnel-type gas burners, equally spaced on furnace wall both circumferentially and vertically, fire tangentially to inside of wall, without flame impingement on pot. Use of refractory insulation results in saving of gas to heat furnaces and to hold them at temperature. MS (5a)

Some Results Obtained with Chrome-magnesite Bricks in Open-hearth Steel Furnaces. A. E. DODD. *Trans. Ceram. Soc.*, Vol. 37, Aug. 1938, pp. 339-342. Original research. Laboratory tests with chrome-magnesite bricks showed remarkable spalling resistance and refractoriness under load. Two service tests were next tried. In the first, the gas ports and blocks of a 70-ton basic furnace were built of the bricks to be tested, set dry and separated by steel strips. After 20 weeks' working, it was observed that at a short distance from the exposed face, the chrome-magnesite had developed a reddish color, quite different from the brownish-purple of the unused bricks, and a crust of magnetic oxide of Fe had formed on the brick surface. In the second trial, parts of the air uptakes of a 200-ton tilting furnace were lined with the bricks. After a campaign of 22 weeks, the bricks had worn from an original thickness of 9 in. to a final thickness varying between 1½ in. and 3 in. This loss by flaking may be due to the formation of narrow zones behind the working face, and if these zones are due to the absorption and migration of slag and impurities, the flaking may be a physical spalling due to differences in the thermal expansion of the zones. GTM (5a)

Strip Annealing. J. B. BRUNOT, JR. (Penn. Ind. Engrs.) *Steel*, Vol. 103, Aug. 22, 1938, pp. 45-46. Descriptive. Several troubles encountered in annealing high-alloy strip steel, such as 28% Cr or 18% Cr-8% Ni, were overcome by use of a semi-muffle type continuous furnace, gas-fired with automatic fuel-air ratio. Pickling fumes are excluded by use of sealed-in burners using air drawn from a distance from pickle room and maintaining furnace at a positive internal pressure, or by locating pickling equipment in a separate room which retains fumes. Semi-muffle type permits rapid heat transfer to work and is less expensive in first-cost. Atmosphere is controlled by carrying furnace at positive pressure and maintaining constant fuel-air ratio at all operating rates. Exhaust flues in roof are used only during light-up periods. When furnace is operating, combustion products are exhausted through door openings. Rolls built of specially prepared refractory material over a solid steel shaft are provided at inlet and outlet of furnace. Full-muffle furnace, in which strip passes through furnace in an atmosphere of air, has also been used successfully for annealing alloy strip. In this case, burners are set for most economical rate of combustion. MS (5a)



New Carburizing Methods for Iron and Steel. (Neue Zementierverfahren für Eisen und Stahl) KALPERS. *Tech. Blätter*. Vol. 28, July 24, 1938, pp. 434-435. Description of several new methods: Application of special carburizing pastes; addition of asbestos to the liquid baths to avoid decarburization; improvement of cyanide bath by additions of SiO_2, boric acid or SnO_2 to bind the alkalis formed by decomposition of the cyanides; carburizing bath applying neutral salts; use of dispersed C and caustic alkalis, making possible short carburizing time; and baths with carbides of the alkaline earths as carburizers. GN (5a)

Atmosphere Control in Annealing Malleable Iron. E. G. DE CORIOLIS & R. J. COWAN. *Ind. Heating*, Vol. 5, Sept. 1938, pp. 786-788, 834. Descriptive. Methods for preventing or retarding decarburization, and the proper use of atmospheres are discussed. The main principle is to secure a correct balance between CO and CO_2 in the malleableizing atmosphere. This is obtained by burning the fuel gas, manufactured or natural, in an enclosed chamber with a controlled proportion of air which can be varied to give as high as 12% CO_2 and no CO, or as low as 5% CO_2 and 10% CO. Continuous and intermittent type furnaces are described; the total annealing time is about 36 hr. in the former, 48 hr. in the latter type. Ha (5a)

Flame Hardening the Roller Pad, with the AIRCO Torch and Tip mounted on the motor driven AIRCO Radiagraph.

FLAME HARDENING *proves its worth on Thew Power Shovels*

Flame Hardening Sprocket Teeth with the AIRCO Adjustable Yoke and Gear Hardening Tips.

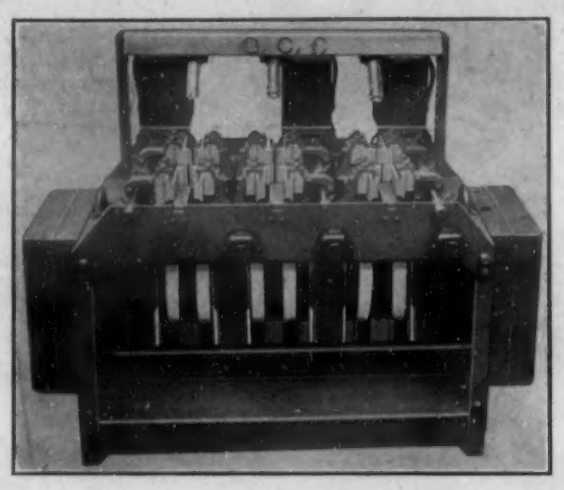
The outstanding ability of Thew Shovels to stand up on jobs like this is pretty strong evidence of the hardening results produced by flame hardening.

Power shovel parts are subjected to terrific strains. Hardening them to take these strains with a minimum amount of wear presents many problems. For example, warping is difficult to avoid when ordinary hardening methods are used. Oxyacetylene Flame Hardening proved to be the answer to these problems for the Thew Shovel Company.

In 1936, Thew engineers decided to try this process on one of the parts presenting the greatest difficulty. With AIRCO Engineers assisting, experimental castings were flame hardened. Then they were subjected to the most searching tests and inspections, both in the laboratory and in actual service. Accurate cost records were kept.

Results: distortion, and the extra machining it made necessary, were eliminated; savings were effected on material as well as labor; degree of hardness and depth of penetration proved to be readily controlled and accurately duplicated.

Today, 27 individual parts of Thew power shovels are flame hardened on a production basis. They include spur and bevel gears, brackets, brake bands, spindles, roller pads, clutch jaws, etc.



OXYACETYLENE FLAME HARDENING may well be the answer to your hardening problems. AIRCO, pioneer in developing the process, will be glad to help you investigate. As a first step, write for a copy of the FLAME HARDENING BULLETIN.

1 **A Description of the Age Hardening Process as Applied to Castings.** L. W. KEMPF (Aluminum Co. of America) *Trans. Am. Foundrymen's Assoc.*, Vol. 46, Sept. 1938, pp. 19-40. Review. The possibilities of precipitation hardening as an aid in widening the field of application of castings are discussed. The fundamentals of the process are first considered, using simple illustrations of structural and property changes in pure binary alloys. By reheating the casting to a temperature just below the eutectic temperature for a sufficiently long period, it is possible to attain a saturated solid solution. This equilibrium concentration may be maintained by rapid cooling to room temperature. Because this is a supersaturated structure, there will be a tendency for the alloy constituent or compound to precipitate. The tendency for the precipitation to occur will increase rapidly with increase in temperature. Considerable commercial application has been made of precipitation hardening, particularly in non-ferrous fields. The change in solubility of Cu in Al is the basis for a casting alloy containing about 4% Cu. Tensile strength in the as-cast condition of 22,000 lbs./in.^{2} may be raised to 40,000 lbs./in.^{2} by heat treatment. The solid solubility of Mg in Al varies from about 15% at eutectic temperature to less than 3% at room temperature. Al alloys containing more than about 6% Mg are quite amenable to heat treatment. Other alloys, such as Cu-Cr with 0.5% Cr, Cu-Si with over 3% Si, Cu-Be with 1-3% Be, Al-bronze and Cu-cast irons are mentioned. CEJ (5b)

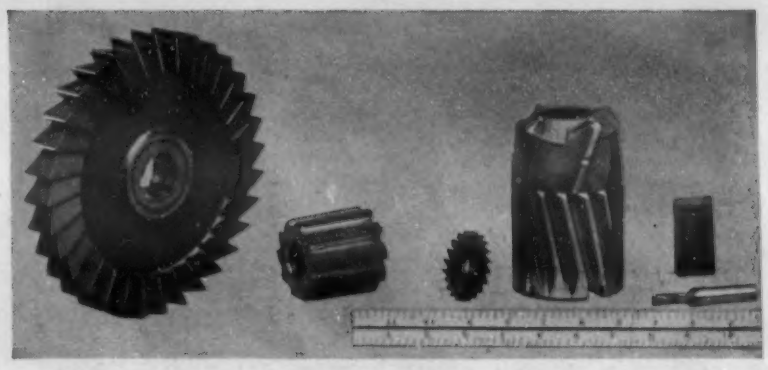
4 **Change of Elastic Limit of an Aluminum Wire by Annealing.** MIYABI SUGIHARA. *Mem. Coll. of Sci., Kyoto Imperial University, Series A,* Vol. 21, Sept. 1938, pp. 145-162. Research. A cold-worked Al wire was heated in an electric furnace, then cooled suddenly to room temperature, and the change of elastic limit measured. The elastic limit decreases with the rise of annealing temperature and annealing time. The plastic elongation of an annealed Al wire and its elastic limit were measured repeatedly after a lapse of certain time intervals. The elastic property is recovered, and, after the lapse of a certain time, the elastic limit becomes somewhat larger than initially. A cold-worked Al wire was annealed, stretched beyond its elastic limit, and annealed again for various time periods at various temperatures. When the second annealing temperature is comparatively low, the elastic limit of the wire increases at the beginning of the annealing period, and in some cases reaches a maximum. This increase of the elastic limit by weak annealing was ascribed to the recovery of the spots of weak inter-atomic cohesion, formed by the previous plastic deformation. HN (5b)

6 **Light Metal Manufacture. Rotary Hearth Furnaces for Continuous Production.** ROBERT HAMACHER. *Metal Ind., London,* Vol. 53, Oct. 7, 1938, pp. 345-346. Descriptive. Rotary hearth furnaces, employing forced air circulation for the heat treatment of light metal pressings and pistons, are described. Heating in conventional furnaces fails to satisfy present requirements, for the temperatures required are usually below the temperature of radiation of the heating elements used in the construction of standard electric furnaces. For temperatures under 500° C. heat transfer by radiation to the charge is too low to attain an economically short heating period. Such drawbacks may be definitely avoided by the employment of artificial air circulation, with shortening of the heating-up time. 58 min. were required to heat a piece to 460° C. with the ordinary furnace, but only 23 min. with forced air circulation. A description of a special rotary hearth furnace for heating cylindrical pressed parts is given. RWB (5b)

8 **The Heat Treatment of Magnesium Alloys.** L. G. DAY & H. G. HARRINGTON. *Light Metals,* Vol. 1, Sept. 1938, p. 269. Review. Mg alloys containing Al and Zn as the chief alloying constituents are subject to precipitation hardening. Although the tensile properties are improved by heat treatment, it is doubtful if the fatigue resistance is improved. Mg alloys for forging and pressing are not normally age-hardenable, since the alloying constituents in amounts requisite for age hardening do not allow much forming. Special atmospheres for heat-treating Mg alloys are necessary. Certain salt baths are used, but it is usually more convenient to use electric furnaces, or gas-fired furnaces with controlled atmospheres. Unlike Al castings, Mg castings do not require quenching in water and are usually relatively free from distortion and internal stress. AUS (5b)

10 **New "Z" Nickel May Be Heat Treated.** *Iron Age,* Vol. 142, Sept. 15, 1938, pp. 39, 49. Describes the application of heat treating to 98% Ni alloy. The "Z" Ni has a strength 2½-4 times that of ordinary structural C steel. It may be heat-treated after fabrication with little if any distortion at temperatures of from 800° to 930° F. for 6-16 hrs. It may be used for hand tools, wire brushes, spring clamps, etc. It is produced commercially as hot or cold rolled strip in a wide range of sizes. VSP (5b)

There is a BEST way to harden tool steels—and cut your tool and die cost at the same time!



Use "Certain Curtain" furnaces proven by 11 years success the world's established leader!

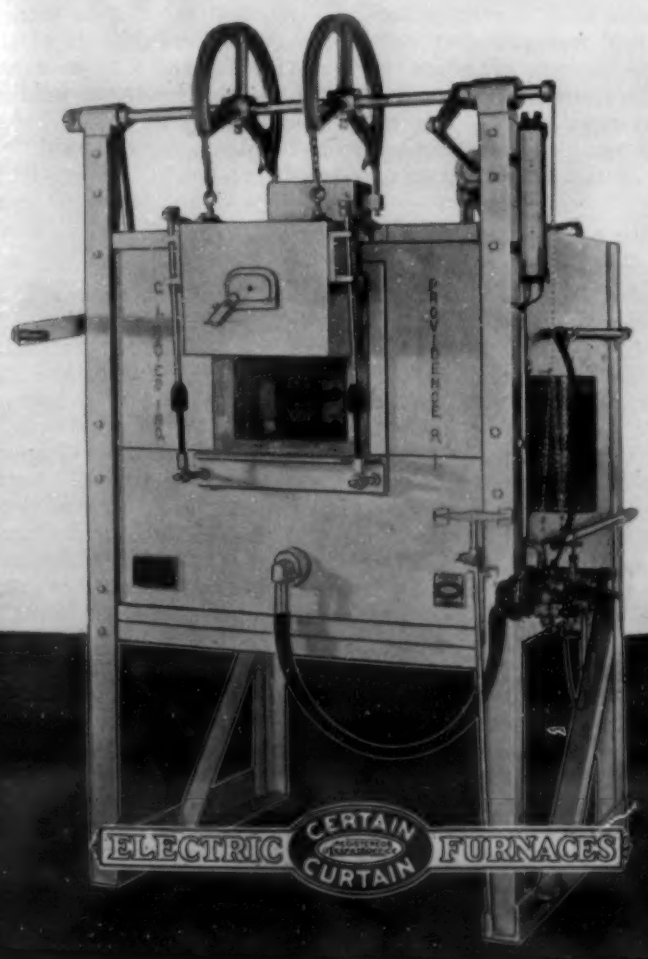
In the late 1920's users of high speed steels found that the new "Certain Curtain" furnaces virtually eliminated the difficulties of hardening tool steels, especially the high speed types. The patented control of furnace atmosphere produced definite results not previously obtainable, such as —

1. Protection of surface from attacks producing scaling or decarburization.
2. Control of grain structure under extended heating time.
3. Minimization of distortion, shrinkage and other size changes.

The cash value of "Certain Curtain" hardening was immediately demonstrated. The tools and dies cost much less to produce, yet had considerably greater working life.

In nearly 900 furnaces installed since their original outstanding success, Hayes furnaces have maintained an unbroken record of lower cost for better tools. Against the background of an almost endless variety of competing equipment, "Certain Curtain" is the only established and proven method that has stood the test of time in hundreds of plants, on many types of tool steels, under widely varying conditions.

From Tiny Taps To 50 lb. Hobs "Certain Curtain" Means Certain Success



One of the major effects of "Certain Curtain" control has been to eliminate the guesswork and compromise that formerly caused spoilage, or caused inferior working life due to fear of spoilage. Complete control of atmosphere protects the most delicate points and edges even when held extra long at the critical.

Famous makers of Custom Tools prefer it

Such well known tool firms as Cleveland Cutter and Reamer, Gorham Tool, Murchey Machine Tool, Michigan Tool, etc., find "Certain Curtain" invaluable because it protects them against spoilage and re-makes on special custom tools. In a month one firm hardened 2,000 hobs valued at $55.00 each without a single loss.

Users Report Amazing Savings

"Savings $521 per month" —— "Eliminated 11% spoilage on taps." —— "Saved cost of pair of furnaces in 5 months working 16 hrs. daily." —— "This daily $8 saving has paid for the furnaces in well under a year. Savings in the grinding room alone are $291 per month." —— "Savings far greater than anticipated."

Furnace shown at left is standard type HG for hardening high speed steels. Also made in vertical and extra large die sizes. Other "Certain Curtain" furnaces are for pre-heating high speed steel, hardening alloy, stainless and carbon steels, including standard, vertical, conveyor and special designs.

E. V. DAVID, SECTION EDITOR

Effect of Excess of Oxygen and Acetylene in the Welding Flame on the Mechanical Properties of Autogenous Seams (Einfluss des Sauerstoff-und Azetylenüberschusses in der Schweissflamme auf die Festigkeitseigenschaften von Autogennähten) H. HOLLER. *Autogene Metallbearbeit.*, Vol. 31, Oct. 1, 1938, pp. 313-316. Original research. With increasing ratio O_2:C_2H_2, the Brinell hardness decreases because of the increased O_2 absorption; the optimum of notch-toughness occurs at the ratio 1:1. Notch-toughness decreases with excess of either of the gases in the flame. The maximum tensile strength occurs between 1:1 and 1.1:1. Elongation and reduction of area also become very small with increased O_2 and C_2H_2 excess. Welding with excess of O_2 is not very difficult. Excess of C_2H_2 gives rise to difficulties; satisfactory joints can be made only up to a mixture of O_2:H_2C_2 of 0.9:1, a greater excess resulting in porous joints. Best nozzle shapes are briefly discussed. Ha (6)

X-ray Study of Defects in Metal-arc-welded Parts of Mild Steel and their Effect on the Mechanical Properties. HARUMASA EKOGANEI & HAZIME NAKAMURA. *Trans. Soc. Mech. Eng., Japan*, Vol. 4, May 1938, pp. 172-177. In Japanese. English abstract p. S31. Original research. The general effects of defects (observed by X-ray photographs) on the physical properties are studied. The results are summarized as follows: *Deposited metal*. Specific gravity decreases as size and number of blow holes increases. Quantitative relation between them was not recognized. Electric resistance and permeability may have some bearing on the number of blow holes appearing in the X-radiograph, although this was not successfully proved. Tensile strength is always over 61,500 lbs./in.^{2} regardless of blow holes. Elongation and reduction of area vary markedly, depending on the amount of blow holes. Impact values vary according to number and distribution of blow holes as well as with microstructure. *Welded Part.* Electric resistance and permeability vary only slightly with the number of blow holes. Tensile strength does not vary, since the welded part is stronger than the parent metal. Free bending values vary according to the number of blow holes. If undercuts exist, a marked change takes place. However, the cast structure at the surface decreases the free-bending value. Thus a consideration of the microstructure is necessary. Impact value of the welded part varies according to number and distribution of blow holes and microstructure. The effects on fatigue limit of welded parts are still being studied. Results obtained so far show that the microstructure and distribution of blow holes has some effect on fatigue. EF (6a)

Flame-cutting of Cast Iron. C. H. S. TUPHOLME. *Foundry Trade J.*, Vol. 59, Sept. 15, 1938, pp. 203, 204. Practical. Cast Fe cutting requires a somewhat different technique from that used in cutting ordinary steel, although the equipment is substantially the same. The difference lies mainly in the manipulation of the blowpipe, the flame adjustment, and in the handling of the work in general. Those who already have oxy-acetylene cutting equipment, including a good general-duty cutting blowpipe and an O regulator of sufficient capacity for the pressure necessary, require no other special equipment for the average run of work. O supply, type of flame, O lance cutting, use of Al, etc., are discussed. If a tough adherent layer of slag forms on the metal in the kerf, and prevents further oxidation, the use of Al is recommended. Usually no more than 2 handfuls are necessary even for a large mass of Fe. Al acts as a flux to make the slag more fluid, and thus enables the cutting to continue. The oxidation of Al also supplies additional heat. Crushed Si or ferro-silicon may sometimes be used instead of Al as a fluxing material. AIK (6a)

Welding of Cast Iron (Beitrag zur Gusseisenschweissung) W. GEORGE. *Autogene Metallbearbeit.*, Vol. 31, Oct. 15, 1938, pp. 329-333. Five methods are discussed: Autogenous semi-hot welding, electric semi-hot welding, electric cold-welding, autogenous hot-welding, electric hot-welding. Semi-hot welding is called the welding without general preheating of the piece, and is used preferably for small pieces that heat sufficiently under the torch or electric arc. Electric cold-welding is advantageously used for repairing small defects in large pieces. A number of examples of all types are described. Ha (6a)

Strength Tests on Welded Corner Joints (Festigkeitsversuche an geschweissten Eckverbindungen) TASCHINGER. *Organ Fortschr. Eisenbahnw.*, Vol. 93, July 1, 1938, pp. 241-248. Original research. The object of the investigation was to study by tensile, compression and torsion tests the performance of welded corner joints made of rolled profiles and welded sheets. All samples were made from the German structural steel ST 37 (37 kg./cm.^{2} tensile strength). Welded sheets proved to be far superior to rolled profiles in tension. Cracks appear at considerably higher loads and at a safe distance from the welds. With rolled profiles, the cracks occur at relatively low loads in the welds in this static test. Under dynamic loads, this shortcoming will be much accentuated. In compression welded-sheets are also superior to rolled profiles, though less than in tension. No general conclusions from the torsional tests are warranted. The open profile samples are not suitable for this method of testing. Furthermore, there is no analogy between the clamping in the testing machine and actual service conditions. EF (6a)

Welding of Nickel-free Acid-resisting Steels (Das Schweissen der nickelfreien säurebeständigen Stähle) H. HOUGARDY. *Maschinenbau Betrieb*, Vol. 17, Aug. 1938, pp. 411-412. Practical. The ferritic acid-resisting steels, containing 16-18% Cr with or without Mo (1.8%) and widely used for chemical apparatus, show considerable grain growth and brittleness on heating above 1000° C. Grain growth depends not only upon the temperature itself but also upon the length of time during which heat is applied. Therefore, electric arc welding is better than autogenous welding for these steels. The ductility can be increased by annealing between 700° and 800° C. The addition of so-called carbide-forming elements, such as Ti, Ta and Cb, in a range of 0.5-2% hampers grain growth and thereby improves welding conditions considerably, and makes annealing unnecessary. As welding rod material, austenitic material of the same chemical characteristics as the ferritic matrix is recommended. RPS (6a)

6b. Non-Ferrous

Methods of Joining Copper Alloy Products, Part VII. Sheets. I. T. HOOK. *Metal Ind., N. Y.*, Vol. 36, Aug. 1938, pp. 382-384; Sept. 1938, pp. 427-429; Oct. 1938, pp. 472-474. Practical. Oxy-acetylene fusion welding of Cu, brass, "Everdur Silicon Bronze" and other alloys is often done without the use of a back-up bar. Corner welds can be made using a Cu or steel backer if it is protected with asbestos. $ZnCl_2$ flux is used for soft solder; resin or tallow are used where Cu or brass parts are tinned. Borax and boracic acid are used for brazing fluxes. NaCl is added to such fluxes for Cu welding; sodium and potassium fluorides are added for Ag soldering and welding Cu-Si alloys. Soft solders are used for metal-to-metal bonding as in electrical connections and as a sealing agent for riveted, lock-seamed or spot-welded joints. Pure grade Cu containing 0.05% Ag may be soft soldered without loss of its cold work strength and stiffness. Brazing and bronze welding are used when the strength of the joint is of paramount importance. Requirements in a Cu alloy weld are: (1) Strength, soundness and ductility; (2) comparable corrosion resistance, welded seam to sheet, and (3) color match. Welding technique for electrolytic Cu, tough pitch Cu, arsenical Cu, lake Cu, O_2-bearing Cu, electrical Cu, deoxidized Cu, commercial bronze, red brass 85, red brass 80, spring brass, yellow brass, Muntz metal, silicon red brass 1029, "Everdur Silicon Bronze," nickel silver, Ambrac, super nickel silver, phosphor bronzes, Ambraloy 901, and Be-Cu are discussed. For Part VI, see also *Metals and Alloys*, Vol. 9, Oct. 1938, p. MA 608R/6. CBJ (6b)

7a. Electrolytic Methods

The Adherence of Thick Silver Plate on Steel. F. C. MATHERS & L. I. GILBERTSON (Indiana Univ.) *Trans. Electrochem. Soc.*, Vol. 74, 1938, Preprint No. 30, 15 pp. Original research. The adherence and hardness of Ag deposits up to 0.05 in. thick were studied for the purpose of applying them to the production of bearings. The adherence of the deposit was determined qualitatively by noting whether the Ag separated from the steel when the specimen was bent back and forth until it broke. The thickness of the deposit affected the apparent adhesion of Ag, for some adherent thin coatings showed lower adhesion when their thickness was increased by further plating. Annealing of the deposits at 1000° F. for an hour increased the adhesion of the Ag. Brush plating gave a lower degree of adherence than the usual plating methods. The steel was prepared for plating by the usual cleaning procedures. followed by an acid dip consisting of 15 sec. immersion in 10% HCl, at 90° C. Better adherence was obtained on steel containing over 0.1% C, if an anodic treatment in 80% H_2SO_4 or a cathodic treatment in 10% HCl were used instead of the dip. The acid treatment was necessary for good adherence; it probably removed the oxide film and roughened the surface. Good adherence could not be obtained without a strike. Either a Cu or a Ag strike could be used. The cathode must be connected to the current before being immersed in the strike, and the current density used must be sufficient to produce vigorous gassing. The composition of the strike was not critical, but for any strike the current density and time must be so chosen that the specimen is completely covered with a Ag deposit that must not be spongy. A satisfactory strike is 1.9 g./l. AgCN, 17.9 g./l. KCN, 3.2 g./l. K_2CO_3, 6-20 amp./dm.^{2} c.d., time—1-5 sec. Instead of using a strike, the steel could be immersed in a 2% gelatin solution and then plated. The results compared favorably with those obtained with the Ag strike. The Ag plating bath had the following composition: 26.3 g./l. AgCN, 46 g./l. KCN, 37.5 g./l. K_2CO_3, 13 g./l. free cyanide. Current density was 0.4 amp./dm.^{2}. A bath in which the K_2CO_3 was replaced by $NaClO_4$ was tried, but it gave a bright, brittle deposit. AB (7a)

3

The Electrodeposition of Chromium from Trivalent Salt Solutions. W. H. WADE & L. F. YNTEMA (St. Louis Univ.) *Trans. Electrochem. Soc.*, Vol. 74, 1938, Preprint No. 26, 7 pp. Original research. Cr was electrodeposited from a bath 0.5 M. in chromium sulphate and 2-4 M. in ammonium sulphate. Operating conditions were: Current density, 12.5 amp./dm.^{2}; temperature, 35° C.; pH, 2. The current efficiency was 10-15%. The deposits were crystalline and inferior in quality to those obtained from the chromic acid bath. The addition of 0.1 mole./l. of citric acid or ammonium oxalate improved the deposit but considerably lowered the current efficiency. These compounds form complexes with the Cr salt from which chromic hydroxide does not precipitate until the pH exceeds 6. AB (7a)

4

Determination of Porosity and Mechanical Damage of Protective Coatings on Light Metals by Anodic Precipitation of Organic Dyes (Bestimmung von Poren und mechanischen Verletzungen in Schutzüberzugen auf Leichtmetallen durch anodische Abscheidung organischer Farbkorper) V. DUFFEK. *Z. Metallkunde*, Vol. 30, Aug. 1938, pp. 265-267. Experimental. The anodic precipitation of a dye was the most satisfactory method found for producing a rapid and permanent indication of coating imperfections. The test is successful with oxide, metallic and nonmetallic coatings on Al. An alkaline solution of alkali salts of azo or sulfonated aromatic dyes was most generally useful. GD (7a)

5

New Method of Plating on Aluminum. WILLIAM J. TRAVERS. *Metal Ind., N. Y.*, Vol. 36, Oct. 1938, pp. 475-477. Descriptive. The Al object is first given a high polish and degreased. It is then given an anodic coating, and immersed in a solution that has a solvent action on the film, for a pre-determined time. Ni is most satisfactory for an initial deposit; other metals may be plated on the Ni deposit. Bright Ni may be used if desired. CBJ (7a)

6

Technical Control of Electroplating Processes. S. C. TAORMINA. *Metal Ind., N. Y.*, Vol. 36, July 1938, pp. 336-338; Aug. 1938, pp. 374-376. Review. The effective control of electroplating processes begins with the design and layout of the plating room. The control factors discussed are: Power and its proper use; instruments for electrical control; number and size of plating tanks; solutions and proper standards; chemical analysis; equipment required and interpretation of results. Cathode efficiencies vary with current density; therefore, if a specified thickness of plate must be obtained, and the current densities are not high enough, the chances are that in most cases the cathode efficiencies are overestimated. Current for barrel plating is best estimated on the basis of pounds of material, as only a small part of the surface to be plated in a barrel is being plated at a given instant; the current density on that surface is very high. The size of the tank is determined by the shape and amount of work to be handled. A tank capacity of about 1 gal./amp. to be used has been found in practice to be adequate for most baths. Ni solutions are not critically affected by temperature; the most important factor is pH. In barrel plating, dragout is high and daily adjustments are usually required. Cyanide baths offer considerably more difficulty in their control. Cyanide Cu for striking is used hot at high current densities; small tanks are used, and it is important to check the free cyanide frequently. Metal and carbonates should be analyzed about once a week. Cold cyanide Cu plating baths have high cathode efficiency and the Cu content should be held high. Hot Cu cyanide plating baths require careful temperature control. The chief difficulty with acid Cu baths is the introduction of Fe in the bath, which causes rough, dark and hard-to-buff deposits. Streaky deposits are caused by operating these baths at 50° F. and lower. Ag solutions are most easily controlled. With sufficient anode surface, hardly any silver-cyanide additions are required. On the other hand, Ag strike baths require close control. Gold cyanide is not a very critical bath but because of its high cost should be rigidly controlled. RWB + CBJ (7a)

7

Specification Plating. Methods of Determining Quality. N. HALL. *Metal Ind., London*, Vol. 53, Aug. 19, 1938, pp. 183-185. Description of testing methods. Plating to specification was introduced by the automotive industry. Sales propaganda claiming 3 or 4 deposits often impresses the average buyer more than actual thickness figures, but this method of meeting plating to specifications only evades the issue, because it neither improves nor maintains quality of the finish. The old methods of determining thickness involved stripping the deposit. The most serious difficulty, the accurate measurement of the area of irregular objects, could not be overcome without the expenditure of considerable time and effort. Of the newer methods Mesle's Chord method of measuring thickness is probably the best suited for use in the average shop. The method is not as accurate as the microscopic but is sufficiently so for all practical operations where the thickness is about 0.0002 in. It involves grinding through the deposit, and from the width of the spot where the base metal is exposed, and the known radius of the curved surface or of the cutting wheel, the thickness can be calculated. For deposits of Cd and Zn, the Hull-Strausser dropping method is very suitable and has been widely adopted for this purpose. This method has been modified to use a jet in order to corrode the more resistant metals like Ni and Cu, and is called the B.N.F. Jet Test. Magnetic testing devices are available but require standardization. Generally the drop and chord tests are recommended for small plants. When plating is done to an intelligent specification, it will be raised from the present uneconomic plane to a technically high-grade industry. RWB (7a)

8

9

Technical Control of Electroplating Processes. S. C. TAORMINA. *Metal Ind., N. Y.*, Vol. 36, July 1938, pp. 336-338; Aug. 1938, pp. 374-376. Practical. Control factors in electroplating processes are: (1) Power and its proper use, (2) instruments for electrical control, (3) plating tanks, number and size, (4) solutions and the proper standards and (5) chemical analysis, equipment required and interpretation of results. General control measures for Cu cyanide baths, brass and bronze, Ni, Cd, Ag or Au solutions are discussed. CBJ (7a)

10

The Electrodeposition of Silver Alloys from Aqueous Solutions. FRANK C. MATHERS & AARON D. JOHNSON (Indiana Univ.) *Trans. Electrochem. Soc.*, Vol. 74, 1938, Preprint No. 27, 22 p. Original research. Binary Ag alloys containing Cu, Co, Ni, Zn, Cd, Fe or Pb were electrodeposited. Observations were made of the physical properties and the adherence of the deposits. Their resistance to tarnish was determined by immersion in H_2S water containing H_2O_2. Cu-Ag alloys containing 2-60% Cu were obtained from a bath consisting of Cu and Ag nitrates and 80 g./l. of thiourea. The deposits were smooth and soft, but only moderately adherent. Ni-Ag alloys containing up to 74% Ni were deposited from a bath containing Ag and Ni nitrates and 100 g./l. of NaCNS. Deposits that contained 5% Ni were smooth and hard, but not brittle. Ni-Ag alloys were also deposited from a bath consisting of Ag and Cu nitrates, 150 g./l. of $NaNO_3$ and 40 g./l. of tartaric acid. The maximum Ni in the deposit was 3.6%, and the deposit was hard and brittle. Fe-Ag alloys containing 1% or less of Fe were deposited from a bath consisting of the metal nitrates and 80-150 g./l. of NaCNS. These alloys were more resistant to tarnish and to acids than the other binary alloys produced. A thiosulphate bath was also used, but was found to be too difficult to control. Soft, ductile Cd-Ag alloys containing up to 30% Cd were obtained from a NaCNS bath. Deposits from a thiourea bath were gray and spongy. Smooth, adherent Zn-Ag alloys, containing a maximum of 3.8% Zn, were deposited from a bath consisting of Ag, Zn and NH_4 nitrates. A thiocyanate bath gave unsatisfactory deposits of a Co-Ag alloy, and the bath decomposed during operation. Co-Ag alloys, containing 0.5% Co, were deposited from a thiourea bath. The deposits were white, smooth and harder than Ag, but not brittle. Pb-Ag deposits plated from a fluosilicate bath were unsatisfactory. Good deposits were plated from an acid tartrate bath, but they contained a maximum of only 0.5% Pb. Best results were obtained with a bath consisting of potassium plumbite and $KAg(CN)_2$. The deposits contained up to 70% Pb and were softer than Ag plated from a cyanide bath. The Co-Ag and Pb-Ag alloys tarnished more readily than pure Ag. AB (7a)

Electrolytic Deposition of Indium and Silver-indium Alloys (Die galvanische Abscheidung von Indium und Silber-Indium-Legierungen) E. RAUB. *Mitt. Forsch. Inst. Probieramt Edelmetalle, Schwäb. Gmünd*, Vol. 12, Sept. 1938, pp. 55-59. Original research. (For previous work, see *Metals and Alloys*, Vol. 8, Nov. 1937, p. MA 692R/6). The purpose of the investigation was to determine whether In-plating can prevent tarnishing of Ag, which alloying of In with Ag fails to do. Plating with In and Ag-In does not produce tarnish-proof layers; the deposits from cyanide, cyanide-free, chloride and sulphate solutions are sometimes very dull, and no really bright deposits could be obtained; polishing removes too much metal, or In is very soft. A superficial Ag-In alloy was obtained by diffusion in H of In-coated Ag sheets; this layer was hard and tarnish-proof; it was dull, however, even in the polished condition and cannot be used for practical applications. Ha (7a)

Bright Nickel Plating. *Steel*, Vol. 103, Aug. 29, 1938, pp. 50-52. Industrial note on process developed by Seymour Mfg. Co., Seymour, Conn., and its application to manufacture of flat-irons. Uses purified and filtered standard Watt's bath containing certain addition agents [composition not stated]. Advantages claimed: Production of soft, ductile, brilliant Ni plate; freedom from pitting; ease of operation; good throwing power; bright plate at all thicknesses; and ability to Cr plate without activation or color buffing. Chief advantage is elimination of finishing operations before Cr plating. Base metal, which may be ferrous or non-ferrous, must have a suitable high finish to be bright Ni-plated directly by the process. Before adding ingredients for process, Cu, Fe, etc. are removed from Watt's solution. It is then heated to at least 150° F. and enough lime (at least 5 lbs./100 gal. solution) is added to bring pH above 6.5 quinhydrone. After 1 hr. at 150° F., 32 oz. of 100-volume H_2O_2 is added per 100 gal. bath and stirred. After settling over night, solution is filtered into plating tank. Temperature is adjusted to 110° F. and pH to 2.8 quinhydrone. Adjustment of latter is made with H_2SO_4 or $NiCO_3$. MS (7a)

Radiator Grilles. *Steel*, Vol. 103, Sept. 12, 1938, pp. 58-60. Description of commercial installation for automatic Cr-plating at Cadillac Motor Car Div., General Motors Corp. All parts, regardless of size or shape, are routed through the same Cr-plating equipment, using a constant current-density. Parts, after polishing, buffing and degreasing, are Cu-plated in a $Cu(CN)_2$ solution of so-called low-Rochelle type, containing 2 oz. salts per gal. Positive contact between racks and bus bar running along side of tank is insured by playing H_2O stream continually on bus at the spot where rack first makes contact. Parts are then washed and bright Ni-plated. Both Cu and Ni solutions are continually filtered and passed through heat exchangers to maintain proper temperature. An important factor in efficient operation of Cu and Cr tanks is careful balancing of loads. Special types of racks were constructed for Cr-plating. Brass wire "antenna" around the outside of rack is connected to cathode side to pick up excess current and prevent burning of outside pieces. Auxiliary Ni anodes near the center of each rack are energized by a bipolar generator operated with plating machine, and give off enough additional current to balance rate of deposition at center with rate at outside. Parts are cleaned electrolytically, rinsed, dipped in 5% H_2SO_4, rinsed, and Cr plated in CrO_3. Temperature of bath is held at 120° F. ±2° by a controlling pyrometer which pumps solution through either a heat exchanger or H_2O cooler. A generator supplies 3,000 amps. at 14 volts to the work the moment it enters tank, and continuing for 20 sec. Then, by means of breakers in anode and cathode rails, a second generator is cut in to supply 6,000 amps. at 5 volts. Auxiliary anodes are supplied with 3,000 amps. at 6.5 volts. Initial high voltage and lower current produce an instantaneous Cr layer over all exposed surfaces. Then, by easing off voltage and stepping up current, the deposit is built up gradually to required thickness. Dragout is reclaimed by dipping work in an adjoining tank, resulting in considerable saving of CrO_3. Plated parts are given several rinses. At usual production speed, circuit through the machine requires 18 min. MS (7a)

Corrosion of Silver Anodes in Potassium Silver Cyanide Plating Solution. A. E. THURBER, DANIEL GRAY & R. H. SHOLTZ (Oneida Ltd. Labs.) *Trans. Electrochem. Soc.*, Vol. 74, 1938, Preprint No. 20, 15 pp. Original research. Good Ag anodes should corrode evenly down to thin scrap and should not produce loose particles or sludge that may cause rough deposits. The Ag anodes used in the investigation were in most cases over 99.95% pure Ag, the impurities being mainly Cu, Fe, Pb, Mn and Bi. Pb and Bi in anodes cause uneven corrosion and form a sludge. Small quantities of Cu (a few hundredths %) and Mn (about 0.001%) are not harmful. Anodes having a fine grain size corrode more smoothly than others. The black sludge from some anodes was analyzed and found to contain C and other organic material, Pb, Fe, Bi, Mn and sometimes Sb. AB (7a)

7b. Non-Electrolytic Methods

Brass Spraying with an Electrically Operated Spray-Gun. Y. HOSINO & T. TAKEI. *Nippon Kinzoku Gakukai-Si*, Vol. 2, July 1938, pp. 318-324. In Japanese. Original research. Cu content of the coating increases with increasing arc-voltage and air blast pressure; microstructure of the coating shows oxides, eutectics, etc. The coefficient of thermal expansion of the sprayed brass between 20° and 70° C. was nearly 10% smaller, apparent specific gravity was also about 15% smaller, but the electric resistance was about 3 times greater than the corresponding properties of ordinary brass of the same composition. Hardness depended noticeably upon the air blast pressure; tensile strength, elongation and impact value of the coating were small. The adhesive strength of the coating sprayed on soft steel depended considerably on the initial surface condition of the steel. NS (7b)

Production Methods for Composite Steels. *Iron Age*, Vol. 142, Aug. 4, 1938, pp. 33, 39. Practical. Considerable advance has been made in the making of composite steel stock especially in the elimination of oxidation, as is successfully done by the Armstrong process. Corrosion and heat-resisting clad plates are first electrolytically pickled to remove oxide. While still wet, Fe is electrodeposited to a thickness of 0.015 in. on the surface to be clad with the special steel. Previous to rolling, component layers are joined by fusion welding to exclude furnace gases from areas to be welded. In casting, the Armstrong method has also been used to advantage. VSP (7b)

The Fight Against Silicosis in the Metal Industry (Die Bekämpfung der Staublungenerkrankung in der Metallindustrie) *Oberflächentech.*, Vol. 15, Sept. 20, 1938, pp. 180-181. Review. Silicosis develops in men working in sandblasting or grinding of metals more rapidly than in miners. Means for preventing the inhaling of the fine metal dust, adequate equipment, and clinical aspects are briefly discussed. Grinding wheels of artificial stone are much more sanitary, as the dust contains no free SiO_2, which is the main cause of silicosis. Wherever possible, artificial stones should be used. Ha (7b)

Announcing

SAMPLING AND ANALYSIS OF CARBON AND ALLOY STEELS

Prepared by the Chemists' Committee of The Subsidiaries of the U. S. Steel Corporation

EXACT CHEMICAL SPECIFICATIONS govern the manufacture and purchase of steel products. To insure compliance with these specifications, standardized and minutely accurate analytical procedures are essential. The necessity for standardization of methods becomes evident when it is realized that corrosion and heat resistance and other specific properties, are obtained by the addition to steel of such elements as nickel, chromium, molybdenum, etc., sometimes in almost microscopic percentages. When determinations accurate to the third decimal place are demanded, no tolerance can be allowed for the slightest variation in procedure.

AUTHORITATIVE AND DETAILED PROCEDURES are simply and lucidly presented in this volume. Its aim is to enable any chemist to analyze steels with meticulous accuracy, and it accomplishes this aim by eliminating as far as possible the "human equation." Careful observance of the directions and cautions given will not only reduce the time of determination to a minimum, but will yield absolutely reliable results. This will be of tremendous value to the relatively inexperienced chemist who may have occasion to make check analyses of steel shipments. Since large-scale production of alloy steels is a comparatively recent development, the need for authoritative methods is greater now than ever before, and will be constantly increasing. Everyone interested in testing and analytical work should possess this volume.

SUBSIDIARIES OF THE U. S. STEEL CORPORATION have developed many new methods over a period of years. Their book, 356 pages in length, comprises the most complete and modern body of information on steel analysis that has ever appeared. This corporation has long been prominent in making available to industry everywhere information dealing with sampling and testing of materials used and produced in the iron and steel industry. Eight volumes, totalling 17 editions, published directly by the U. S. Steel Corporation at intervals during the last 30 years, have met an enthusiastic reception the world over, not only within the industry but in scientific libraries and universities. The Reinhold Publishing Corporation has been entrusted with the publication and sale of this latest volume.

THE SCOPE OF THIS BOOK *includes approved procedures for sampling mill products, and for determining all the elements that may occur in steel under any conditions of combination. Methods are given for such infrequently* occurring elements as beryllium and cerium. The first appendix article describes three recent new procedures for determination of sulfur by combustion, most desirable when it is impossible to obtain the sulfur content by older methods. The skeleton table of contents below gives a general summary of the subjects covered.

Because of the extent of the full Table of Contents, only Chapter Headings are given.

Sampling.
Qualitative and Quick Tests for Identifying Various Types of Steel.
Methods of Analysis.
Chemical Separations.
Determination of Manganese.
" " Phosphorus.
" " Sulphur.
" " Silicon.
" " Copper.

REINHOLD PUBLISHING CORP., 330 W. 42nd Street, New York, U. S. A.

Metallic Protective Coatings on Aluminum Alloys. *Light Metals,* Vol. 1, Sept. 1938, p. 283. Review. One of the earliest duplex metal products was Ag on Cu, produced by casting the cladding metal (Ag) around a core of Cu as a basis metal. Al cladding has been in use only for about 15 years. Two early methods of cladding Al alloys with corrosion resistant pure Al were: (1) Casting high-purity Al around the Al alloy, and (2) hot rolling or pressing the 2 materials together. A thin cladding of pure Al is desirable on account of the lower strength of pure Al, but the coat cannot be too thin or its protective value will be reduced. One proposed method for using inferior or secondary Al sheet for cooking utensils, a field in which costs must be kept low, is to weld several sheets together in the expectation that impurities will not form a continuous and inter-connecting path from one side to the other. If a heavy metal is used as a cladding material on Al, different techniques are possible, since the heavy metal usually has a higher melting point than Al. Superheating of the heavy metal above the melting point of the Al, followed by placing the 2 pieces in contact, is sometimes sufficient to melt the Al without heating it directly. The Al is melted only near the surface of contact, and since the body of the Al remains relatively cool, the 2 may be rolled together without too much deformation of the Al. Certain elements, particularly Cu, should not be permitted to diffuse into a clad coating of Al as the corrosion resistance is thereby lowered. A third metal, sandwiched in between the basis metal and the cladding, has been recommended for this purpose. An oxide film on the basis metal prior to the cladding has been suggested, but no details are available. In Germany a process has been developed in which an Al alloy containing Mn and Mg (which are not detrimental to corrosion resistance) is sandwiched in between the basis metal, containing Cu, and the pure Al coating. The Cu diffuses from the basis metal to the intermediate layer, but not to the outside layer. Hard-facing of light alloys is necessary, for example, in sludge scrapers or in implements subject to heavy abrasion. In one device of this kind developed by Schlüpmann, the hard metal is melted on a sump or refractory dish on one edge of the Al alloy plate to be hard faced. A gas torch is used to melt the hard-facing alloy which, after melting, runs onto the surface of the work.
AUS (7b)

Care of Hot and Solvent Vapor Degreasers. E. V. D. WALLACE (Mechanical Process Corp.) *Metal Cleaning Finishing,* Vol. 10, Sept. 1938, pp. 634-638. Discussion. Care should be taken to prevent fumes from entering the work room. The machine should be protected from drafts and if necessary provided with a draft guard and ventilating system. It should not be located near heat-treating furnaces or welding machines because escaping vapor is decomposed by heat with the production of obnoxious fumes. Loss of solvent can be minimized by not cleaning too large a load of parts at a time since this results in the displacement of a large volume of air saturated with solvent, and by letting bulky parts or baskets of small parts hang above the tank for 30 sec. before removal, so that the solvent can drain back into the tank, either as vapor or liquid. The degreaser should be cleaned every 2 weeks and the solvent should be neutralized with alkali and distilled. Al dust from the cleaning of Al parts should be removed as it may react with the solvent. Deposits of dirt should be removed from the heating units. AB (7b)

"Superfinished" Surfaces. A. F. DENHAM. *Am. Machinist,* Vol. 82, July 27, 1938, pp. 678-680; Aug. 10, 1938, pp. 722-725; *Machinery, N. Y.,* Vol. 44, Aug. 1938, pp. 858-864. Original research. "Superfinish" is a term connoting an extremely fine surface finish produced on any kind of surface by a combination of short motions, light abrasive pressures, slow abrasive cutting speeds, hard abrasive stones and a lubricant of proper viscosity. The process is said to eliminate all scratches and surface defects left by previous operations without creating new scratches. The mechanism of the process, as it differs from ordinary polishing methods, is explained. Numerous applications are described.
Ha (7b)

Preparation of the Surface of Steelwork Prior to Painting. *Iron Steel Inst., Fifth Report Corrosion Committee,* 1938, pp. 351-368. Discussion and research. Methods of removing scale are discussed. Various phosphate treatments for use prior to painting are mentioned. Some experiments on scale removal with wire brushes are described. Although mill scale can be completely removed with brushes, the method does not seem to be entirely practicable. Plans for investigating the effects of different pickling methods on paint life are described. JLG (7b)

Descaling and Derusting by Sandblasting (Das Entzundern und Entrosten mit dem Sandstrahlgebläse) *Oberflächentech.,* Vol. 15, Sept. 20, 1938, pp. 181-182. Cleaning of metal surfaces from rust and scale before putting on a protective coating is done most satisfactorily by sandblasting. Installation must be selected according to purpose. Sharp quartz sand of 1-1.5 mm. grainsize is most advantageously employed under a pressure of 1-2 atm., the energy required amounts to 2.5-7 HP and 3-12 m.³ air/min., according to capacity. Examples are described. Ha (7b)

Spent Pickle Liquor. *Steel,* Vol. 103, July 25, 1938, pp. 35-36, 61. Industrial note on new process for treatment of spent pickle liquor. This is collected in a storage reservoir, from which it is pumped into 2 or more precipitating tanks. Each batch, as
1 treated, is neutralized with Ca or Mg alkalies, such as dolomitic or ordinary limestone, at 150° F. Batches remain in tanks for about 1 hr. Precipitate, consisting of Fe $(OH)_3$ and $CaSO_4$, is
— removed in filter-presses, charged into a pug-mill, de-aired, oven-dried at 175° F. and cut to form or ground up. For certain applications, fiber is introduced into batches in the precipitating tanks. Effluent from filter-presses is clear, uncontaminated H_2O, which can be discharged into sewers or streams, or can be used in plant
2 operations. Precipitate, designated "Ferron," makes an excellent insulating material, which is fire-proof and termite proof, will
— not warp, and can be easily cut, sawed and machined. It is homogeneous and solid appearing, but extremely porous. It removes H_2S and other S compounds from gases and liquids, and provides a good filtering mass for many operations. A plant having a capacity to transform 10,000 gal. of spent pickle liquor per day into 25 tons of insulation costs about $50,000. MS (7b)

3 **Mirrors of Motordom.** A. H. ALLEN (Staff) *Steel,* Vol. 103, Aug. 1, 1938, pp. 23-24. Review. To enhance wearing qualities of engine parts subject to wear, they are being subjected to treat-
— ment similar to the so-called rustproofing process applied to body sheets before painting. One large company is substituting the Granodizing process for present Cu plating used on camshafts. It is claimed that the thin phosphate coating deposited on the part provides a semiporous surface for holding lubricant, thus increas-
4 ing wear resistance. Present plating tanks will be used, with electrical system removed except for cleaning. For reducing wear to a minimum, Chrysler is finishing certain parts with a special type of machine equipped with abrasive tools (350-500 grit) and combining short oscillating motion with light abrasive pressure
— and a lubricant of proper viscosity. Surface of exceptional smoothness is claimed to result. Ford has overcome wear on cylinder walls at point where tops of pistons are at upper limit of stroke, by inserting narrow liners of 3.5% Ni iron. MS (7b)

5 **The Conception, Development, Equipment and Measuring Methods for an Entirely New Surface Finish Method—Superfinish.** WILLIAM F. SHERMAN (Staff) *Iron Age,* Vol. 142, Sept. 1, 1938, pp. 18-23; Sept. 8, 1938, pp. 40-45; Sept. 22, 1938, pp. 57-61, 90. Practical description of a new surface finish produced
— upon flat, internal, external, round and other types of surfaces by a combination of short motions, light abrasive pressures, slow abrasive cutting speeds, hard abrasive stones and a lubricant of proper viscosity that eliminates scratches and surface defects created by pre-
6 vious mechanical operations, without creating scratches or defects. Presents also new conceptions, definitions of terms used, and compares the use of this technique with conventional methods of finish-
— ing automotive parts. Finally deals with measurement of temperatures on metal surfaces, hardness ductility, strength of oil films and other lubricant specifications which must be taken into account with this process. VSP (7b)

7 **The Metalastik System of Bonding Rubber and Metal.** *Engineering,* Vol. 146, Sept. 30, 1938, p. 391. Practical discussion. Detailed description of the process is not available. It consists, in
— general, in plating of metal parts, by electrodeposition, with a film of an alloy having the appearance of light colored brass. The surface is perfectly smooth, yet is of such structure that the rubber, when vulcanized, may be said to fuse homogeneously with it. Results of tests conducted on the product are given. It is used for damping torsional oscillations and vibration in continuously moving machinery, and was developed by Metalastik, Ltd., Lancaster, Eng.

Plastic Coatings Applied to Pipes Automatically by New Process. J. EDW. TUFFT. *Steel,* Vol. 103, July 11, 1938, p. 58.
— Describes automatic, gas-engine driven machine for placing concrete coating on pipe-lines to reinforce pipe and to protect it against corrosion, invented by Thomas H. Wilson. Coating is applied in trench, without disturbing pipe-lines, by a rubbing pressure without use of supports or forms of any kind. Normal speed under average
9 conditions is 200-300 ft./hr. for 6-in. pipe, and 24-60 ft./hr. for 24-in. pipe. Thick coatings, ¾ in. on 3 in. pipe up to 2 in. on 18-in. pipe, are recommended. MS (7b)

Bars and Shapes Tumbled Free of Rust and Scale. *Iron Age,*
— Vol. 142, July 14, 1938, pp. 33-34. Practical description of a patented machine and process for cleaning rust and scale from steel bars, shapes and pipe rapidly at a cost of about $1 per ton. On some types of material it is as efficient as pickling or sand blasting.
10 This process is said to leave the steel so clean that it can be cold drawn, machined, welded, galvanized, etc., without further cleaning. Fine coke or blast furnace slag free from Fe is used both as an abrasive and a cushion for the material. Developed by J. M. Hebbish and J. K. McCahan. VSP (7b)

Methods and Equipment. Physical and Mechanical Property Testing. X-Ray and Magnetic Inspection. Spectrographic Analysis.

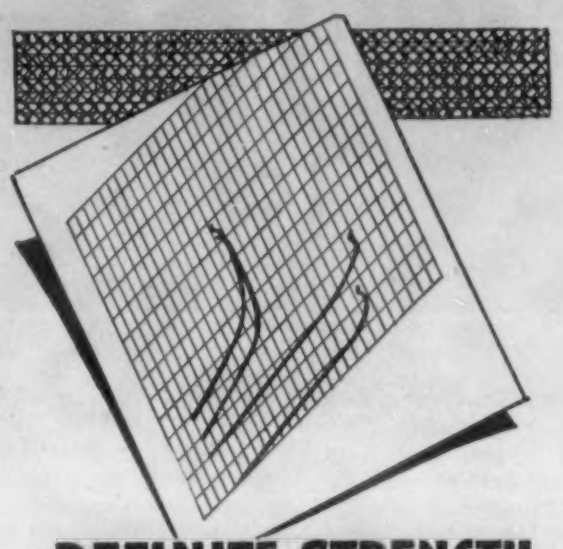
W. A. TUCKER, L. S. REID AND G. R. HARRISON, SECTION EDITORS

Standardization of the Notch Impact Test (Beitrag zur Normung der Kerbschlagprobe) V. JARESZ. *Czechoslovakische Normungsgesellschaft & Czechoslovakischen Verband für Materialprüfung,* Prague, 1937, 55 pp. Review. The various types of steels tested and the various types of notch impact samples common in different countries are discussed. The V-notch permits better judgment of the notch sensitivity of steel than the round. The type of V-notch is not so critical; the English standard notch is preferred. The decision as to the best round notch is difficult; the 5 mm. round notch, although standardized in France, is disadvantageous as the cross-section is too small and the gradation of different steels is poor. Of the other types of notches, Mesnager 2 mm. deep and Moser 3 mm. deep, the latter proves better for plain C steels. For heat-treated alloyed steels both types of notches are equally suitable. International standardization of the French standard specimen is the least advisable. These as well as earlier Italian investigations by Steccanella (*Met. Ital.*, Vol. 24, 1932, No. 5, and Teoderesco, *Metals and Alloys,* Vol. 4, Aug. 1933, p. MA 249) proved a considerable fluctuation of the notch toughness ratio of the Mesnager and Moser specimens. Therefore, there is no general possibility of transforming Mesnager into Moser data. To a certain extent, however, this is possible with good normal steel quality. GN (T-8)

Non-destructive Testing by Gamma Rays. J. G. HALL. *Foundry Trade J.,* Vol. 59, Sept. 1, 1938, pp. 157-158. Review Differences between X-rays and γ-rays, apparatus and methods, influence of distance, density considerations, time-temperature method, etc. are discussed. γ-rays are produced in the disintegration of Ra. Whereas the limit for the practical use of X-rays for testing purposes is in the region of 4 in. of steel, γ-rays have been found effective up to 10 in., with a possible extension to 12 in. A capsule of less than ¼ in. diameter contains enough radio-active substance for the examination of any commercial object. The apparatus and methods for γ-radiography are very simple. A small container of radio-active material, radium sulphate sealed in small Ag capsules, is supported rigidly in front of the object to be inspected, and X-ray films in light-tight holders are fastened to the back of the object. Ra emits α, β and γ rays, all of which are inimical to the health of the workers. Ra should be stored in a safe of solid Pb of some 6 in. thickness in all directions, should be handled with tongs or strings, never touched directly with the hands, and should not be approached nearer than a distance of 10 ft. unless shielded by heavy castings. AIK (T-8)

The Effect of Sample Size and of the Dependence of Excitation of the Line Intensity on the Mean Error in Spectral Analysis (Der Einfluss der Probengrösse und der Anregungsabhängigkeit der Linienintensität auf den mittleren Fehler bei der Spektralanalyse) G. THANHEISER & J. HEYES. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch., Düsseldorf,* Vol. 20, No. 13, 1938, pp. 153-166. Research. The effects of electrode diameter and of the selected pairs of lines upon the average variations in spectrum analysis were investigated on a steel of 0.23% C, 0.23% Si, 0.50% Mn, 0.010% P, 0.028% S, 2.75% Ni and 0.68% Cr. The electrodes were of 1-36 mm. diam. The least variations of intensity were found in electrodes of 3-5 mm., the best obtainable variations were about 3%. 13 references. Ha (H-8)

Comparisons of Non-destructive Testing by X-ray Shadow Pictures and by Magnetic Inspection (Vergleichende Betrachtungen der zerstörungsfreien Werkstoffprüfung durch Röntgenschattenbild und durch magnetische Prüfung) M. v. SCHWARZ. *Berg- u. Hüttenmänn. Monatsh. Montan. Hochschule Leoben,* Vol. 86, July 1938, pp. 189-193. **X-ray and Magnetic Tests of Welds (Röntgen- und Magnetprüfungen von Schweissungen)** R. BERTHOLD. *Ibid.,* pp. 193-195. Review. Both methods are critically discussed, and a great many examples are reproduced photographically. The magnetic method is considered superior to the X-ray method in testing a material for cracks (particularly very fine ones) as they can more readily be detected by the deviation of the magnetic lines of force. Apparatus is described. Ha (T-8)



Proposed Tentative Method for Bend Testing of Wire. *Am. Soc. Testing Materials,* Preprint, June 1938, 5 pp. Appendix to Report of Committee B-4 on Electrical-heating, Electrical-resistance and Electric-furnace Alloys. Specifications are given for a test intended to evaluate the "temper" of wire for radio tubes, incandescent lamps and electrical resistance purposes, in terms of the energy expended in producing a given amount of bending. It is intended for use on wire from approximately 0.010 in. to 0.117 in. diameter. The test comprises clamping a specimen of wire rigidly at one end, subjecting it to a bending force and measuring the energy absorbed by the specimen per unit of bending. The bending force is applied by means of a loading system such as a pivoted, weighted arm actuated by gravity and carrying a "bending die" which maintains contact with the specimen during the bending operation. Thus, the energy absorbed by the specimen may be calculated from a knowledge of the magnitude and location of the unbalanced weights and the angle through which the moving elements turns from a predetermined initial position until brought to rest by the resistance of the specimen. VVK (T-8)

Secondary Radiation in the Radiography of Aluminum, Steel and Lead. HERMAN E. SEEMANN (Kodak Res. Labs.) *Am. Soc. Testing Materials.* Abstract Preprint, June 1938. Comparatively simple tests indicate that secondary radiation interferes seriously with the observation of detail in a radiograph. Curves show that, for a given density, there is a progressive decrease in contrast with increase in proportion of diffuse secondary radiation. In the experiments reported, exposures were made with and without Pb foil intensifying screens to see how effective these screens are in removing secondary radiation. The results indicate that there is almost a linear increase in proportion of secondary radiation with increase in thickness of the material. Pb foil screens may remove almost ½ of the secondary radiation. Hence, their use is advantageous but still leaves something to be desired. Some difference in the amount of secondary radiation would be expected at different kilovoltages but none has been detected. This may be partially due to compensating effects but the kilovoltage range that can be used advantageously for a given specimen in practice is so small that the difference is probably negligible. VVK (T-8)

Spectrographic Analysis at a Large Technical Laboratory. ABRAHAM MANKOWICH. *Metals and Alloys,* Vol. 9, June 1938, pp. 131-137. Descriptive. Considerable time in analysis is saved on the determination of minute impurities in metals and many chemical compounds by analyzing the spectrographic results of vaporizing a small volume of solution of the unknown in a direct current arc. The size of the liquid sample is dependent upon the concentration of the substance being analyzed and also upon the substance itself. The unknown spectrum should be compared with that of a standard solution for match. The density of the impurity lines in the unknown and standards should be compared using a densitometer. For certain determinations, such as Ca and Na in $BaNo_3$, the C arc was found to be unsatisfactory; therefore, a Cu electrode was used in place of the graphite. Details of application of spectrographic procedure to the analysis of a wide variety of commercial metals and alloys are given. WLC (H-8)

Determination of Boron in Steel and Cast Iron. JOHN L. HAGUE & HARRY A. BRIGHT. *J. Research Natl. Bur. Standards,* Vol. 21, Aug. 1938, pp. 125-131. Original research and development. A method is described for the determination of small amounts of B in steels and irons. The procedure calls for (1) solution of the sample in HCl followed by oxidation in H_2O_2, (2) distillation of methyl borate (Chapin's method), and (3) titration of B $(OH)_3$ with NaOH in the presence of mannite. Se and Te do not interfere, but Ge, a very minor constituent rarely present in ferrous metals, causes small positive errors. Method accurate to ± 0.002% for alloys containing from 0.005 to 0.1% B. WAT (T-8)

Spectrographic Examination of Assay Beads for Platinum, Palladium and Gold. J. SEATH & F. E. BEAMISH (Univ. Toronto) *Ind. Eng. Chem.,* Anal. Ed., Vol. 10, Sept. 1938, pp. 535-537. Original research. The authors suggest the preparation of duplicate assay beads for preliminary spectrographic examination which may effect a time-saving in the wet analysis for the precious metals. If Pd, Pt and Au lines are absent in the bead spectrum, the separation procedure may be omitted. Details are given. MEH (H-8)

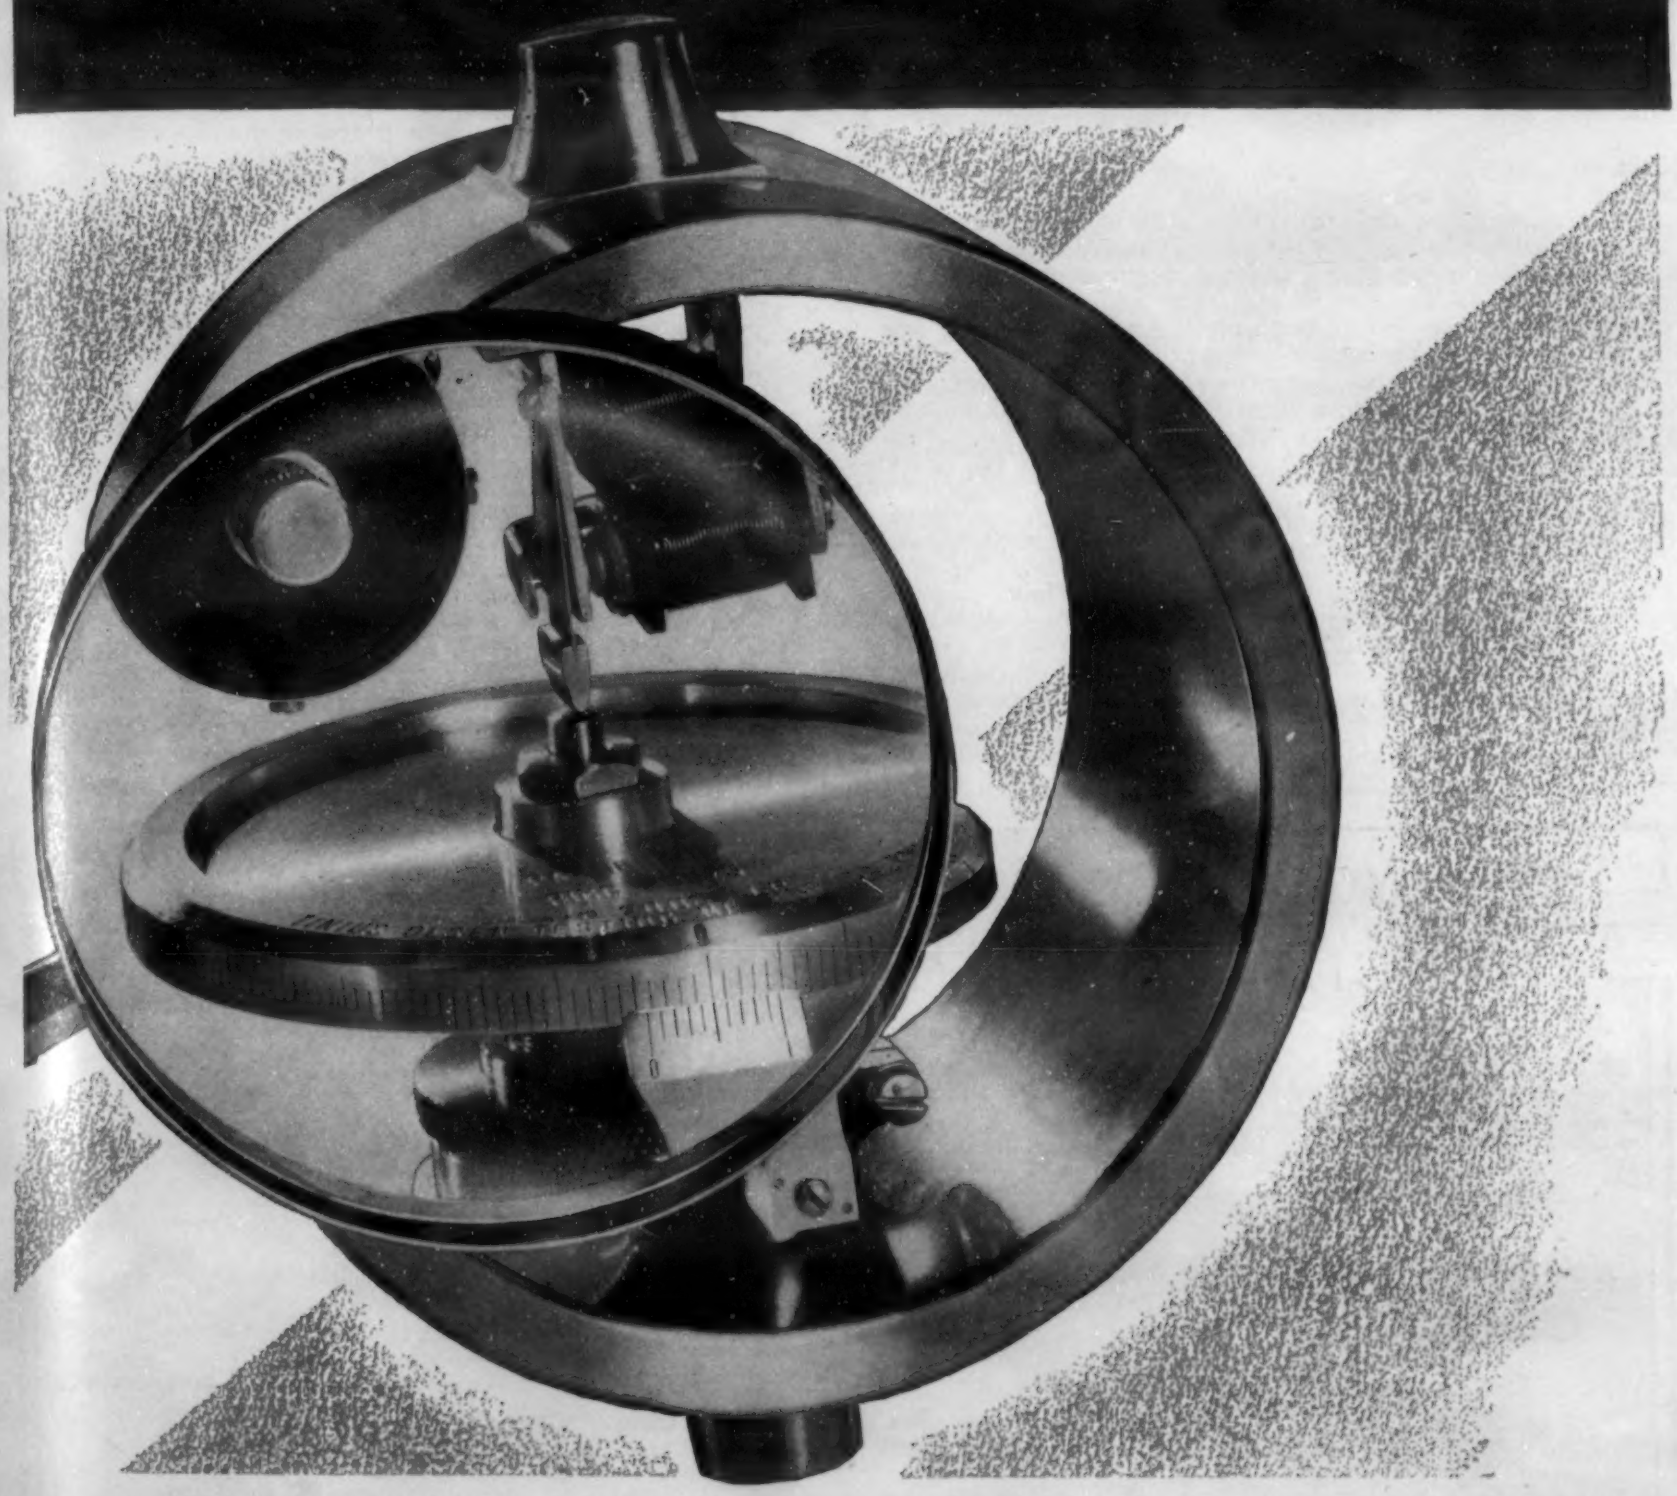
1 **Elimination of Scrap in Drawing Hollow Bodies of Thin Sheets, with Special Reference to Available Deep Drawing Testing Methods** (Die Beseitigung des Ausschusses beim Ziehen von Hohlkörpern aus dünnen Blechen unter besonderer Berücksichtigung der bisher bekannten Tiefzieh-Prüfverfahren) GERHARD OEHLER. *Beiträge zur Wirtschaft, Wissenschaft u. Technik d. Metalle u. ihrer Legierungen,* No. 5, 1938, pp. 1-87. After giving a detailed account of the various factors playing a role in deep drawing processes, such as lubrication, drawing power, holding pressure, fillet at the drawing edge, drawing gap, drawing speed and graduation of draws, the author describes his own experiments in deep drawing 7 different types of sheets: Brass sheet, Al sheet, tin-plate and 4 different types of common deep drawing Fe sheets, and compares the practical results with the quality standards established by the various methods of testing deep drawability. A most comprehensive critical review of the testing methods is given. With the cupping methods (Erichsen, Olsen, Guillery, Amsler, Avery, etc.) the minimum size of the sample should be 3 times the drawing edge diameter, *i.e.* for the Erichsen method with 27 mm. interior drawing edge diameter, a square sample of 90 mm. side length should be applied. Otherwise too large deep drawing values result. The type of lubricant has considerable effect on the result. With vaseline and tallow higher values result than with common machine grease lubrication. The mathematical evaluation of the AEG testing method according to Schmidt (*See Arch. Eisenhüttenw.,* 1929, No. 3, p. 213) was critically investigated. The assumption that the punch pressure increases with the diameter ratio β of blank diameter to drawing diameter holds true for brass and Al sheet, but only approximately true for Fe sheet. By determining the β values of different sheet types and sheet thicknesses, quality standards of deep drawing sheets can be established. Furthermore, the graduation of the tools can be determined. Vice versa, with given tools, the sheet quality required to attain the desired β values can be established. The change of the β value conforms to the longitudinal elongation and the circular elongation increase, but not in regard to size. The longitudinal and the circular elongation, as determined by the Siebel-Pomp widening method, give similar values. The grain can be studied better by the Siebel-Pomp method than by the common cupping methods. The practical drawing tests were in best agreement with the elongation measurements in tensile tests; drawing tests according to the AEG method gave results in accordance with the results of the Schmidt and of the Siebel-Pomp widening tests. The common cupping tests and bending tests range second in conformity with the practical results. The folding test and hardness measurements permit no judgment of deep drawing properties. Neither decrease nor increase in sheet thickness, nor the deviation of the actual drawing depth from the depth calculated permit accurate conclusions as to the deep drawability of a sheet. The practical tests show different behavior of the various drawing shapes with the various materials. It could not be proven that certain sheet testing methods are better fitted for certain drawing shapes than others. GN (T-8)



7 **Spectrographic Analysis of Steel by the Solution Method and its Application to the Investigation of Dendritic Structure in Steel Ingots.** Y. KANAMORI. *Nippon Kinzoka Gakukai-Si,* Vol. 2, Aug. 1938, pp. 413-418. In Japanese. Original research. A new solution method was studied so that analysis could be made even when sample is small in quantity or relatively high in alloying elements. A sample of 0.2 g. of Fe is dissolved in 5 cc. of HCl solution and compared spectrographically with standard solutions of the same concentration. The quantity of the element determined was varied in the range of 0.04-0.6 mg./cc. Anaylses for dendritic segregation in Ni-Cr and Ni-Cr-Mo steel ingots showed that Ni, Cr and Mo are richer in the fillings of dendrites than in the branches. NS (H-8)

9 **The Relation between the X-radiograph of a Weld and Its Tensile Strength (Der Zusammenhang Zwischen dem Röntgenbild einer Schweissnaht und ihrer Zugfestigkeit)** E. A. W. MÜLLER. *Arch. Eisenhüttenw.,* Vol. 12, July 1938, pp. 25-26. Original research. Electric-arc V and X welds in structural steel plates 10-16 mm. thick were made, the welded seams X-rayed, and tensile tests made. The effect of various types of defects in lowering the tensile strength is shown by radiographs and accompanying values of tensile strength. The effects of smaller pores and inclusions were unnoticeable; the main causes in lowering the tensile strength were discontinuities in the welds, absence of proper beads, and large pores. SE (T-8)

10 **A Level-bubble Strain Gage.** REX L. BROWN (Univ. Illinois) *Am. Soc. Testing Materials,* Preprint, June 1938, 2 pp. This paper describes a strain gage that has a sensitivity to seven millionths of an in. A 5-sec. level bubble is used as a measuring device. It is fastened to the moving leg of the instrument, and its level changes with strain along its gage length. The instrument is adapted for use along horizontal gage lines, and has been used to measure very small strains in the concrete of reinforced-concrete slabs. VVK (T-8)

Electrochemical Processes and Their Use for the Absolute Determination of Metal Surface Areas (Elektrochemische Vorgänge und ihre Auswertung zur Absolutbestimmung von Metalloberflächen) OTTO ERBACHER. *Chem. Ztg.*, Vol. 62, Aug. 20, 1938, pp. 601-604. Original research. Electrolytic deposition without application of electrical energy is a spontaneous interchanging of nobler ions with less noble metal atoms, the deposition of the nobler ions being brought about by local elements. There is another type of deposition, in which the interchange takes place at the very same spot, giving a mono-atomic coating. This occurs when the velocity of solution of the nobler atoms is greater than the velocity of discharging of the nobler ions (by local elements). This process allows the experimental determination of the absolute area of metal surfaces. It is, moreover, possible to determine the active area of noble metals by loading them with H and using the activated H for the electrochemical interchange with nobler ions. RPS (T-8)

A New Smoothness Tester. V. SEKIGUCHI & I. HASEGAWA. *Mech. Eng.*, Vol. 60, Oct. 1938, pp. 751-755. After a brief review of methods for measuring roughness and smoothness of a surface, a new method is described that uses a needle set at an angle of about 80° to the normal line on the surface to be tested, with the curved part near the point of the needle in contact with the surface. By means of a rectilinear reciprocating motion, the needle vibrates along the uneven parts of the surface; the vibrations are transmitted to one end of a pair of Rochelle salt crystals, the other end being fixed, thus generating piezoelectricity. The piezoelectric variations are recorded in the usual way; the amplitudes show the degree of smoothness. The practical arrangement is described in detail and examples of measurements given. Ha (T-8)

Preliminary Lists of Terms for the Arc and Spark Spectra of Tungsten. DONALD D. LAUN. *J. Research Natl. Bur. Standards*, Vol. 21, Aug. 1938, pp. 207-224. Original research. 8a. Fatigue Testing

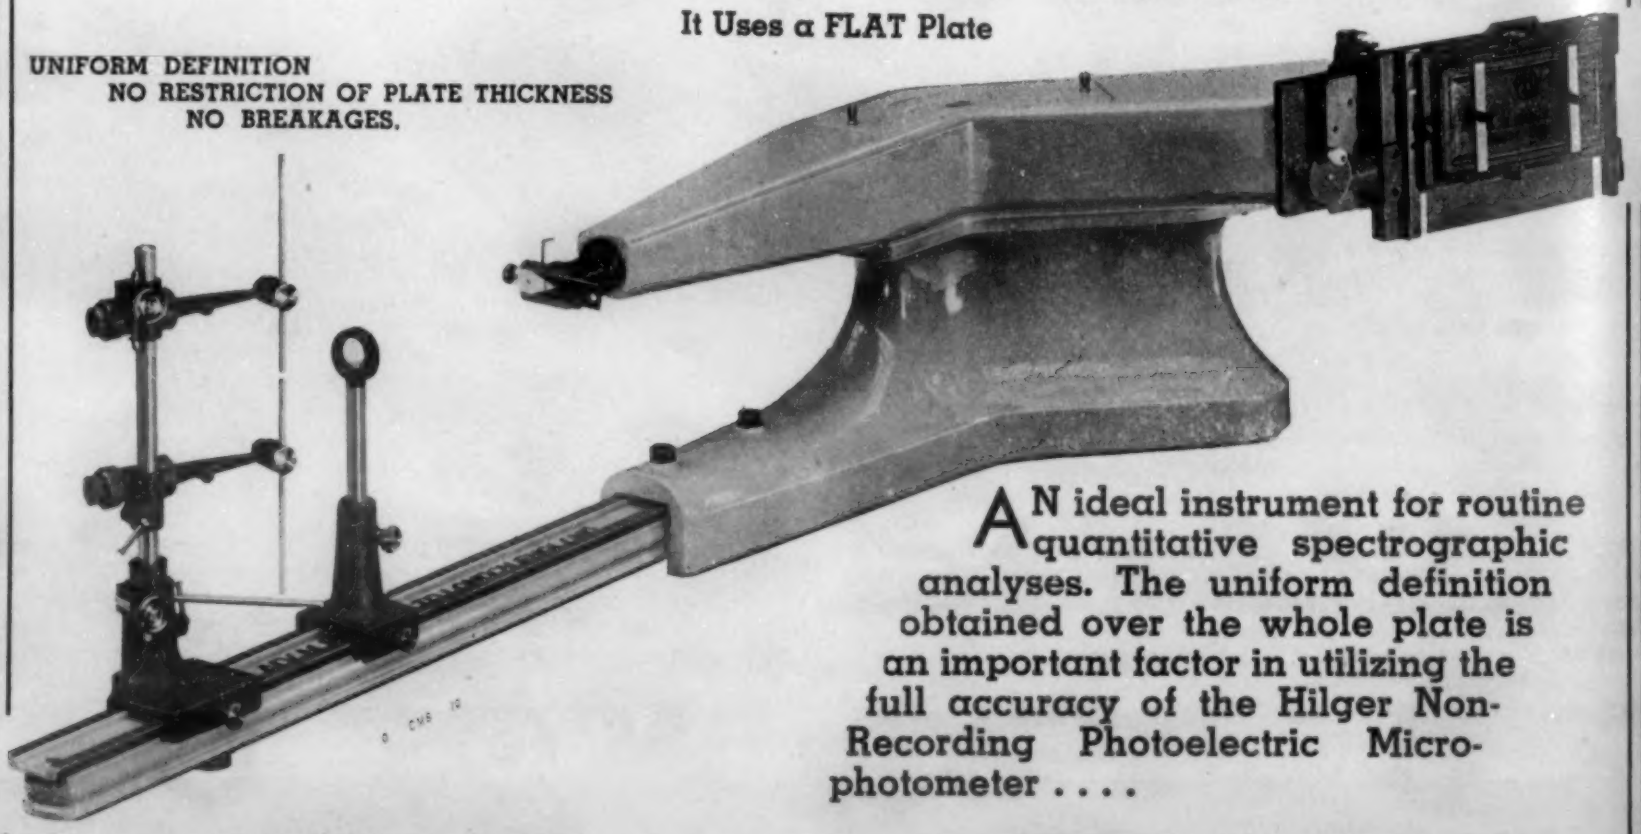
H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Influence of Round Notches and Drilled Holes on the Repeated Bending Strength of Bars with Reduced Sections (Einfluss von Hohlkehlen an abgesetzten Wellen und von Querbohrungen auf die Biegewechselfestigkeit) E. LEHR & R. MAILÄNDER. *Arch. Eisenhüttenw.*, Vol. 11, May 1938, pp. 563-568. Original research. The effect of round filleted reduced sections and drilled transverse holes in test pieces 9 and 30 mm. in diameter on the endurance limit in reversed bending tests on various C and alloy steels was determined. For equally filleted reduced sections and equal diameter holes per diameter of specimen, the endurance limit was higher the harder the steel. With abruptly reduced sections, however, the endurance limit was not much higher for the harder steel. That is, the per cent decrease in endurance limit because of notches and holes was greater in the harder steels. This decrease was small, however, with well-filleted notches. The notch effect was greater in thicker specimens than in thinner. The effect of specimen size was about the same in the different steels, this being in general insignificant except in the case of sharply notched specimens. SE (8a)



Dynamic Tensile Properties of Light Metals at Low Temperatures (Dynamische Festigkeitseigenschaften von Leichtmetall-Legierungen bei tiefen Temperaturen) KARL BUNGARDT. *Z. Metallkunde*, Vol. 30, July 1938, pp. 235-237. Experimental. Fourteen common alloys of Al and Mg were tested at room temp., —35° and —65° C. The bending endurance limit increased with decreasing temp., especially for Al-Cu-Mg. Al — 4.68% Mg, and Mg-Mn alloys, while there was very little temp. effect in Al alloys with higher Mg content or the Mg-Al alloys. The notch sensitivity, with the exception of the Al alloys containing 7.73% Mg and 0.98% Zn which were unaffected, became greater at low temp. GD (8a)

Fatigue Tests of Riveted Joints. W. M. WILSON & F. P. THOMAS. *Univ. Illinois Eng. Expt. Sta.*, Vol. 35, May 31, 1938, Bulletin 302. Original research. For all fatigue tests endurance limit was determined on the basis of 2,000,000 cycles of stress. Tests in which rivets failed showed an endurance limit of the order of 30,000 lb./in.^{2} shearing stress for cycles of stress varying from zero to a maximum in one direction. Tests under reversed stress gave a wide scatter of results ranging from 15,000 to 30,000 lbs./in.^{2} Rivets stood up better under reversed stress in joints with plates having milled ends. The fatigue strength of high-strength bolts, with nuts screwed up to give high bolt tension was as great as that of well driven rivets. There was some evidence that the ratio of fatigue strength under reversed stress to fatigue strength under repeated stress is less for rivets than it is for the plates of a riveted joint. Fatigue tests in which failure took place in the plates gave some evidence that the influence of range of stress in a cycle on endurance limit may be represented by the Moore and Kommers formula $FL' = \frac{3\,FL}{2 - r}$ in which FL is the endurance limit for completely reversed stress r is the ratio of minimum to maximum stress, and is negative for a complete or partial reversal, and FL' is the endurance limit for any particular value of r. Increasing the ratio of unit bearing to unit tension from 1.17 to 2.35 did not affect the endurance limit for joints with high friction between plates. There was some evidence that decreasing the transverse distance between the rivets from 7 in. to 3⅜ in. increased fatigue strength of carbon-steel plates. The method of making rivet holes—punching, sub-punching and reaming, or drilling—did not appreciably affect the fatigue strength of either carbon steel or silicon steel plates for holes 1 1/16 in. diam. and plates ½ in. thick. The fatigue strength of plates in a riveted joint of balanced design under stress varying from 0 to max. tension was approx. 26,000 lb./in.^{2} for carbon steel, silicon steel, or nickel steel. Fatigue strength obtained from tests of small polished specimens is unreliable for design purposes owing to the stress-raising effect of rivet holes and rolled surfaces. The higher the strength the greater its sensitivity to stress raisers.
Ha + HFM (8a)

Bending-Fatigue Strength of Welded Rails (Ueber die Dauerbiegefestigkeit von geschweissten Schienen) O. GRAF. *Autogene Metallbearbeit.*, Vol. 31, Aug. 15, 1938, pp. 255-266; Sept. 1, 1938, pp. 271-279. Unusually comprehensive investigation of new and used rails with regard to endurance bending and tensile strength for straight butt-, oblique butt-, welded and lap joints. Welded joints were far superior to lap joints. Rails from various sources showed originally about 32,000-41,000, and one 60,000 lbs./in.^{2} bending-fatigue strength for 1 million reversals. In used rails, which were slightly rusty and showed notches caused by traffic or handling, the bending-fatigue strength was much reduced, sometimes to only 15,000 lbs./in.^{2} due to the presence of notch effects. The tests are described in great detail and illustrated by many photographs of structure, fractures and constructional details. 20 references. Ha (8a)

Corrosion Fatigue. A. E. JENSEN. *J. So. African Inst. Engrs.*, Vol. 36, July 1938, pp. 273-281. Survey. Experimental results of many investigators on the effect of corrosion on the endurance of materials are considered, particularly on ferrous metals. The types of machines employed for the determination of endurance limits are described and illustrated. There is a serious effect of a mild corrosive agent such as 0.2% H_2SO_4 solution on mild steels while undergoing cyclic variation of stress. Such weakening is common to practically all materials. The loss in fatigue resistance is not proportional to the amount of material converted into the corrosion-product. WHB (8a)

The Bending Strength of Lead and Lead Alloys (Zur Schwingungsfestigkeit von Blei und Bleilegierungen) KLAUS v. HANFFSTENGEL & HEINRICH HANEMANN. *Z. Metallkunde*, Vol. 30, Feb. 1938, p. 51. Experimental. Alternating cycle bending tests were made on (a) 99.99% Pb, (b) Pb alloyed with 1.2% Sn, 0.2% Cd, and 0.1% Sb, (c) Pb with 0.07% Ca, and (d) Pb with 1% Sb, 0.05% As. The tests, which were carried only to ten million cycles (at 12 cycles per second) showed that the bending strength was directly proportional to the hardness, the alloys ranging themselves in the order listed with pure Pb the weakest. GD (8a)

Eudurance Strength with Alternating Temperatures (Dauerstandfestigkeit bei wechselnden Temperaturen) GEORG WELTER. *Z. Metallkunde*, Vol. 30, June 1938, pp. 195-198. Experimental. Endurance tests with constant load and temp. alternating between −60° and +70° C. were made on Cu wires, because of the need for such data for high tension lines and similar installations. The effect is to increase the rate of the initial rapid elongation over that normally shown at room temp., but there is little change in the later slow extension. The influence of alternating temp. is less than that of the maximum temp. of the cycle if a test is made at this high temp. GD (8a)

Precision that endures is a characteristic feature of "ROCKWELL" Hardness Testers

THROUGH eighteen years building of these testers, we know that many of them are used in research and testing for determination of specification limits, where high accuracy is essential, though wear and tear is small. Thousands of our machines have gone into production testing, equally demanding accuracy, but where they are driven continuously and hard. No one has ever had to specify which sort of use one of these testers is purchased for. Every machine is built to meet all requirements, for each is an instrument of *durable accuracy*.

Design-stress Diagrams for Alternating Plus Steady Loads. J. B. KOMMERS (Univ. Wisconsin) *Product Eng.*, Vol. 9, Oct. 1938, pp. 395-397. Review plus new data. Discusses the utility of the Goodman diagram, suggests a new formula and type of diagram for determining safe stresses for parts subjected to alternating plus steady loads, and offers test data and practical applications of the suggested diagram and formula for 3 steels [0.27, 0.37 (sorbitic) and 0.62% C.] The chief objections to the Goodman diagrams are (1) the lack of corroborative evidence, (2) the fact that the endurance ratio of .33 assumed by the Goodman diagram does not agree with frequent experimental observations that the average endurance ratio for wrought ferrous metals is close to .50, and, most important, (3) that part of the diagram lying between the yield point and ultimate tensile strength is useless practically because a cyclic maximum stress in excess of the yield point of a material would never be desirable. A new type of diagram is suggested, from which—in conjunction with certain formulas given in the text and a knowledge of the endurance limit for completely reversed stressing and yield point of the material—the designer can very easily determine endurance limits for various combinations of alternating and mean stresses. In the new diagram, the upper unit of stress is taken as the static yield point; for steels with 2 yield points, the lower is chosen. When the alternating stresses are tension and compression, the tensile yield point is used; for torsional stresses the yield point in torsion is employed. The equations and diagram are recommended for use only when complete information on the various fatigue limits for different values of the ratio of minimum to maximum stress in a cycle is not available. Typical examples of the practical application of the formula are given. [Torsional yield strengths will have different values if determined from tests of solid specimens from values determined from tests, of thin-walled hollow specimens.—H.F.M.] Ha + FPP (8a)

The Tensile Stresses In a Bearing Metal Cast on to a Strip and the "Fatigue" Failure of Bearings. F. C. THOMSON, A. S. KENNEFORD & G. C. SEAGER. *Engineering*, Vol. 146, Aug. 26, 1938, pp. 235-236; Sept. 9, 1938, p. 295. Original research. Deals with a series of measurements on composite bars that provide some idea of the order of stresses in the white metal in bearings. Specimens used were rectangular strips, 0.02 in. thick, 6 in. long and 1 in. wide, on which, after tinning, 0.17 in. of bearing metal was cast. Gives derivation of formula used in calculating tensile strength of white metal. Discusses the variation of the coefficient of expansion of the backing metal, the effect of the thickness of white metal on the contraction stress and temperature effect. Gives results of tests on a special machine designed to superimpose rapidly pulsating compression stress on test piece subjected to tensile stress. Claims that small tension stresses in white metal bearings exert a harmful effect under contant hammering. **The Tensile Stresses in a Bearing Metal Cast on to a Strip and the "Fatigue" Failure of Bearings.** J. DICK. *Ibid.*, Sept. 9, 1938, p. 299. Claims that in the calculations of effect of steel, support of white metal was omitted, and gives method of calculating the formula for estimating maximum stress in bearing metal. VSP (8a)

Preliminary Fatigue Studies on Aluminum Alloy Aircraft Girders, Goodyear-Zeppelin Corp. *Nat. Advisory Comm. for Aeronaut.*, Technical Note No. 637, Feb. 1938, 36 pp. Research. Using a special resonance fatigue machine, aircraft girders mounted with terminal shoes were magnetically vibrated at the natural frequency of the system, thus subjecting the girder section, about 3 ft. long, to alternate tension and compression. Girders of the types used on the Shenandoah, Los Angeles and Macon, and some experimental types, one a spot-welded design, were tested. A small proportion of the girders were run at low enough stress so that failure occurred at about a million cycles, but most of them were more highly loaded. On the whole, with girders of satisfactory design, the endurance curve lay at about ⅓ the stress of the corresponding curve for the heat-treated duralumin-type alloy of which they were made. The one spot-welded girder failed at a load and life far below the scatter band for the others. Rivet-holes, filled with rivets that were well squeezed down, were not as serious stress-raisers as were open holes. Punched and flanged open holes were notable locations of stress concentrations, but this is ascribed chiefly to residual stress or actual cracks from the flanging. The size of a hole in relation to the width of the material around the hole seemed to have an effect. Smaller holes gave better results. Old, unprotected girders that were somewhat corroded appeared somewhat injured in fatigue. Some earlier tests were made from zero to a desired tensile stress. Strict comparisons were not possible, but in general, the results were not widely different whether the stress range was pulsating, from zero to tension, or reversed, from tension to compression. HWG (8a)

The Influence of Previous Repeated Stressing on the Number of Bending Overstresses Withstood and on the Endurance Limit in Bending of "Steel 37" (Der Einfluss einer Wechselvorbeanspruchung auf Biegezeit- und Biegewechselfestigkeit von Stahl St 37) H. MÜLLER-STOCK, E. GEROLD & E. H. SCHULZ. *Arch. Eisenhüttenw.*, Vol. 12, Sept. 1938, pp. 141-148. Original research plus review of prestressing, overstressing and "damage line" in fatigue testing. "Steel 37" is a low C structural steel. A test piece previously stressed for a short time above its endurance limit will endure more reversals at this stress than a previously unstressed piece. If the piece is previously stressed for a longer time, however, its endurance on stressing the second time is decreased. The endurance limit of a test piece damaged by prestressing does not decrease linearly with increased prestressing, but decreases slightly at first and then more rapidly. However, a specimen not too severely damaged by previous overstressing still possesses an endurance limit although this is lower than that of the fresh material. Similar results were obtained with the somewhat harder steel St 52. 10 references. [The above results in general are in harmony with Kommers' results, see *Metals and Alloys*, Vol. 9, Oct. 1938, p. MA 616.—H.F.M.] SE (8a)

Fatigue of Pb and Pb Alloys. K. ONO. *Nippon Kinzoku Gakukai-Si*, Vol. 2, June 1938, pp. 290-295. In Japanese. Original research. The fatigue of Pb was studied under 3 different conditions: Chill-cast, forged (self-annealed), and forged (100° C. annealed). The fatigue strength was the best in the chill-cast state. The influence of gas atmosphere on fatigue was next examined; CO_2 raises the fatigue strength but O_2 lowers it; H_2 apparently has little effect. In wet O_2 the fatigue strength of Pb was found to be greater than in dry O_2. In still water, the fatigue strength was greater than in the air, as the action of O_2 is checked, but it was smaller than in H_2 atmosphere since water acts more or less as a corrosive agent. In the case of running water, fatigue was also greatly retarded because the cooling effect acts more than the corrosive effect of water. [It would be of interest to know the rate of repetition of stress, as this is a vital factor in the case of lead and some other very soft metals.—H. F. M.] NS (8a)

Some Aspects of Failures in Steel. ROBERT HUNTER. *J. West Scot. Iron Steel Inst.*, Vol. 45, Jan. 1938, pp. 41-63. Critical review from mathematical standpoint. Some of the current theories of elastic and fatigue failures of steel are discussed with regard to the derivation of the mathematical relationships. The type of stresses in fatigue failure are analyzed and the empirical and theoretical values compared. 23 references. FGN (8a)

Note on Heat of Self-diffusion (Notiz zur Selbstdiffusionswärme) J. A. M. VAN LIEMPT. *Rec. Trav. Chim.*, Vol. 57, July/Aug. 1938, pp. 891-892. In German. Original research. Demonstrates how the formula for self-diffusion advanced by Cichocki

$$Q = \frac{V}{8\chi}$$

(Q = self-diffusion heat, V = atomic volume, χ = coefficient of compressibility) can be converted into the equation set forth by the author

$$Q = 32\ T_s$$

(T_s = abs. melting point). A table lists values of V, χ and Q for 11 of the most important metals, showing that the Einstein constant is somewhat lower than calculated by him. EF (9)

New Methods for Studying Diffusion in Metals (Nouveaux Procédés pour l'Étude de la Diffusion Métallique) PIERRE CHEVENARD & ALBERT PORTEVIN. *Compt. Rend.*, Vol. 207, July 4, 1938, pp. 71-73. General description. The direct method for determining the rate of diffusion of one metal in another has to do with the change in concentration at a point or a surface as shown by chemical microscopy or spectrography. Indirect methods suitable are as follows: (1) Variation of properties in alloys, compressed powders, or welded layers as diffusion proceeds. (2) Changes in resistivity during diffusion. (3) Changes in the curvature during heating of 2 Fe-Ni alloys, *e.g.* 25 and 36% Ni, as the Ni in the 2 layers becomes diffused. (4) Changes in the Curie point of ferromagnetic alloy as the concentration varies due to diffusion. FHC (9)

A Simple Method for Finding All Possible Solutions of the Problem of Indexing X-ray Powder Spectrograms of Complex Cubic Crystals. V. N. PROTOPOPOV. *Zhur. Eksptl. i Teor. Fiz.*, Vol. 8, Apr. 1938, pp. 498-505. In Russian. Theoretical. Detailed description of a new method for the evaluation of X-ray powder spectrograms of complex cubic systems using geometrical data only. The determination of the indices ($p_1p_2p_3$) does not depend on the presence of "first" lines or the absence of some other lines in the spectrogram. The indices are determined independently of the lattice constant a, and vice versa. In both cases, the solutions are multi-valued. For the selection of the correct solution, additional data are required. The method is illustrated on the X-ray powder spectrogram of pyrite. ORS (9)

Features of Strain Detection by X-rays as Compared to Mechanical Strain Measurement (Die Besonderheiten des Röntgenographischen Spannungsmessverfahrens im Vergleich zur mechanischen Spannungsmessung) H. MÖLLER. *Arch. Eisenhüttenw.*, Vol. 12, July 1938, pp. 27-31. Review of previous work, and new determinations of strain in thick steel plates by means of X-ray crystallograms and by mechanical measurements. By means of the latter an indication of the strains throughout the plate may be obtained, while X-rays give an indication of the strains only near the surface. Se (9)

Thermomagnetic Bi-anisotropy of Crystals. N. S. AKULOV & R. G. ANNAYEV. *Zhur. Eksptl. i Teor. Fiz.*, Vol. 8, Mar. 1938, pp. 334-341. In Russian. Theoretical. A new method for measuring thermomagnetic properties of ferromagnetic crystals is described in detail. The effect of the bi-anisotropy of these crystals on their thermomagnetic properties has been determined. The relation between the thermomagnetic effect and the mutual position of the magnetizing force, temp. gradient and the crystal axes is treated analytically. ORS (9)

Gases in Metals and Their Influence, Adsorption, Absorption and Chemical Reactions. HENRY LEPP. *Metal Ind., London*, Vol. 53, July 8, 1938, pp. 27-30; July 15, 1938, pp. 59-63; July 22, 1938, pp. 79-83; July 29, 1938, pp. 103-107; Aug. 5, 1938, pp. 131-136. Unusually comprehensive review. English version of a paper originally published in *Bull. Assoc. Tech. Fonderie* (see *Metals and Alloys*, Vol. 9, Mar. 1938, p. MA 184R/2). 89 references. RWB (9)

Properties of Interacting Electrons in Metals. V. A. SAVEL'YEV. *Zhur. Eksptl. i Teor. Fiz.*, Vol. 8, Jan. 1938, pp. 13-23. In Russian. Theoretical. Employing the method of configurational space with asymmetrical functions, the effect of the exchange interaction of electrons in a metal on the distribution of the energy levels is analyzed. The results of the mathematical analysis are used in an approximate determination of the relative amounts of the electric and thermal conductivities, as well as of the heat capacity at constant volume, which are due to the interaction of electrons. It is shown that the interaction of electrons contributes to the conductivities, its effect increasing with decreasing temp. ORS (9)

On the Interaction of Atoms in Alloys. WILLIAM SHOCKLEY (Bell Tel. Lab.) *J. Chem. Phys.*, Vol. 6, Sept. 1938, pp. 523-525. Original theoretical research. A generalization of Bethe's theory of superlattices, so as to take into account the interactions between atoms that are not nearest neighbors in the lattice, is considered. This procedure will not furnish any great improvement in agreement between theory and experiment because it predicts, in disagreement with experiment, that many properties of binary alloys are symmetrical between the 2 constituents. It is further shown to be in disagreement with certain fundamental features of the interactions of atoms in alloys. EF (9)

Atomic and Tonic Radii.—I. Numerical Values and Their Bearing on the Compressibilities of Metals. WM. HUME-ROTHERY & G. V. RAYNOR. *Phil. Mag.*, Vol. 26, July 1938, pp. 129-143. **II. Application to the Theory of Solid Solubility in Alloys.** *Ibid.*, pp. 143-152. **III. Polarization Effects in Alloys.** G. V. RAYNOR. *Ibid.*, pp. 152-165. Theoretical review. The compressibilities of elements and alloys as influenced by their atomic radii and interatomic distances, and the various theories on metallic properties based on electronic and atomic theories are discussed exhaustively. 38 references. Electrolytic Determination of Non-metallic Inclusions in Steel (Beitrag zur elektrolytischen Bestimmung von nichtmetallischen Einschlüssen im Stahl) P. KLINGER & W. KOCH. *Arch. Eisenhüttenw.,* Vol. 11, May 1938, pp. 569-582. Critical review and original research. A new electrolytic extraction method is described in which a sodium citrate-potassium bromide-potassium iodide solution is used. The main feature of the procedure is that the separation of the inclusions is performed in a constantly flowing neutral solution continuously replenished by fresh electrolyte. Anodic oxidation is thus avoided. The anode chamber is not restricted by a collodion bag. Under these conditions the oxide residue is not attacked. Carbides and sulphides are first separated from the residue and SiO_2, Al_2O_3, FeO, and MnO are then determined. Analyses were made on 0.01 to 1.2% C steels containing from 0.03 to 1.0% Mn and from 0.01 to 1.0% Si. Concordant results in good agreement with other methods were obtained. SE (9a)

Structure of Gray Cast Iron (Nouvelles Recherches sur la Fonte Grise et la Formation de sa Texture) F. GIRARDET. *Bull. Assoc. Tech. Fonderie,* Vol. 12, Mar./Apr. 1938, pp. 35-45. Research. A method for the study of the macrostructure of cast Fe is described and some conclusions resulting from this study are given. The polished specimen is anodically etched to develop a network structure. The appearance of this structure is associated with the raw materials, the melting method, and the physical properties of the casting. From the macroscopic structure of cast irons, it is concluded that the liquid metal is not a single homogeneous phase, but rather an emulsion or dispersion of several liquid, solid or gaseous phases in the more abundant phase. The liquid metal does not pass from the liquid to the solid state by the formation of crystalline elements, but passes through an intermediate state as an emulsion of liquid droplets. WHS (9a)

The Magnetic Relations in Hardenable Ferritic Iron-nickel-copper Alloys (Ueber das magnetische Verhalten aushärtbarer ferritischer Eisen-Nickel-Kupfer-Legierungen) WALTER DANNÖHL. *Z. Metallkunde,* Vol. 30, Mar. 1938, pp. 95-99. Discussion with original data. According to earlier work (*Metals and Alloys,* Vol. 8, Dec. 1937, p. MA 764 R/10) the magnetic hardness of "irreversible" Fe-Ni alloys is not due to the transformation of residual austenite to martensite by annealing, but rather to the re-formation of austenite. The annealing of Fe-Ni-Cu alloys produces new austenite and a Cu precipitate simultaneously. In an alloy of 12% Ni and 15% Cu, $H_c = 328$ oersteds at $B_r = 3920$ gausses was obtained. Cooling to —182° C. causes decomposition of the austenite formed by annealing and is accompanied by a marked decrease of the coercive force while the magnetic saturation and the remanence increase. GD (9a)

On the Allotropy of Stainless Steels. FREDERICK MARK BECKET (Union Carbide & Carbon Res. Labs.) *Metals Tech.,* Vol. 5, June 1938, 22 pp. An up-to-date review of the significance of structural changes on the properties of steels of the stainless type. Particular attention is paid to the embrittling action of the σ phase in high-Cr alloys, although this phase is not held responsible for the familiar "475° brittleness" in stainless steels. The author questions the widely accepted theory that "intergranular corrosion" of these steels is caused by precipitation of Cr-rich carbides at the grain boundaries, with consequent depletion of Cr in the solvent alloy nearby. He describes this increased corrodibility to internal strain resulting from the $\gamma \rightarrow \alpha$ transformation in the Fe. JLG (9a)

Electric Charges in Solid Solutions (Electrische Ueberführungen in festen Metallegierungen) W. SEITH & TH. DAUR. *Z. Elektrochem.,* Vol. 44, Apr. 1938, pp. 256-260. Original research. Charges of the carbide and boride ions in solid solution with Fe are positive; that of the nitride ion is negative. D.c. was passed through a high-purity Fe wire 1.5 mm. in diameter and 50 cm. long for 3-22 hrs. *in vacuo* at 900°-1100° C. A section 1 cm. long in the middle of the wire contained the element under consideration, in solid solution. Examination of wire on either side of this section after electrolysis showed whether the ion migrated toward the anode or cathode. Prolonged treatment with Ni and Si as solutes gave no results. The Cu-Sb Diagram. III. Transformations in the Solid State. T. MURAKAMI & N. SHIBATA. *Nippon Kinzoku Gakukai-Si,* Vol. 2, Aug. 1938, pp. 365-378. In Japanese. Original research. By means of differential dilatometric and electric resistance measurements and microscopic examination, the β region was further revised, and η and δ redetermined. θ is formed from β, γ and $Cu_{11}Sb_4$ by a peritectoid reaction at 440° C. and 38.95% Cu; β decomposes into θ and δ by the eutectoid reaction at 436° C. and 63.5% Cu. In cooling, although the peritectoid reaction is accompanied by expansion and decrease in electrical resistivity, the eutectoid reaction is accompanied by contraction and increase in electrical resistivity. The solubility range of η at δ peritectoid temperature (462° C.) and the eutectoid composition of the same phase are assigned as 73.5-74.1% Cu and 73.9% Cu, respectively. For previous work, see also *Metals and Alloys,* Vol. 9, Feb. 1938, p. MA 109L/4. NS (9b)

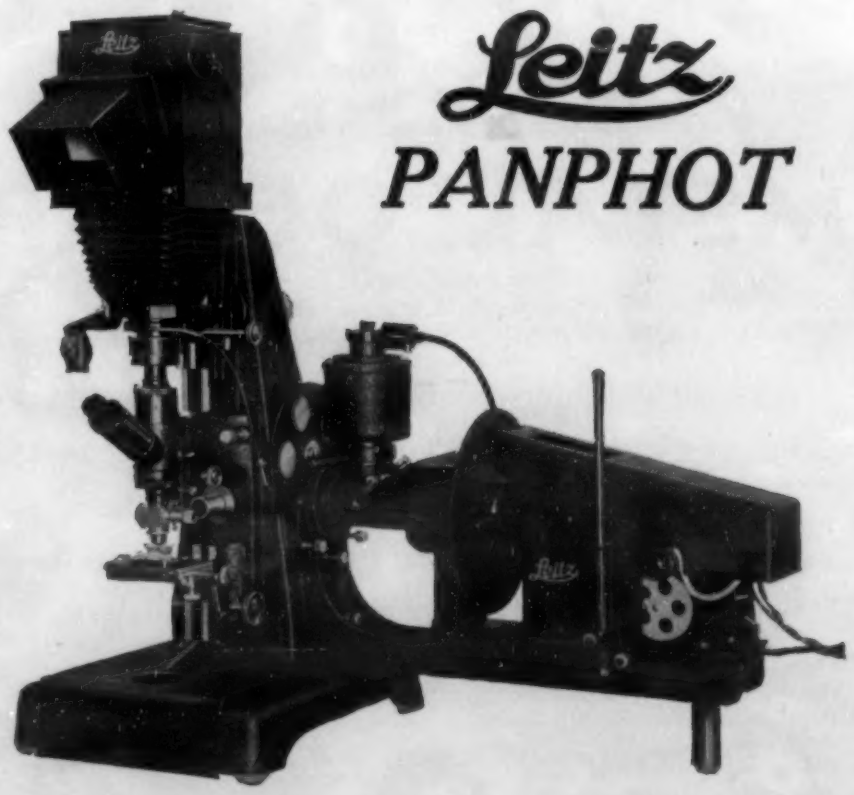
The Constitution of Cu-rich Cu-Si Alloys. T. ISAWA. *Nippon Kinzoku Gakukai-Si,* Vol. 2, Aug. 1938, pp. 400-409. In Japanese. Original research. By X-ray analysis, α solubility limit was determined as 4.99% Si at 800° C. and 3% Si at 300° C. A new phase forms by peritectoid reaction of α and β at about 6% Si and 830° C. The solubility range of the new phase at 780° C. and room temperature are given as 5.8-6.5% Si and 5.8-6.0% Si, respectively. The new phase has close-packed hexagonal lattice with $a = 2.552$ A.U., $c = 4.152$ A.U., $c/a = 1.626$, with 16 atoms or 2 molecules of Cu_7Si in its unit cell. β has body-centered cubic lattice with $a = 2.848$ A.U., and forms an intermediate phase. γ has about 1% solubility change above 600° C. The author would call the new phase "beta", and would call the phase now known as β, "epsilon". NS (9b)

An X-ray Study of Silver-zinc Alloys Rich in Silver, Below the β-transformation Temperature. E. A. OWEN & I. G. EDMUNDS. *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 808, 12 pp. Original research. The phase boundaries of the Ag-Zn system below the temperature of the β transformation were determined by X-ray methods. All the boundaries in this region of the accepted diagram require modification. The β + ζ phase field is found to be very narrow; its lower boundary reaches a minimum value at about 262° C. for an alloy containing about 65% Ag. This temperature is lower than either of the β-transformation temperatures in the adjacent duplex regions. **The Silver-zinc Equilibrium Diagram and the Structure of the ζ Phase.** *Ibid.,* Advance Copy No. 809, 11 pp. Original research. Results of the authors' work published in other papers on the Ag-Zn diagram is used in constructing an accurate Ag-Zn diagram. The ζ phase was investigated by means of X-ray analyses and found to possess a close-packed hexagonal structure with 54 atoms to the unit hexagonal cell. JLG (9b)

The Specific Heats of Beryllium Nitride, Phosphorus Nitride and Titanium Nitride. SHUN-ICHI SATOH. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Aug. 1938, pp. 888-896. In English. Original research. The specific heats of the nitrides of Be, P and Ti, not previously determined, were determined in the ice calorimeter. The following equation of the true specific heat of Be-nitride was established (temp. ranges: 0°-99.5° C., 0°-303.3° C., and 0°-500.3° C.) $C = 0.2726 + 7.884 \times 10^{-4}t - 5.163 \times 10^{-7}t^2$. The determinations on P-nitride at 0°-99.6° C. and 0°-305.3° C. yielded $C = 0.2027 + 6.252 \times 10^{-4}t$. The following equation expresses the true specific heat of Ti-nitride in the temp. ranges of 0°-99.6° C., 0°-305.3° C. and 0°-500.5° C.: $C = 0.14140 + 1.918 \times 10^{-4}t - 1.127 \times 10^{-7}t^2$. EF (9b)

The Distribution of Silicon in Aluminum. YU. A. KLYACHKO. *Zhur. Priklad. Khim.,* Vol. 11, Jan. 1938, pp. 190-191. In Russian. Original research. Preliminary report of results of a new method for determination of the distribution of Si among the different phases (free Si, Al-Si solid solution and SiO_2) in solid technical Al. The amount of SiO_2 was found to be proportional to the amount of Si in solid solution. The presence of SiO_2 in solid Al, despite the fact that SiO_2 and Al react with each other in the metal bath and contrary to thermodynamic reasoning, is explained in terms of the micellar structure of metals and is attributed to the known surface activity of Si in Al. ORS (9b)

Electron Diffraction Effects from Polished Zinc Surfaces. M. L. FULLER (N. J. Zinc Co.) *Metals Tech.,* Vol. 5, Sept. 1938, T. P. No. 965, 11 pp. Original research Under certain circumstances polished surfaces of Zn yield electron-diffraction effects that indicate the surface to be definitely crystalline. These effects are in the form of diffraction lines perpendicular to the shadow edge of the reflection type of photogram. Quantitative correlation was made with the hypothesis that the polished Zn surface consists of very minute crystals of Zn, oriented with their basal planes parallel to the plane of polish. Experimental evidence from the laboratory and from the literature have been adduced to show that the diffuse-halo pattern alone has no significance with respect to composition and crystal structure of a surface, and that whether or not such a diffraction pattern is obtained is dependent on the surface texture of the specimen. No rigorous explanation can be given for the genesis of the haloes. 29 references. JLG (9b)



The Constitution of Lead-rich Alloys of Lead and Cadmium. E. C. ROLLASON & V. B. HYSEL, with an appendix on **The Thermodynamic Analysis of Solutions of Cadmium in Lead.** E. C. ROLLASON. *J. Inst. Metals,* Vol. 63, 1938, Advance Copy 803, 10 pp. Original research. The constitution of Pb-rich Pb-Cd alloys was determined by means of heating and cooling curves, microstructures, and electric resistivity measurements on wires held at elevated temperatures. The eutectic is at 248° C. and 17.5% Cd. Pb dissolves 3.3% Cd at the eutectic temperature, 0.8% at 150° C., and 0.3% at room temperature. Thermodynamical analysis of the data indicate that both the liquid and solid solutions consist of monatomic molecules of Cd and Pb. The molal heat of fusion of Pb is calculated from the data on the diagram to be 5.80 cal./g., which agrees with the value obtained experimentally. JLG (9b)

The Polymorphism of MnSe (Sul Polimorfismo di MnSe) A. BARONI. *Z. Krist,* Vol. 99, July 1938, pp. 336-339. In Italian. Original research. Electron diffraction investigation disclosed 3 types of structure for MnSe similar to those found by Schnaase ZnS structure with a = 5.82 A.U. and tends to transform into the α modification. γ-MnSe is very unstable and crystallizes with a for MnS (*Z. phys. Chemie,* (B) 1933, p. 89). α MnSe has NaCl structure with a = 5.44 A.U. The unstable β MnSe possesses wurtzite structure. The dimensions of the elementary cell are a = 4.12 A.U., c = 6.72 A.U., c/a = 1.63. EF (9b)

The ideal Microscope-Camera Combination for the metallurgist with the following outstanding advantages.

1. Built-in illumination system permanently aligned.
2. Incandescent lamp for visual observation and improved arc-lamp of high and uniform intensity for photomicrography.
3. The object stage of the upright microscope faces the observer who can always see the area of the specimen which is illuminated.
4. The polished surface of the specimen does not rest on the support and the danger of scratching it is completely eliminated.
5. Most convenient transition from visual observation to photography. Ground glass visible from sitting position.
6. From lowest to highest magnifications.
7. All illumination methods can be used: brightfield, darkfield and polarised light.

On the K Phase Adjacent to the Alpha in the Copper-silicon System. M. OKAMOTO. *Sci. Repts. Tohoku Imp. Univ.,* Vol. 27, Sept. 1938, pp. 155-161. In English. Original research. Microscopic and X-ray study was made of certain binary Cu-Si alloys after various heat-treatments. The Si content was varied from 4 to 8%. The existence of the newly discovered K-phase was confirmed, and the limits of its existence were partially defined. Evidence of the K (hexagonal) phase was found from 4.5% to 7.5% Si from the X-ray data. Only K-phase lines were found in the 5.5% alloy. The K-phase seems to be characterized microscopically by a very heavily banded, or twinned-like structure. Various etching agents were used in an effort to find some selective etching agent to differentiate the α and K constituents, but with indifferent success. After quenching alloys ranging from 4.5 to 6.5% Si from 800° C., the structure of the co-existing α and K-phases remained unchanged. The 6% alloy was homogeneous K-phase. The alkaline potassium ferricyanide solution of H. Imai gave as satisfactory an etch for these alloys as anything used. The alloys investigated cannot be considered to have attained equilibrium. AUS (9b)

An X-ray Study of Silver-zinc Alloys Rich in Silver Above the β-transformation Temperature. E. A. OWEN & I. G. EDMUNDS. *J. Inst. Metals,* Vol. 62, 1938, Advance Copy 801, 14 pp. Original research. An account is given of an X-ray examination of the $\alpha - (\alpha + \beta) - \beta - (\beta + \gamma) - \gamma$ boundaries of the Ag-Zn diagram. Results showed that the position of these boundaries as given in the most recently published diagrams need modification. JLG (9b)

The Constitution of the Alloys of Tin with Bismuth. A. C. DAVIDSON. *Tech. Pub. Intern. Tin Research Development Council,* Ser. A. No. 77, Aug. 1938, 14 pp. Review plus original research. Eutectic is 57% Sn at 138.50° C. Solubility of Bi in Sn ranges from over 21% at eutectic temperature to less than 1% at room temperature. Solid solubility of Sn in Bi is between 0.1 and 0.2% Sn at the eutectic temperature. BWG (9b)

Alloys of Mg and Ga, In and Tl (Ueber Legierungen des Mg mit Ga, In und Tl) W. HAUCKE. *Naturwiss.,* Vol. 35, Sept. 2, 1938, pp. 577-578. Original research. Mg and Ga form 4 compounds: Mg_5Ga_2, Mg_2Ga, MgGa and a compound with over 50 atomic % Ga. Mg and In form Mg_5In_2, Mg_2In, MgIn and $MgIn_3$. Only 3 intermetallic compounds are present in the Mg-Tl system: Mg_5Tl_2, Mg_2Tl and MgTl. JZB (9b)

Factors Affecting the Liquidus, Solidus and Solid-solubility Curves in Some Alloys of Magnesium. WILLIAM HUME-ROTHERY & GEOFFREY VINCENT RAYNOR. *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 805, 17 pp. Original research. Factors affecting the solubilities of the B sub-group elements in solid Mg are discussed, with special reference to metals of Group IIIB. The fact that solid Zn and Cd have a smaller tendency to form solid solutions than Mg has is explained on the basis of the modern electron theory of metals. Of the elements of Group IIIB, Ga is outside of the zone of favorable size-factor for Mg, and forms a very restricted solid solution, the maximum solid solubility being 3.14 at. % Ga. Al is on the border line of favorable size-factor, and its solubility in Mg, which is very small at low temperatures, increases to 11.5 at. % at high temperatures, as compared with 19.35 at. % In and 15.4 at. % Tl for the 2 systems where the size-factor is favorable. Relations existing between the liquidus, solidus and solid-solubility curves are discussed. JLG (9b)

The Constitution of the Magnesium-rich Alloys in the Systems Aluminum-magnesium, Gallium-magnesium, Indium-magnesium, and Thallium-magnesium. WILLIAM HUME-ROTHERY & GEOFFREY VINCENT RAYNOR. *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 804, 26 pp. Original research. Equilibrium diagrams for Mg-rich Al-Mg, Ga-Mg, In-Mg and Tl-Mg alloys were determined. Liquidus and solidus curves for the Mg-rich α solid solutions were determined in all 4 systems, and the α solid solubility curve was determined in detail for the alloys with Ga, In and Tl. The liquidus curve for the Al-Mg system is distinctly higher than that of previous diagrams, but agrees well with the values given by Haughton and Payne for ternary Al-Cd-Mg alloys. In the system Tl-Mg, the solid solubility of Tl in Mg is greater at high temperatures and smaller at low temperatures than was previously supposed. The liquidus curve for the more concentrated alloys is higher. JLG (9b)

The Atomic Resistance Increase of Diluted Lead Alloys between 273° and 14° Absolute (Die atomare Widerstandserhöhung verdünner Bleilegierungen zwischen 273 und 14° abs.) A. EUCKEN & H. SCHÜRENBERG. *Ann. Physik,* Ser. 5, Vol. 33, Sept. 1938, pp. 1-20. Determination of numerical values and derivation of formulas for calculation are given. The solubility of Cd, Sb and Mg in Pb was found to be considerably less at room temperature than usually accepted. 20 references. Ha (9b)

Stress-strain Relations under Tension Impact Loading. D. S. CLARK & G. DÄTWYLER (Calif. Inst. Tech.) *Am. Soc. Testing Materials,* Preprint, June 1938, 9 pp. Discusses a method of determining force-elongation diagrams for metals under tension impact loads. A new type of tension dynamometer is described, and results of tests on a few steels and non-ferrous metals and alloys at a velocity of about 11 ft./sec. are given. The reliability of this method has been demonstrated by the agreement shown between the measured and computed values of energy and elongation. The dynamic force-elongation diagrams for several materials were determined and compared with the static diagrams of the same materials. In most of the cases considered, it was found that the yield and maximum forces are higher with dynamic loading than with static loading. There is some indication that the physical properties of cold-worked materials in dynamic tension are superior to those in static tension. These cold-worked materials show considerably more elongation, and in some cases greater reduction in area, when loaded dynamically than when loaded statically. The results obtained with 18-8 Cr-Ni and 17S-T duralumin indicate that these 2 materials may possess very low critical velocities. VVK (10)

Cobalt and Its Alloys (Le Cobalt et ses Alliages) J. CHALLANSONNET. *Tech. Moderne,* Vol. 30, July 15, 1938, pp. 483-489. Comprehensive review. Pure Co is similar to Ni except that its tensile strength is higher (71,000 lbs./in.^{2} compared with 60,000 lbs./in.^{2} for Ni) and its Curie point is 1,150° C. (Ni is 540° C.). Masumoto alloys with 54% Co, 36.5% Fe and 9.5% Cr are corrosion resistant and have a coefficient of expansion 1/12 of that of Invar. Ni-Co alloys are used for magnetic temperature regulators, as the Curie point varies directly with composition. Hastelloy A with 56% Ni, 22% Fe, 19.5% Co and 2.5% Mn is easily worked and used for high corrosion resistance (e.g. against concentrated HCl at 80° C.). Konel with 70% Ni, 19.5% Co, 7.4% Fe and 2.8% Ti is used for elevated temperature strength. Primary use of Co is in high speed steels to increase cutting efficiency. Since 1910 high speed steels with 5-20% Co have been used for special purposes, although decarburization must be carefully guarded against. The heat treatment is somewhat different from that of the usual 18-4-1 and 14-4-2 types in that the austenite is very resistant to tempering, and several temperings are necessary to obtain a thoroughly martensitic matrix. JZB (10)

Rough Compressibilities of Fourteen Substances to 45,000 kg./sq. cm. P. W. BRIDGMAN (Harvard Univ.) *Proc. Am. Acad. Arts Sci.,* Vol. 72, Feb. 1938, pp. 207-225. Original research. The apparatus previously used for measuring transitions at high pressures (*Metals and Alloys,* Vol. 8, Feb. 1937, p. MA 101L/6) has been employed for rough measurements of compressibilities up to 45,000 kg./cm.^{2} (650,000 lbs./in.^{2}). The following elements were tested: Pb, Sn, In, Ba, Sr, Ca, Cs, Rb, Li, Na, K. The experimental results are in fair agreement with theoretical calculations of compressibilities based on wave mechanics. Data obtained are also checked against Murnaghan's formula of elasticity (*Am. J. Math.,* Vol. 59, 1937, p. 235) dealing with relation between stress and strain for finite strain. EF (10)

The Crinkling Strength and the Bending Strength of Round Aircraft Tubing. *Nat'l Advisory Comm. for Aeronaut.,* Report No. 632, 15 pp. A study of the upper limit of column strength or crinkling strength and bending strength of thin walled, round, aircraft tubing of normalized Cr-Mo steel and duralumin, heat treated and cold drawn to a relatively high tensile yield strength. Equations developed from empirical data are also expressed in terms of the specification values. The test procedure was excellent. JBJ (10)

Change of Magnetic Resistance of Pure Metals (Zur magnetischen Widerstandsänderung reiner Metalle) M. KOHLER. *Naturwiss.,* Vol. 35, Sept. 23, 1938, p. 630. Original research. All metals except Bi show a relationship between the change of resistance with temperature and the change of resistance with field strength. JZB (10)

Beryllium and Its Alloys. *Metallurgist (Suppl. Engineer),* Aug. 1938, pp. 148-151. Correlated abstract of 17 references, based chiefly on the recent work of Hessenbruch (*Metallwirtschaft,* Vol. 17, May 20. 1938, p. 541). The production of ductile Be seems no nearer to attainment, and to date about the only possible use for pure Be would be in accoustics applications because of the very great velocity of sound travel through the metals. Be-rich alloys are definitely lacking in ductility. The properties and uses of the 2-4% Be-Cu alloys are well known; the next important development may be the successful commercial production of Be-Cu alloys directly by electrolysis. Attempts have been made, with some success, to produce age-hardening Be-Cu alloys in which most of the Be is replaced by Co or Cr. General Electric's Trodalloy No. 1 (2.6% Co, 0.4% Be) and No. 2 (0.4% Cr, 0.1% Be) are typical of such alloys. Hessenbruch refers to a Be-containing tool steel in which the age-hardening effect of Be is superimposed on the quench hardness of C steel, but no details are yet available. VVK + FPP (10)

Nickel-bearing Alloys Used in Petroleum Refining. B. B. MORTON (Intern. Nickel Co., Inc.) *Refiner Natural Gasoline Mfr.,* Vol. 17, June 1938, pp. 306-312. Review. Ni-bearing alloys are widely used in refineries to meet demands imposed by the wide variations of temperature used (—150 to 2,000°F.) and the presence of organic and mineral corrosive agents. The 2.25% Ni steels meet the requirements for vessels and equipment operating at the sub-zero temperatures used during dewaxing of lubricating oils. Monel, Ni, Inconel, and 18-8 are available for use where very low temperatures are encountered. An austenitic cast Fe is one of the most widely used of the Ni-bearing alloys, and finds application in pumps handling naphtha, reflux, acids and bases. The heat-resisting alloys, containing 25-30% Cr, have their physical and oxidation-resisting qualities enhanced by the presence of Ni; these alloys usually contain 12-25% Ni. VVK (10)

The Effect of Hydrogen on the Properties of Steel (Ueber die Beeinflussung der Stahleigenschaften durch Wasserstoff) A. LEON. *Montan. Rundschau,* Vol. 30, Aug. 16, 1938 (Section *Stahlbau-Technik*) pp. 1-5. Review. H taken up by molten steel has no effect on the C, S and P in the melt; it decreases the O content, and deoxidation of steel with H should therefore be possible. During and immediately after solidification the steel gives off a large part of the H taken up. Hot working accelerates this. However, even forged pieces of steel may hold considerable quantities of H for a long time. During cooling the liberated H may form gaseous compounds with other elements in the steel, such as C, O and S. Hot working of H-containing steel with less than 0.6% C causes brittleness both at white and red heat. This difficulty can be overcome by cooling followed by reheating and hot working. Ni-Cr steels containing H, with 1% Cr and 3% Ni, show brittleness at red heat, but not at white heat, when forged. They also have a tendency to spalling, which is not overcome by annealing for 1 hr. at 1000° C. Impact strength and resistance to aging of unalloyed steels are lowered by H, but the original impact strength is restored by annealing. The Brinell hardness of a steel is also generally lowered by H. BHS (10a)

Trains Run On Chilled Car Wheels. PAT DWYER (Staff) *Foundry,* Vol. 66, Aug. 1938, pp. 22-24, 62; Sept. 1938, pp. 32-33, 68; Oct. 1938, pp. 32-34, 78, 80. Practical. Considers the history of Griffin Wheel Co. and describes the manufacture of chilled car wheels. Advantages of chilled tread wheels are: (1) Hardness of tread, and maximum service; (2) bearing value unexcelled; (3) rotundity is retained, due to absence of ductility; (4) coefficient of friction between wheel and brake shoe is 20% greater than developed by other types of wheels; (5) durability of brake shoes is 25-100% greater when used on chilled tread wheels; (6) abrasion between chilled Fe flange and steel rail is much less than that of steel flange against steel rail; and (7) factor of safety against derailment is greater. VSP (10a)

The Development of High Strength Steels for Large Steel Structures (Die Entwicklung der hochfesten Stähle für den Grossstahlbau) PAUL HOFF. *Mitt. Kohle u. Eisenforsch.*, Vol. 2, Feb. 1938, pp. 1-82. Unusually comprehensive review. The development of these steels is characterized by the increasingly severe requirements that structural steels must meet. At first, to around 1900, the development of structural steels essentially depended on the steelmaking processes. A basic open hearth and Bessemer steel with about 37 kg./mm.^{2} tensile strength found wide application in steel and bridge construction. After the World War, a steel with higher yield point was sought in Germany. Ni and Cr-Ni structural steels proved uneconomical. In 1924 "Steel 48" with higher C content, permitting 30% higher loads than "Steel 37," was marketed; in 1925 a Si structural steel followed. The development of the high quality structural steels such as "Steel 52," within the last decade is described as a special accomplishment of German metallurgy. The consuming industry has had much to do with this rapid development, particularly the German State Railways. A comparison with the progress of these structural steels in the most important industrial countries is made to show the leading role of Germany in this field. of low alloy high strength structural steels. The yield point is the decisive property of statically loaded structural parts. By using structural steels with high yield point, it is possible to allow higher loads and save weight. The possibilities of weight and cost savings have been further increased by greater application of welding. In many respects the knowledge of the effect of different alloying constituents on the practical behavior of a structure is farther advanced than that of the value of certain mechanical properties and methods of testing. Recently a basic change in methods of evaluating tensile properties has occurred, in that the stress distribution in structures, and testing under actual service conditions are increasingly emphasized. Further progress should be directed toward unification and standardization of composition. A steel economical in use, *i.e.* a steel of high durability will be preferred. The foreign countries followed the German development only partially. Some countries, such as France, adapted the German "Steel 52," while new structural steels of high tensile strength were developed in England and U.S.A. These steels are stated to possess poor welding properties. Recently in Britain and America the development of structural steels of high yield point and good weldability has also been carried on. 240 references. GN (10a)

The Structure and Mechanical Properties of High Test Cast Iron (Ueber Gefügeausbildung und Festigkeitseigenschaften hochwertiger Gusseisensorten) P. BARDENHEUER & W. BRÖHL. *Mitt-Kaiser-Wilhelm-Inst. Eisenforsch., Düsseldorf*, Vol. 20, No. 11, 1938, pp. 135-146. Original research. The relations between structure and mechanical properties of low-C cast Fe types was investigated on melts of different compositions. Decreasing C and Si content induced a more favorable graphite formation and improved the mechanical properties. A very low C content produced a form of graphite similar to temper carbon. Increase of Mn increased tensile strength in sand castings up to 1.2% Mn in untreated and up to 1.4% Mn in heat-treated samples; further increase in Mn reduced the tensile strength. The tensile strength of chill-mold cast samples decreased, however, with increasing Mn. Brinell hardness increased in all heat-treated samples with increasing Mn content, but decreased in un-heat-treated samples beyond 1.2% Mn. Repeated impact strength showed a maximum at 1.4% Mn. High Si and Mn content (4.8 and 4.5% resp.) with different C contents reduced tensile strength considerably, irrespective of heat-treatment and casting method, while hardness and brittleness increased, except melts with low C which showed good mechanical properties. Solidification of an inoculant-free melt produced the pseudoeutectic with its unfavorable effect on mechanical properties. Inoculation of a low C melt with soda and carbon produced a structure of pearlite and temper carbon, but had less or no effect with high C content. Temper carbon is the most favorable form of graphite for mechanical properties; it is produced in all white chill-mold castings by subsequent heat-treatment, and in sandcastings only for C contents below 2%. Annealing is of advantage for medium-C contents while for low-C quenching in oil with subsequent annealing at high temperature is advisable. 18 references. Ha (10a)

Centrifugally Cast Bushings (Schleudergussbüchsen) W. A. GEISLER & H. JUNGBLUTH. *Tech. Mitt. Krupp. Tech. Ber.*, Vol. 6, Aug. 1938, pp. 96-101. General review of present wear-resistant materials and methods of manufacturing them for linings of cylinders and bushings with and without water-cooling. Ordinary cast Fe or Fe with a few tenths of 1% Cr of very fine grain and a Brinell hardness of at least 260 is being produced by centrifugal casting. Martensitic bushings are heated to 850° C., quenched in oil and drawn; their hardness is 400-500 Brinell. Alloy cast Fe with up to 0.5% Cr and about 1% Mo is used for Diesel engines. Cast Fe with 1% Cr and 1% Al is particularly suitable for nitrided bushings, giving 700-900 Vickers on the surface. 13 references. Ha (10a)

Effect of Arsenic on the Properties of Steel and Cast Iron (Einfluss des Arsens auf die Eigenschaften von Stahl und Gusseisen) F. KÖRBER & G. HAUPT. *Arch. Eisenhüttenw.*, Vol. 12, Aug. 1938, pp. 81-89. Review. In steel static tensile tests
1 indicate As up to 0.3% is not injurious. The tensile strength, with up to 2% As increases, then decreases. Hardness is little affected by up to 0.8% As. The impact properties are lowered. Stead reported the bend properties of steel with up to 1% As
— to be satisfactory, but others found them to be lowered by 0.2% As. Some found about 0.25% As to injure the hot rolling properties, while others noted no such effect up to 4% As. Arsenic injures high speed steel. Above 0.1%, As impairs weldability.
2 As improves corrosion resistance. It improves transformer steel by lowering the Watt loss. In cast Fe, As lowers the tensile strength, increases the hardness, lowers the transverse bending strength when above 1% As is present, particularly when the P and S are high. Up to 0.3% As the wear resistance is improved
— —beyond that it is injured. As improves corrosion resistance against both acids and alkalies. 51 references. SE (10a)

Effect of Arsenic on the Properties of Steel (Einfluss des Arsens auf die Stahleigenschaften) E. HOUDREMONT, H. BENNEK, H. NEUMEISTER. *Arch. Eisenhüttenw.*, Vol. 12, Aug. 1938, pp.
3 91-101. Original research. Up to 1% As was added to a series of C, Cr-Ni, and Cr-Mo steel melts made in a 25 kg. induction furnace. Up to 0.25% As was also added in the ladle of full size basic Bessemer and O. H. steel melts. Pipe and blowholes in the
— ingot were not affected by As. Arsenic segregates about the same as P in effervescing steel and C, P, and S in killed steel. The hot working properties were unaffected by As up to 1%. Arsenic in general raised the tensile properties and lowered the toughness,
4 particularly in harder steels. No injurious effect of As on cold deformability was noted. Up to 0.25% As did not injure the weldability of sheet steel. Above that the weldability of gas welds was seriously injured. The tensile strength of gas and electric
— welds of sheet with up to 0.25% As was not lowered. Arsenic injured forge welding more than it did electric welding. Up to 0.2% As did not lower the hardness of tool steel; above that it did. The temperature of the α-γ transformation is raised by As.
5 The toughness of harder heat-treated steels is appreciably lowered by even small amounts of As. If As were to be used as an addition element, it would gradually build up in the scrap, as Cu and Ni do. SE (10a)

The Exceptional Wearing Properties of Early Steel Rails. C. J. ALLEN. *Iron & Coal Trades Rev.*, Vol. 137, Sept. 23, 1938, pp. 467-468; Sept. 30, 1938, pp. 507-508. The fact that steel
— rails made in the earliest days of steel making were superior, and sometimes in use for 40 years, is commented upon. They were
6 made of acid Bessemer steel of 0.32-0.45% C, 0.2 and, in other years, 0.056-0.093% Si, 0.71-1.14% Mn, 0.05-0.072% P and 0.075-0.122% S; they were rolled and finished at lower temperatures than is practical now. Brinell tests on the running surfaces showed
— much greater hardness than on web and foot, showing that the surface had hardened considerably under traffic. In spite of different C contents, the hardness of the running surface in 5 rails was the same, showing that the low C rails had greater capacity
7 to harden than those with higher C; this is ascribed to work-hardening rather than age- or skin-hardening. In the long years of service the rails were hardened and therefore can withstand modern railroad service. This fact might account for the less satis-
— factory behavior of modern steel rails, although made under much more uniform and exacting conditions, as they are at once subject to heavy traffic and can not gradually "age" under lighter traffic conditions. The change of British standards for rails is compared
8 from 1909 to 1935. The average composition now required is 0.55-0.61% C, 0.125-0.132% Si, 0.70-1.05% Mn, 0.04% P and 0.038-0.05% S, with a breaking strength of 52 ton/in.^{2}, elongation 13.5-18% and a reduction of area of 17-29%. Present manufacturing conditions and testing methods are described. Ha (10a)

Cast Crank- and Camshafts (Gegossene Kurbel- und Nockenwellen) H. JUNGBLUTH. *Tech. Mitt. Krupp, Tech. Ber.*, Vol. 6,
— Aug. 1938, pp. 88-96. Review. The good practical behavior of cast crankshafts and cams is believed due to the embedded graphite, which reduces the elasticity modulus and notch-sensitivity and in-
9 creases damping properties. Comparisons with steel and malleable Fe are made, and present methods of manufacturing and the changes of structure by local hardening are described. Crankshafts are cast of pearlitic, sometimes slightly alloyed Fe, heat treated martensitic cast Fe, or of a material similar to malleable Fe.
Ha (10a)

— **The Properties and Uses of Chilled Iron.** S. C. MASSARI (Assoc. of Manufacturers of Chilled Car Wheels) *Am. Soc. Testing Materials*, Preprint, June 1938, 16 pp. Review. This paper describes the basic metallurgy of chilled Fe, its technique of pro-
10 duction and metallographic nature. Recent developments in the heat treatment of chilled Fe with the subsequent improvement in physical properties and metallographic structure are described. The effect of alloying elements in increasing or decreasing depth of chill is discussed. VVK (10a)

Change of the Modulus of Elasticity and Damping of an Iron-nickel Alloy at the γ-α Transformation (Aenderung von Elastizitätsmodul und Dämpfung einer Eisen-Nickel-Legierung bei der γ-α Umwandlung) E. SCHEIL & W. THIELE. *Arch. Eisenhüttenw.*, Vol. 12, Aug. 1938, pp. 103-105. Original research. The apparatus for determining the modulus of elasticity and damping properties of a thin wire about 150 mm. long is described. The alloy used contained 22.4% Ni, the γ-α transformation occurring at about 135° C. The wire is oscillated in torsion and as it is cooled through the γ-α transformation the vibrations are rapidly damped. The modulus of elasticity also falls sharply during the transformation. SE (10a) 1

Some Autarchic Trends with Respect to Steels (Alcuni indirizzi autarchici nel campo degli acciai) T. NATALE. *Ind. meccanica*, Vol. 20, Aug. 1938, pp. 663-666. In order to be independent (from the Italian economic standpoint) of foreign metals, an examination was made as to how far Ni in steels can be replaced by W or other elements without impairing, in any way, their mechanical properties. A list of alloy steels commonly used at present in Italy, with their properties, is given. For stamping and other dies, a series of steels with 4.4% Cr and varying amounts of 6-25% W, 0-4% Mo and 1-2.5% V are recommended. Ha (10a) 2 3

Characteristic Values of High-grade Cast-iron (Gütewerte von hochwertigem Grauguss) K. KNEHANS. *Tech. Mitt. Krupp, Tech. Ber.*, Vol. 6, Aug. 1938, pp. 102-108. Results of tests of mechanical properties for some German standard cast irons are described. Tensile strengths of 34,000-64,000 lbs./in.², bending strengths of 78,000-91,000 lbs./in.² with 13-15 mm. deflection, Brinell hardness of 220-250, and tensile strength of 18,000-23,000 lbs./in.² at 600° C. Bending-fatigue and impact tests were also made. Ha (10a) 4

Pilger Mill Mandrels Not Containing Imported Alloying Elements. I. ROZENBLIT. *Stal*, Vol. 8, Jan. 1938, pp. 52-59. In Russian. Practical. A study of steels containing neither Ni nor Mo, which Russia must import, showed that steel containing 0.29% C, 0.95% Mn, 0.94% Si and 1.0% Cr was superior in service to the steel previously used which contained 0.35-0.55% C, 0.4-0.7% Mn, 0.20-0.45% Si, 0.4-0.8% Cr, 1.3-2.2% Ni and 0.2-0.4% Mo. Recent Progress in the Field of Rolled Aluminum Alloys (Ueber einige neuere Fortschritte auf dem Gebiete der Aluminium-Walzlegierungen) P. BRENNER. *Aluminium*, Vol. 20, Sept. 1938, pp. 606-620. Review. The production of Al ingots that are sounder and contain fewer gas inclusions, is made possible by the Züblin method, which uses a mold, with a vertical slit, through which the liquid metal flows in a channel. The method is claimed to reduce the possibility of liquid jets carrying along impurities and absorbing gases; segregations are avoided. An Al-Cu-Mg block showed a much more uniform Cu distribution and finer grain; the differences in Cu content at different places were not greater than 0.7%. These ingots are good enough to be used directly for rolling or forging without first remelting the ingot. Experiments with Al-Mg alloys have shown that these alloys are still inferior to Al-Cu-Mg with regard to intercrystalline corrosion, and that, particularly for airplane parts, the danger of harmful precipitation due to temperature differences is present. Diagrams show the influence of heat-treatment on the corrosion resistance, and microphotographs show the structural changes. 15 references. Ha (10b) 7 8 9

The Tensile Properties of a Series of White-metal Bearing Alloys at Elevated Temperatures. H. GREENWOOD. *Tech. Pub. Intern. Tin Research Development Council*, Ser. A., No. 58, Aug. 1938. Original research. Tensile properties of typical Sn-base bearing alloys were examined at temperatures up to 175° C., and the effects of Cd and Pb additions were noted. As the temperature rises, maximum stress and yield fall fairly uniformly, while elongation and area reduction increase. Cd markedly increases tensile strength when cold but helps little when the alloys are hot, *e.g.* addition of 1% Cd increases tensile strength 50% at room temperature but only 10% at 175° C. Addition of 4% Pb may be slightly beneficial when cold but decreases the tensile strength at elevated temperatures. BWG (10b) 10

OFHC

OXYGEN FREE HIGH CONDUCTIVITY

A Superior Copper

FOR ALL PURPOSES

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Silver Membranes. HAROLD J. READ & MARTIN KILPATRICK (Univ. Penn.) *Trans. Electrochem. Soc.*, Vol. 74, 1938, Preprint No. 17, 23 pp. Original research. The Ag membranes were prepared by heating a thin sheet of Zn-Ag alloy (0.013 cm. thick) in a vacuum (0.2 mm. of Hg) at a temperature 650-850° C. for 2-20 hours. Practically all the Zn distilled out of the alloy, leaving behind a porous sheet of Ag. The permeability of the Ag was determined by measuring the rate of diffusion of gases through a thin sheet of the material. The membranes were more permeable to gases of low molecular weight. Erratic results were obtained with easily condensable gases, such as CO_2 or water vapor. A number of factors influenced the permeability of the membranes. A Ag-Zn alloy containing 13% Zn did not yield a membrane permeable to gases, but an alloy containing over 20% Zn was satisfactory. The Zn content could not be increased above 28.5% because the resulting alloy was too brittle to roll into the thin sheets required for the preparation of membranes. An increase in the time or the temperature of heating increased the permeability, and an increase in thickness of sheet decreased the permeability of the membrane. Subjecting the alloy to a sudden heating produced a membrane with a higher porosity than by gradually raising to temperature. Photomicrographs of the membranes were studied but yielded no relation between surface appearance and permeability. By calculation, the average radius of the pores was found to be 10^{-4} cm. and the average number of pores per cm.² was several thousand. AB (10b)

Alloys with Low Copper Content (Les Alliages à Faible Teneur en Cuivre) L. GUILLET. *Cuivre et Laiton*, Vol. 11, Sept. 30, 1938, pp. 415-416. Review. Antifriction metals, Zn alloys and Al alloys with less than 15% Cu are discussed and their importance explained. Cu_3Sn forms distinct microscopic needles and is used, as is $CuAl_2$ (with 12% Cu), for bearing bushings. The most-used Zn alloy is 92% Zn, 3% Cu, and 4% Al; it has a tensile strength of 50,000 lbs./in.² and elongation of 1-5%. It should be cast in chill molds to avoid a transformation that takes place with slight contraction. The Zn used should be very pure, and the addition of 0.05% Mg effects stabilization in 4-5 weeks. The various known binary Al alloys with Cu, duralumin and alloy V, are briefly described. An addition of Ti facilitates thermal treatment and produces fine grain. The Al alloy with 4.5% Cu, 0.5% Ti is treated by heating for 5 hr. at 525° C. and "tempering" for 9 hr. at 150°; it has a tensile strength of 43,000 lbs./in.² and an elongation of 5%. Ha (10b)

Non-ferrous Metals in Shipbuilding. Reciprocating, Turbine and Oil Engine Construction. J. W. DONALDSON. *Metal Ind., London,* Vol. 53, Aug. 26, 1938, pp. 195-198; Sept. 2, 1938, pp. 231-233. Review. Recent developments in marine engines require better materials of construction. Although steel is used principally, the range of non-ferrous alloys has been greatly extended. Marine engineering uses non-ferrous alloys principally for their corrosion resistant properties, although recently Al alloys have found application because of the weight saving. Casting alloys include gunmetal, P-bronze, brass, Cu-Ni, Al, and bearing alloys. Wrought alloys of Cu, brass and Cu-Ni are used chiefly in the form of tubes, sheets, and bars. Admiralty gunmetal of 88% Cu, 10% Sn and 2% Zn is in common use. When exposed to steam the Sn must not exceed 10%, but for simple air pressure 12% Sn alloy is used. Hard bearings require an alloy of 82% Cu and 18% Sn. Where salt water conditions do not require hardness, a 93% Cu, 4% Sn, 2% Zn and 1% Pb alloy is used. For withstanding severe corrosion Monel or Ni bronze is used. Cast Al alloys consist essentially of Al and Si. White metal, Cu-Pb, Cd-Ni and Pb-base bearing alloys have recently found considerable application. Cu-Ag-Zn alloys are finding limited application in turbines. Boiler construction is principally ferrous. In maritime reciprocating engines and auxiliaries, non-ferrous alloys are chiefly used for bearings. Monel, stainless steel and alloy steels have replaced 70/30 brass, P-bronze and Cu-Mn for turbine blading. Gunmetal is used for numerous parts and fitting of turbines. Non-ferrous alloys find considerable application in marine oil engines in bearing fittings, pistons, starters, cooling systems, air compressors, etc. Corrosion is one of the most serious problems in marine engineering, and is a special problem in condenser tubes. It has been established that the best protection is afforded by means of strong adherent films, either self forming or artificial. Alloys of 70/30 Cu-Ni and Al brass possess film forming properties and have almost entirely replaced other alloys for this purpose. Boiler and steam line valves have spindles of rolled naval or high tensile brass and seats of Admiralty gunmetal. In turbine work Monel metal or Ni-bronze seats are used with naval or high tensile brass or alloy steel spindles. Horizontal or vertical centrifugal pumps and reciprocating pumps use considerable gunmetal, special brasses, Cu-Ni alloys and bearing metals. In small craft and fast motor boats, shafting of steel has been replaced by non-ferrous alloys. Propellers use special high tensile brass. See also *Metals and Alloys,* Vol. 9, July 1938, p. MA 454R/2. RWB (10b)

The Effect of Cold-work and Annealing on the Hardness of Some Sn-Sb, Sn-Sb-Cu and Sn-Sb-Ag Alloys. R. E. LEYMAN. *Tech. Pub. Intern. Tin Research Development Council,* Ser. A, No. 53, June 1937. Original research. Mechanical properties of pewter were studied by hardness tests on Sn-base alloys containing 3-7% Sb with or without addition of 0.5-3% Cu or Ag. All alloys at first hardened on slight or moderate cold rolling, but after 20-40% area reduction progressive softening occurred, until a hardness equal or less than that as cast was reached after about 80% cold reduction. Softening on severe working was most pronounced with highest percentage of alloying elements. Annealing after rolling caused further softening in most cases but the alloys containing 3% Cu or 0.5-3% Ag recovered part of the hardness lost on severe working. Quenching-aging treatments were without permanent effect although the Sn-Sb-Ag alloys showed an appreciable hardness increase on quenching, which was lost in 100 days at room temperature, or more rapidly at higher temperatures. BWG (10b)

The Properties of High Purity Aluminum. C. S. TAYLOR, L. A. WILLEY, DANA W. SMITH & JUNIUS D. EDWARDS (Aluminum Res. Lab.) *Metals and Alloys,* Vol. 9, Aug. 1938, pp. 189-192. Reports original work on the physical constants of Al of 99.996% purity. The methods for the various determinations are given and the following results were obtained for certain properties: Melting point, 660.24° C. Thermal expansion $L_t = L_o [1 + (23.22t + 0.00467t^2 + 0.0000078t^3) 10^{-6}]$ where L_t is length at temperature t and L_o is length at 0° C. Lattice parameter a = 4.0415 A.U. Density at 20° C., 2.6953 gm./cc. (calculated from lattice parameter). Density (hydrostatic weighing) at 20° C., 2.6989 gm./cc. Volume resistivity in microhms-cm. at 20° C. → 2.6548. Volume percent conductivity (Internat. annealed Cu = 100%), 64.94%. Mass resistivity in ohms (meter, gram) at 20° C., 0.07165. Mass per cent conductivity (Cu = 100%) → 213.92%. Mechanical properties and radiation characteristics are also reported. WLC (10b)

Mechanical Properties of Some White Bearing Metals and Other Tin-base Alloys at Various Temperatures. C. S. HORNER & H. PLUMMER. *Tech. Pub. Intern. Tin Research Development Council,* Ser. A, No. 57, Aug. 1937. Original research. Tensile and hardness tests were made at various temperatures on a series of typical Sn-base bearing metals, with and without the addition of varying amounts of Cd. Strength and hardness increased with additions of up to 3% Cd. Strength increases with over 3% Cd were offset by loss of ductility. The extra strength due to Cd was retained at elevated temperatures, although all alloys lost strength with temperature increase. Elimination of Sb showed no advantages and many disadvantages. Strength values were strongly influenced by rate of strain; this rate could be increased with temperature increase, but at any given temperature a critical speed of testing could be found that would give maximum strength values. BWG (10b)

The Effect of Iron on Magnesium. W. R. D. JONES. *Metallurgist* (*Suppl. Engineer*) Aug. 1938, pp. 157-158. Original research. Molten Mg will not dissolve Fe to any appreciable extent. Fe-Mg alloys up to 0.24% Fe were made by melting Fe sawings mixed with Mg sawings in a thick-walled capsule of Mg metal that was placed in the molten Mg. Flux used was magnesium chloride mixed with magnesium fluoride. Table gives mechanical properties of alloys. In the cast state, physical properties are improved somewhat by small amounts of Fe, but with more than 0.14% the values are diminished. Fe decreases the values for the mechanical properties of rolled bars of Mg. Effect of small amounts of Fe on Mg is not disadvantageous. Fe does not decrease the physical properties until present to an amount definitely much in excess of that which Mg or its alloys can pick up during normal melting operations. VVK (10b)

Fusible Alloys Containing Tin. E. J. DANIELS. *Tech. Pub. Intern. Tin Research Development Council,* Ser. B, No. 5, Aug. 1937, 24 pp. Comprehensive description. The relation of composition to melting point, structure and physical properties of fusible metals is described. It is important to cast the alloys under controlled conditions to get dependable results in regard to plasticity and creep. Many of these alloys expand on solidifying. Methods of avoiding corrosion troubles are given. Applications include sprinkler plugs, boiler plugs, fusible links, seals for glass apparatus, patterns for molding and electroplating, tube bending, for tempering baths and die mounting. 117 references. Investigations on Magnetically Oriented Bismuth (Untersuchungen an magnetisch orientiertem Wismut) A. ALTMA. *Ann. Physik,* Series 5, Vol. 32, July 1938, pp. 489-506. Research. If Bi powder is allowed to fall through a magnetic field, the particles orient themselves with the principal crystallographic axis in the direction of the magnetic field. Such powder column can be compressed to a briquette that then behaves like a single crystal in the magnetic field and shows the characteristic anisotropy of the Bi crystal structure. Results of measurements of physical properties are given. Ha (10b)

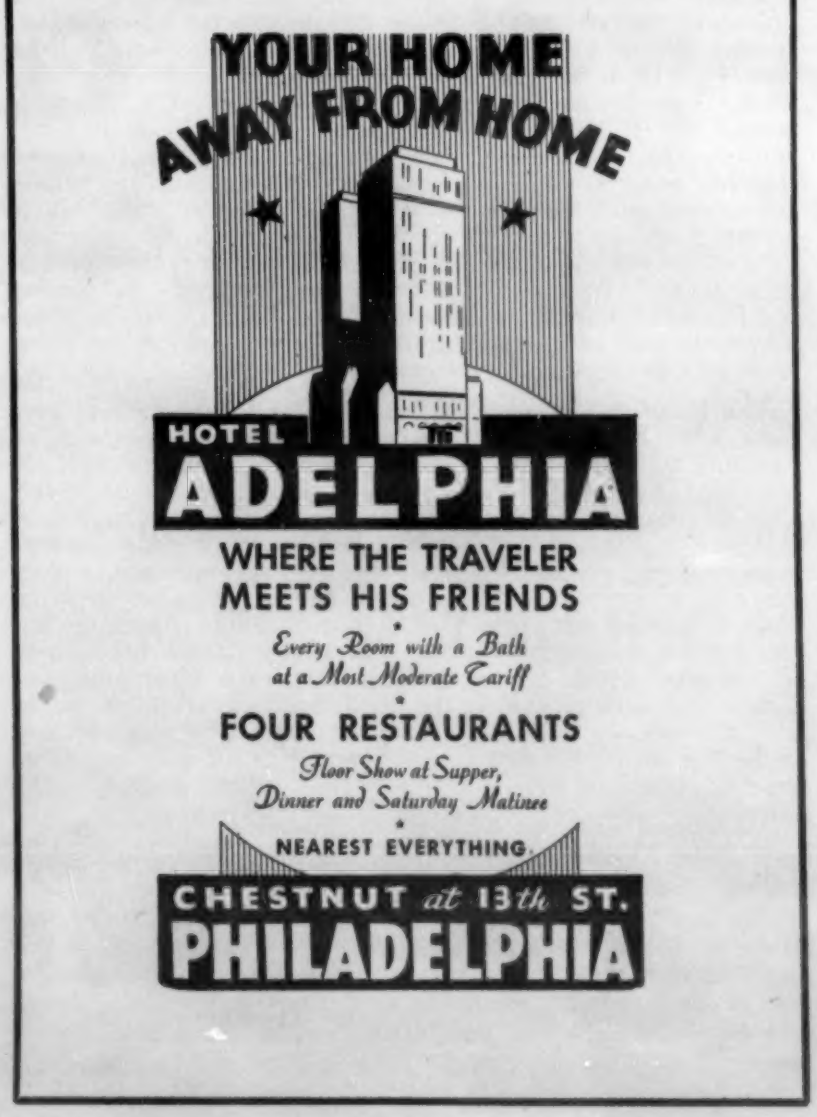
New and Growing Uses for Aluminum. J. O. CHESLEY (Aluminum Co. of America) *Mining and Met.,* Vol. 19, Oct. 1938, pp. 431-435. Practical discussion of the application of Al. VSP (10b)

10c. Effect of Temperature

H. C. CROSS, SECTION EDITOR



The abstracts in this section are prepared in cooperation of the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Report of Joint Research Committee on Effect of Temperature on the Properties of Metals. *Am. Soc. Testing Materials, Preprint,* June 1938, 70 pp. Progress report with data as reported in the following papers: **Progress Report on Creep Tests of Tubular Members Subjected to Internal Pressure.** F. H. NORTON. 3 pp. Some data reported but are not as yet complete. Tests are on C-Mo steel at 800 and 1050° F. and on 5 Cr, 0.5 Mo steel at 1200° F. However, it is interesting to note that under certain conditions a pressure vessel may decrease in length during service and under other conditions may increase in length substantially at the same rate as the diameter increases. **Report on Long-time Creep Test of 0.35 Per Cent Carbon Steel (K20).** HOWARD C. CROSS & J. S. LOWTHER. 8 pp. The long-time creep test on this annealed 0.35% C steel at 850° F. indicates extrapolation from the 2000 hr. period to be conservative, as compared with the actual deformation measured over 20,000 hr. An approximately constant rate of deformation was obtained between about 4000 and 20,342 hr. Experiments on effect of temperature on the creep rate while

loaded to 7500 lb./sq. in. indicate a change of creep rate of 5-1 for temperature change 50° F. below or above 850° F. Tensile and impact tests on the specimen 25B5 after creep test indicate very small and unimportant changes in physical properties to have occurred due to the time at temperature under load. Examination of the structure indicates little or no change from that shown for the material as heat treated and before creep test. This very stable structure no doubt accounts for the long period of constant creep rate and unchanged physical properties. **Report Covering Creep Tests on 0.35 Per Cent Carbon Steel (K20) at 850° F. Under Stress of 7500 Lb. Per Sq. In.** C. L. CLARK. 10 pp. The data submitted permit the following conclusions: The K20 steel used was of at least as high a degree of uniformity as it is possible to secure commercially under the present knowledge of melting practice and the results obtained from the tests at 850° F. are in very good agreement when the comparisons are based on creep strength. The relative strengths range from 1.00 to 1.074. The agreement in creep strength is of the same order of magnitude as that found to exist previously in the elevated temperature tensile strength values. If the same results are compared on the basis of creep rate rather than creep strength, then appreciable differences do exist which cannot be directly related to the type of equipment used, the size of specimen, the type of extensometer, the temperature uniformity of the specimen or to the electrical characteristics of the furnace. The results, therefore, indicate that the creep rate and deformation characteristics are too sensitive an index of strength to permit exact duplication either in different laboratories or in duplicate tests in the same laboratory. The results obtained from certain of the tests at temperatures other than 850° F. are not in as good agreement either among themselves or with the results obtained from the 850° F. tests. These apparent discrepancies may be due either to slight non-uniformities in the steel or to as yet unknown inconsistencies in the testing technique. **Report on Acceptability Tests for High Temperature Characteristics.** A. E. WHITE & C. L. CLARK. 5 pp. The stress-rupture test consists of fracturing a series of specimens at each temperature under fixed loads so adjusted that the resulting fracture times vary from a few minutes up to 15 hrs. When the stresses and corresponding fracture times are plotted to logarithmic coordinates, a straight-line relationship exists, provided the material possesses a sufficient degree of structural and surface stability under the given test conditions. It is thus possible to obtain the stresses corresponding to definite fracture times. Data are reported for K20 (.35% C) steel, SAE 1040, .5% Mo steel and 4-6% Cr-Mo steel. **Progress Report on Study of Effects of Manufacturing Variables on the Creep Resistance of Steels.** H. C. CROSS & J. G. LOWTHER. 23 pp. This progress report shows results of creep tests at 850° F. on 12 plain C steels with known Al additions and one C-V steel. Some of the steels were tested at 750° and 950° F. Several steels were intentionally coarsened by proper heat treatments to provide material for comparison of the relative creep resistance of fine-grained and coarse-grained materials. The data indicate decided superiority of creep resistance at 750°, 850° and 950° F. for coarse-grained plain C steel over fine-grained plain C steel of the same chemical composition. Several relaxation tests on K20 also indicate superiority for coarsened K20 steel. The C-V steel, which showed superior creep resistance to plain C steel as fine-grained, was not improved greatly by coarsening. **Report Covering Information on Steels for Tubular Creep Tests and Other Test Work of the Joint Committee.** H. J. KERR, J. B. ROMER & H. D. NEWELL. 9 pp. Manufacturing data and micrographs of structure. **Proposed Revised Tentative Method of Test for Long-time (Creep) High-temperature Tension Tests of Metallic Materials.** 6 pp. Specification issued 1935, revised, 1937, 1938. VVK (10c)

Actual Grain Size Related to Creep Strength of Steels at Elevated Temperatures. S. H. WEAVER (Gen. Elec. Co.) *Am. Soc. Testing Materials,* Preprint, June 1938. 6 pp. Original research. A collection of 32 creep tests, all made at the same temperature of 840° F. and all on the same analysis within the commercial limits of S.A.E. 4330, a Ni-Cr-Mo steel, whose creep stresses (for a constant creep rate of 1% per 100,000 hr.) vary from 10,800 to 40,200 lbs./sq. in., was analyzed statistically. Correlation of the creep strength with the actual size of the existing carbide grain (using only those steels with uniform microstructure) showed that there was an optimum grain size for the maximum creep strength; a larger or smaller grain than the optimum value gave a decreasing creep strength. For this particular steel and temperature: (a) Changing the grain size can vary the creep strength by 21,000 lb./sq. in. (b) The structure within the grain can change the creep strength by 4500 lb./sq. in. (c) Ferritic banding in the visible mechanical form can lower the creep strength up to 4300 lbs./sq. in., while in the "masked" or distributed form the effect of banding is negligible. [The method of determination of the grain size is questionable. The paper does not contain sufficient proof of the decreasing creep strength with grain sizes larger than No. 6.—H.C.C.] VVK (10c)

Steels for Use in the Petroleum Industry (Stähle für Treibstoffgewinnungsanlagen) F. K. NAUMANN. *Tech. Mitt. Krupp, Tech. Ber.*, Vol. 6, Aug. 1938, pp. 77-87. Comprehensive research. The behavior of ordinary and alloy steels in cracking and hydrogenization processes at high temperatures and pressures up to 1000 atm., especially in contact with H_2 and H_2S was experimentally investigated. Unalloyed steels with various C contents are attacked by H even at 360° C. at 300 atm. after 300 hr. Increasing pressure shifts the beginning of attack to lower temperatures. Ni steels have scarcely better resistance against H_2; the attack begins also at 350°-400°. Cr-Ni steels show a better behavior if C is low. Cr increases resistance to H_2 attack, especially for Cr contents higher than 3%; this is ascribed to the existence of the carbide Cr_7C_3. Cr-Ni steels with higher C (0.25 and more) are less resistant, since the carbide $(FeCr)_3C$ is present. All high Cr and Cr-Ni steels show excellent H_2 resistance, even with high C content; a steel of 13.6% Cr and 0.35% C, and another of 16.6% Cr and 0.90% C, were still good at 600° C. Austenitic Cr-Ni alloys withstood 750° C. without fracture after 300 hr. W and Mo steels have even better resistance than Cr steels. Steels with 3-6% Cr also possess high resistance to H_2S. V-steels are resistant to H_2 only if the ratio V : C is at least 5.7 : 1, for below this ratio not only the resistant V_4C_3 occurs but also Fe_3C, which is easily attacked. Similarly, in Ti steels, about 4 times as much Ti as C must be present to be resistant to H_2. Neither V nor Ti steels are resistant to H_2S and furthermore are not easily forged in large masses. 10 references. Ha (11)

Recent Investigations on the Atmospheric Corrosion of Iron (Neue Untersuchungen über die atmosphärische Korrosion des Eisens) W. H. J. VERNON. *Korrosion u. Metallschutz*, Vol. 14, June/July 1938, pp. 213-220. Review of the author's previous work. Experiments with commercial Fe of about 0.1% C in normal and saturated atmospheres, some pure and some inoculated with the usual air-borne particles, are described in detail. Curves show the progress of loss of weight of the samples in the various atmospheres and the effect of CO, CO_2 and SO_2. CO_2 has in general a retarding effect on corrosion, even if SO_2 is present with CO_2; after 100 days the loss with CO_2 was only 50% of that without CO_2. Foreign particles in air always hasten the starting and increase the attack of corrosion, especially if specifically active substances such as ammonium sulphate or other dissociated inorganic salts are present. 7 references. Ha (11)

The Rate of Corrosion of Steel in Rural Atmospheres over Long Time Periods (Die Rostungsgeschwindigkeit von Stahl an Landluft im Verlauf sehr langer Zeiten) K. DAEVES & K. F. MEWES. *Stahl u. Eisen*, Vol. 58, Aug. 4, 1938, pp. 841-842. Original research. Rails of 0.25-0.40% C Bessemer steel with 0.15% P and 0.2-0.3% Cu, which had been in service about 27 years and were exposed to the weather 60 yrs., were used to study the rate of corrosion. The average rate of corrosion over the 60-yr. period for these rails was 20-40 g./m.²/yr. During the last year the rate was only 2-3 g./m.²/yr. This indicated that the rate of corrosion keeps decreasing with time even after prolonged periods. This helps explain the good resistance of old Fe. The rate of wear was also determined, this being very small because of the low loads; the coarse microstructure of the rails seemed to favor a low rate of wear. SE (11)

Behavior of Light-metal Alloys in Contact with Moist Acetylene (Das Verhalten von Leichtmetall-Legierungen gegen feuchtes Acetylen) H. LICHTENBERG. *Aluminium*, Vol. 20, July 1938, pp. 465-466. Original research. Al of 99.5% purity and Al alloys, with different surface treatments, were exposed for 300 days to acetylene in an acetylene generator. Except for discoloration in some samples, no change of the surfaces could be noted. The loss in weight was very small; in the worst case it corresponded to a reduction of thickness of less than 0.13 mm. per year. Tests are described in detail. Ha (11)

Atmospheric Corrosion of Non-ferrous Metals and Alloys. Report of the Subcommittee VI of A.S.T.M. Committee B-3 on Corrosion of Non-ferrous Metals and Alloys. W. H. FINKELDEY. *Am. Soc. Testing Materials*, Preprint, June 1938, 23 pp. This report is the third (6-yr.) series of tests made on 24 non-ferrous metals and alloys exposed in 1931 to various atmospheres at 9 test locations. No conclusions are drawn, but the following observations are made: Substantial losses in tensile strength or percentage elongation, or both, have occurred at most of the industrial and sea coast locations for the 3 samples of Zn, commercial Al, some Al alloys, Mn-bronze, 70-30 brass and Sn. With the exception of the 70-30 brass and Mn-bronze, the losses of tensile properties of the coppers and other Cu alloys at all test locations are so small as to be of little significance at this time. The same is true for Ni and the high Ni-Cu alloys, as well as Pb and the Pb-Sb alloy. In the rural locations the losses of tensile properties are negligible for all materials except Sn. Loss in tensile properties has apparently had no relation to change in weight on uncleaned specimens, irrespective of the type of atmosphere, the character of the corrosive attack or the kind of metal or alloy. This is to be expected in the case of those metals subject to serious pitting, an intercrystalline type of corrosion, alloys susceptible to dezincification, or where corrosion products are particularly adherent. Tables of data are given. For previous work, see also *Metals and Alloys*, Vol. 7, May 1936, p. MA 262R/7. VVK (11)

Comparative Corrosion Tests with Commercial Wrought Iron and Low Alloy Steel in Seawater and in the Laboratory (Vergleichende Korrosionsprüfungen mit handelsüblichem Flusseisen und niedrig legiertem Stahl im Meer und im Laboratorium) A. PORTEVIN & E. HERZOG. *Korrosion u. Metallschutz*, Vol. 14, June/July 1938, pp. 205-213. Original research. The tests were made with a salt spray in the laboratory and by immersion in the ocean. Although in general a qualitative agreement for the average velocity of corrosion (as loss of weight) was found the laboratory tests did not exactly agree and showed less loss of weight than in the seawater. A steel with 3% Cr + Al showed a 1/8 to 1/3 lower weight loss in seawater than in the laboratory test. The corrosive attack depends to a large degree on surface condition. 7 references. Ha (11)

Boiler Feedwater Studies, Report of Joint Research Committee. C. H. FELLOWS. *Am. Soc. Testing Materials*, Preprint, June 1938, 3 pp. Progress report. Laboratory work indicates that lignins successfully prevent the development of intercrystalline cracking in steel specimens stressed under a static load or in a reversed torsional load. Work planned includes study of the effects of chlorides on embrittlement, further work on lignin and concentration of boiler water salines in capillary spaces of boilers, study of tendency of actual boiler water to cause embrittlement and a study of the occurrence or possibilities of occurrence of caustic embrittlement in boilers operating above 500-lb. pressure. VVK (11)

The Parabolic Law of Oxidation. G. D. PRESTON. *Phil. Mag.*, Vol. 25, July 1938, pp. 65-82. Theoretical discussion. The law as expressed by $w^2 = 2kt$, where w is the weight of O combined on unit area of the metal surface after time t (initial weight being zero), and k is a parameter, is discussed theoretically with regard to practical applications. The parameter k is not a constant but must be considered as proportional to pressure. This would explain an increase of oxidation as calculated from the law, and also observed to hold for metals under stress, which oxidize more rapidly than those in an unstressed state. Ha (11)

The Prospects of Aluminum as Corrosion Protection of Iron (Die Aussichten des Aluminiums für den Korrosionsschutz des Eisens) *Tech. Blätter*, Vol. 28, May 1, 1938, p. 262. See *Metals and Alloys*, Vol. 9, Oct. 1938, p. MA 612L/7. It is pointed out that Al may well be used in dairies if the necessary precautions such as cleaning by non-alkaline solutions and application of special cooling agents are observed. Numerous investigations have shown that Al and its alloys are stable against almost all dairy products. GN (11)

Corrosion of Steels Containing Tin. *Metallurgist* (*Suppl. Engineer*) Aug. 1938, pp. 151-152. Correlated abstract of 5 references. The existence of Sn as a constituent of steel scrap makes a knowledge of its influence on the properties of steel of vital importance. Work done many years ago showed that over 0.06% Sn impaired the ductility of rail steel, but that in steels of lower-C content, a tendency to red-shortness when Sn exceeded 0.15% was the only noticeable ill effect. Shock resistance of mild steel is reduced by over 0.2% Sn. Recently Daeves has studied the effect of Sn on the corrosion of steels. Careful analysis of his experiments shows that Sn has no deleterious effect on resistance to atmospheric corrosion, but such benefit as it could confer may be obtained with Cu, without the tendency to red-shortness and lowered ductility associated with Sn. This applies equally to steels with and without Cu. VVK + FPP (11)

The Resistance of Metals to Hydrochloric Acid (Einiges über die Beständigkeit metallischer Werkstoffe gegenüber Chlorwasserstoff) E. RABALD. *Chem. Fabrik,* Vol. 11, June 8, 1938, pp. 293-299. Review. An examination of the resistance of elements and commercial alloys to HCl and its salts. Corrosion resistance, strength and fabrication properties of Ag, Pb, Cu, Sb, Ni and Fe alloys in aqueous HCl solutions are given. The effects of HCl in the gaseous state and in the liquid state, as pure HCl or as non-aqueous solutions or aqueous solutions with corrosion promoting or inhibiting additions, are also considered. PCR (11)

Causes, Consequences and Prevention of Corrosion of Mine Pumps (Korrosionserscheinungen an Bergwerkspumpen. Ursachen, Folgen und Beseitigung) *Tech. Blätter,* Vol. 28, May 22, 1938, pp. 301-303. Discusses corrosion due to acidic water, plugging of pipe lines; as corrosion resistant material for the races a synthetic resin product was used. Use of a special acid resistant bronze for various important pump parts, and application of steel pipes coated with bitumen are described. GN (11)

The Corrosion-time Relationship for Underground Pipes: A Theory. NORMAN L. HOFF (Southern Calif. Gas Co.) *Gas Age,* Vol. 81, May 12, 1938, pp. 35-36, 66, 68. After reviewing the various equations that have been proposed for the corrosion-time relationship in soils, the author finds that his study of some 4,000 pit depth measurements on bare steel and wrought Fe pipes of various ages in Southern Calif. soils supports the log-log type of equation. VVK (11)

AMERICAN Radials have an enviable reputation for long productive life and precision performance. Engineers of the American Tool Works Company, builders of American Radials, specify Ampco Metal for elevating nuts, because only Ampco Metal provides the qualities of wear resistance and long life required to protect the vital elevating mechanism of these tools.

Ampco Metal is the invariable choice of machine tool builders for extreme service parts where resistance to wear and maintained accuracy are essential.

AMPCO METAL INC.

General Metallurgical Engineering, Powder Metallurgy, Economics, History, etc.

E. F. CONE, SECTION EDITOR

Powder Metallurgy. Commercial Production of Metal Forms. CHARLES HARDY & C. W. BALKE. *Metal Ind., London,* Vol. 53, Aug. 19, 1938, pp. 171-174. Detailed description of modern methods of production of metal forms from metal powders and the characteristics of the product. This method alone has made possible the production of refractory metals in useful form. (W, Mo, Ta.) The entire development in the field of refractory metals and their carbides in the form of cemented material has made the practice of this art a necessity. The composition of alloys can be consistently reproduced with a uniformity unapproachable by foundry methods. Impurities introduced by conventional methods are reduced or eliminated. Aggregates or mixtures can be made of metals which are immiscible in the liquid state or which have widely divergent melting points. (Pb-Cu, Cu-Mo.) The method makes it possible to produce metals in which a non-metal is uniformly disseminated (Cu-graphite, Cu-Sn-graphite). Those practiced in the art have found that the type of die, type of powder, length of time of heat treatment and temperature of sintering can be so controlled that contraction or distortion can be held within very narrow limits. An accuracy of .001 in. is readily obtainable for a number of alloys. Losses of material in normal methods of casting, etc. frequently reduce the weight of the final product to one-half that of the material used. With such losses eliminated by powder methods, finished products may be produced on a competitive basis. Special structural effects can be obtained by powder methods that are not possible by melting processes, and useful bimetals can be made. The high pressure required in most cases to form the material establishes a definite limitation to the application of the process. Many powders cling to the dies and cause uneven pressure, thus limiting the depth of the dies. Difficulty is encountered from oxidation and controlling particle size of the powder. Al, Sb, Bi, brass, bronze, Cd, Cr, Co, Cb, Cu, Au, Fe, Pb, Mn, Mo, Ni, Pd, Si, Ag, Ta, Te, Sn, Ti, W, V, Zn and practically all metal phosphides can be obtained in powder form. Ag-coated Mo and Cu and Cu-coated Ag and Pb powders are available. Metal powders can be produced by various methods determined by the chemical characteristics of the metal. The results obtained are dependent on the purity of the powder used. In the case of any given application of powder metallurgy most of the following properties must be taken into account and held under control: Particle size, particle size range, apparent density, flow factor, shape of particle, cohesive ability, chemical purity and oxide content. Except in cases of mixed lots and different mesh size of powder, pure metal powder does not require mixing. Powders are usually mixed in tumbler or ball mills. They are usually pressed at room temperature. Except where done simultaneously with the pressing operation, the pressed pieces are given an appropriate heat treatment. No fixed rule can be laid down as to the temperature to be employed in the treatment of alloys. In general the temperature used is about ⅔ the melting point of the alloy. With pure refractory metals, which are heated by passing current through the pressed bars, the temperature at the core is brought very close to the melting point. Where porosity is desired, powdered volatile salts are mixed in the metal powder and when heated volatilize, leaving the space they occupied as pores. RWB (12)

Developments in the Iron and Steel Industry During 1937. W. H. BURR. *Iron Steel Engr.,* Vol. 15, Jan. 1938, pp. 46-53. Descriptive. Some details of construction and operation are given for a high pressure steam turbine driven blower and a new type of molten metal transfer car of 125 long tons capacity. Combustion control has received attention, chiefly in regard to the mixing of 2 or more fuels. This entails proper metering and regulation of the fuels, together with proper regulation of the amount of combustion air required. Two new processes of charging open-hearth furnaces are mentioned. In one, the entire cold charge is added at one time by employing a furnace with a removable front and a special charging machine. The second method makes use of top-charging, with large-capacity drop bottom boxes. Special ingot heating furnaces have been developed which permit very accurate control of temp. One of these is of the rotary type and is self-emptying. Photo-electric cells are used for temp. control in a new forging heater. An outstanding type of heater is one which actually rolls long "sucker bars" through the furnace chamber, delivering them normalized and absolutely straight. Developments in recuperators include a type which makes it possible to clean out the spaces between tubes during operation and one which successfully utilizes straight blast furnace gas for soaking pit heating. Strip mill developments have been quite marked, particular emphasis being applied to speed. A special uncoiler for hot rolled strip permits uncoiling at a high rate of speed without coil breaks. Bearing and lubrication improvements include improvements in oil-sleeve, ball- and non-metallic bearings, lubrication systems and the lubricants themselves. Outstanding in the shearing field has been the development of automatic equipment which makes possible speeds of 400-500 feet per min. with absolute accuracy as to cuts. REB (12)

Alloys of Silver and Iron. COLIN G. FINK & V. S. DE MARCHI (Columbia Univ.) *Trans. Electrochem, Soc.,* Vol. 74, 1938, Preprint No. 25, 10 pp. Original research. Ag-Fe alloys were prepared by powder metallurgy. Fe powder and fine Ag crystals were mixed and compressed into a bar by a pressure of 41 tons/in.^{2} The bar was sintered in a H atmosphere, then cold rolled, and heat treated several times. The following evidence was obtained that a Ag-Fe solid solution containing 0.5-1.0% Ag is formed: (1) Microscopic examination of a Ag-rich alloy showed deeply stained ferrite grains that were attributed to a solution of Ag in Fe. (2) Measurements of the resistivity of the alloys showed that the maximum resistivity (13.17 microhms/cm.^{3}) was exhibited by an alloy containing 0.5-1.0% of Ag. (3) The corrosion of the alloys was measured in 10% HCl and in 30% acetic acid. The alloy containing about 1.0% Ag was the least corroded. AB (12)

The Copper Industry in the Soviet Union (Koppar industrien i socialistiska sovjetrepublikernas union) *Tek. Tid.,* Vol. 68, Sept. 10, 1938 (Section *Bergsvetenskap*) pp. 73-76. Largest Cu deposits in the Soviet are in Kazakstan, the most important of which are the Kounrad and Balkasch deposits. About 4/5 of the production, however, is still coming from the older mines in the Urals. Production in 1936 was about 100,000 metric tons of Cu, with an estimated 130,000 in 1937. During the last years the industry has been widely mechanized, and flotation methods have been generally introduced. Electrolytic Cu is produced at Pishmin refinery, with annual capacity of about 100,000 tons. The anode slimes are treated for Au and Ag in the Kyshtim plant. BHS (12)

News from the Patent Literature (Neues aus dem Patentschrifttum) E. HERRMANN. *Aluminium,* Vol. 20, Sept. 1938, pp. 621-630. Review. Recent improvements in melting processes, alloying of Al-Mg, bearing metals with 3-5% Pb, 3-8% Ca, 3-5% Sb, or Si, Mg and Mn added to Al, casting methods, die-casting, welding, extruding, degreasing and mechanical plating (cladding) are described as reflected in patent literature. A new feature is the replacement of Pb by pure (99.5) Al (or even higher purity) for cable sheaths; the material is made plastic by annealing at 350° C., when it has a tensile strength of 7,800 to 8,500 lbs./in.^{2} and an elongation of 40-55%. 33 references. Ha (12)

Radium. Sources of Production—Treatment of Minerals (Le Radium. Source de Production—Traitement des Minerais) E. PROST. *Rev. Universelle Mines,* Vol. 14, Oct. 1938, pp. 741-751. Exhaustive survey. The various deposits of Ra in the Belgian Congo, Canada and Czechoslovakia (Joachimstal), besides the less important ones in U. S. A. and Madagascar, are described. Properties, chemical composition, methods of extraction, and geological conditions are discussed, and production statistics added. The present price is about $50,000 per g. Ra. 11 references. Ha (12)

Electrochemical Power. Editorial Staff, *Chem. & Met. Eng.,* Vol. 45, Sept. 1938, pp. 462-471. Summary of the Federal Power Commission's comprehensive report on the "Power Requirements in Electrochemical, Electrometallurgical and Allied Industries". Among possibilities in the Pacific Northwest are mentioned Al production from foreign ore and electric production of Fe and steel. Tables give a forecast of consumption of electrical energy per year for some metallurgical industries, as well as electrical energy requirements per short ton. PRK (12)

Free Service Department

Replies to box numbers should be addressed care of METALS AND ALLOYS, *330 West 42nd Street, New York.*

POSITION WANTED: Electrical and metallurgical engineer, M.S., 32 years. Broad experience: ferro-alloys, electric arc and induction furnaces, automatic regulation, layout and maintenance; metallurgical processes. Excellent references, location immaterial. Box MA-108.

POSITION WANTED: Contact man or salesman. Ten years' experience. Both sheet and strip mill. Well acquainted in Cleveland and Detroit districts but location not essential. Age 30. Married. Available thirty days' notice. Box MA-111.

POSITION WANTED: Sales Engineer, age 35, 12 years' selling pumps, valves, pipe, tanks, kettles, castings, and special productions made of metals to resist corrosion, to chemical and industrial plants in large Eastern cities. Capable engineer with knowledge of chemistry and chemical processes. Box MA-109.

WANTED: Combustion Engineer with sound engineering education and practical experience in steel industry including the application of automatic combustion control to furnaces for heat treatment of steel and to open hearth furnaces. Candidates preferred who have made broad studies in accomplishing fuel economies. Work will include creative projects in developing the use of instruments and automatic control equipment. Write describing education and outlining experience as preliminary to personal interviews. Box MA-110.

WANTED: Superintendent for nickel chrome alloy foundry. Must be qualified for complete charge of production of heat and corrosion resisting castings. Box MA-112.

WANTED: Melter for nickel chrome alloy foundry. Must have full knowledge of Moore Lectromelt furnace. Box MA-113.

POSITION WANTED: Detroit representative. Engineer with more than twenty years' experience in selling and manufacturing desires connection with manufacturer who is interested in obtaining representation in Detroit district. Well qualified to handle materials, heat treating equipment and machinery. Box MA-114.

POSITION WANTED: Spectroscopist—15 months' laboratory experience assisting in development of rapid, accurate quantitative methods for spectrographic analysis of iron and steel. Age 22. M.S. in physics. Box MA-115.

POSITION WANTED: Electric Steel Melter. Technical training, 20 years' melting experience, acid and basic practice, castings or ingots, chemical laboratory experience. Able to take charge of melting department. Box MA-116.

POSITION WANTED: Young industrial furnace and combustion engineer, graduate in industrial heat engineering from Carnegie Institute of Technology, and with five years' experience on diversified furnace problems, seeks position in design or sales service field. Philadelphia area preferred. Box MA-117.

. . . the Book everybody is talking about

CORROSION RESISTANCE OF METALS and ALLOYS

A. C. S. MONOGRAPH NO. 71

By. R. J. McKay and Robert Worthington

of service to all who have to do with metals

The thought and data of modern corrosion knowledge have been consolidated under one plan and in one easily understandable unit, making accurate comparison between different metals and between different corrosion conditions possible. A concise outline of the theory of corrosion is included as well as data from test and experience on modern corrosion problems.
This book fills in the gap between modern works on the corrosion of individual metals on the one hand and on specific theories of corrosion on the other, and summarizes the vital points of such treatise.

12 photographs **$7.00**

PHOTOELEMENTS and Their Application

By Dr. Bruno Lange
Formerly Research Physicist with Kaiser Wilhelm Institute
Translated by Ancel St. John, Ph.D.

Dr. Lange is the inventor of one of the most widely used types of photoelectric equipment. He has spent a lifetime studying the subject. And, in this book, he gives a clear outline of the basic phenomena and the historical development of photoelements, their physical properties, and a detailed discussion of the many-sided possibilities of applying them to industrial and scientific uses. The photoelement has tremendous practical utility. Its value is already appreciated in hundreds of technical and scientific fields. Every day new uses are found to which this versatile mechanical sentry can be profitably put. Never sleeping, never winking, always on the job, the "Electric Eye" counts, records, measures, weighs, proportions, opens and closes, turns on and off, inspects for quality and quantity, assures exact printing registry, protects against burglary and tampering.

books

Methods of Mechanical Testing of Metals at Elevated Temperatures *(In Russian)*

A. M. Borzdika

Ferrous Metallurgy Publication Office, Moscow, 1938. Paper, 6 x 9 in., 192 pages. Price 4 rubles.

The book is divided into two parts. The first part presents a general discussion of different methods of heating specimens, measuring and regulating temperature, and measuring deformation. The second, which describes different methods of testing at elevated temperatures, consists of six chapters, of which the first and second relate to the ordinary tensile strength and creep tests, and the others to descriptions of the torsion, impact, fatigue and hardness methods of testing.

The author believes that testing machines having less than ten tons loading capacity should be employed in the tensile test. In his opinion, the universal testing machine designed by Prince Gagarin (known in Russia as "Gagarin's Press") presents many advantages, as compared with other testing machines. [This machine was constructed in Russia by Prince Gagarin around 1900. —A. I. K.]

In Gagarin's machine an almost perfect automatic record of the load-deformation diagram may be obtained. Each millimeter of the abscissa on that diagram is equivalent to 0.01 mm. deformation. In emphasizing the great importance of the time factor in the tensile test, the author gives a table showing the results obtained by him with lead and nickel-chromium steel, the duration of load application until the moment of break being varied in tests:

Material	Temperature Deg. C.	Duration of Test to Breaking Point	Tensile Strength lbs./in.²
Lead	25	1 min.	3,450
	25	10 min.	2,910
	25	60 min.	2,440
	25	180 min.	2,200
Steel containing 0.5% C, 13% Ni, 15% Cr, 2.2% W	600	3-5 min.	81,000
	700	3-5 min.	72,500
	800	3-5 min.	62,500
	900	3-5 min.	35,500
	600	15-20 min.	74,000
	700	15-20 min.	57,000
	800	15-20 min.	32,500
	900	15-20 min.	18,500

In the discussion of the creep test it is mentioned that in one of the creep test laboratories in Russia, four creep torsion testing machines have been installed.

In general, this book may be considered as a text book for students and contains little information new to engineers.—A. I. KRYNITSKY.

The Protection of Ferrous Metals by Phosphate Treatments *(La protezione fosfatica dei metalli ferrosi)*

O. Macchia

O. Lavagnolo, Torino, 1938. Paper, 6¾ x 9½ in., 424 pages. Price 35 lire.

To the urge to substitute protected steel for more expensive non-ferrous metals in Italy, this useful monograph can be ascribed. Some use has been made of phosphate coatings in Italy since 1929, but the rapid methods in which the coating is applied electrolytically or by spraying have not yet been adopted there.

This book seeks to do missionary work, especially in setting forth the suitability of the coatings as primers for some varnish-like types of top coat. It seeks also to replace commercial propaganda by discussing the processes in terms of chemical compounds and the variables involved rather than in trade names. Of some 400 references, only about a score relate to the chemistry of phosphate coatings in a fundamental manner. Prominent among the fundamental publications are several of recent date in Russian, whose meat is given. Since Italian is more intelligible to the average English speaking engineer than Russian, this is a valuable feature of the book.

The historical development of the processes is discussed, primarily in terms of the patent literature. The bath compositions, the effects of the manganese or zinc, of nitrate additions, and of impurities in the phosphoric acid, the methods of cleaning the surface so it will best take the coating, the effect of composition and structure of the steel, chemical control of bath composition, etc., are discussed in detail, often by means of tables or curves, with the behavior of the coating under salt spray or some similar break-down tests as the criterion. The book doubtless gives the fullest published description of the variables involved in the production of satisfactory phosphate coatings. Coating defects are discussed with illustrations and explanations of their causes.

Commercial methods of, and equipment for, application of the coatings are described and pictured, most of the information relating to immersion for quite long periods in solutions heated nearly to boiling. The information on the more rapid methods is less complete and is drawn chiefly from Westinghouse and Ford practice.

Over 75 pages are devoted to the annotated bibliography. The paper used is not very good so that many of the photographic illustrations do not do justice to their originals, though one can generally make out what they are intended to convey. While the contents are equally well written and form as valuable a reference work on this subject as Macchia's previous book on chromium plating, the book making is not up to the standard of that volume. —H. W. GILLETT.

Pewter—Spun, Wrought and Cast

Burl N. Osburn & Gordon O. Wilber

International Textbook Co., Scranton, 1938. Cloth, 7¾ x 10¾ in., 151 pages. Price $2.50.

The authors are instructors at state normal schools or teachers' colleges. Many of the pewter articles illustrated were made by their students. Very detailed instructions are given on how to hammer, spin or otherwise shape pewter and how to cast and solder it. The book is a combination of manual training and of art appreciation in which simplicity and functional utility are stressed as true beauty in contrast to ornamentation for ornamentation's sake alone.

Pewter is so easy to work and has such a pleasing appearance that it is an ideal material for the dual purpose of training the hand to form and the eye to appreciate. One can imagine a man, woman, or child taking great pleasure in making his own

gadgets from pewter in idle hours, much as the sailor does scrimshaw.

There is little metallurgy in the book, though one who works up the alloy as directed will gain quite an understanding of the fundamentals of casting and working. The history of pewter is dealt with interestingly, and the fact brought out that in Colonial days most of the articles and dishes now made in china, silver plate, etc., were of pewter.

After the putterer (we almost said pewterer) has made the objects described by Osburn and Wilber, he will want to try his hand at making other things in the style shown in Bulletin 3 of the International Tin Research and Development Council, "Contemporary Pewter in the Netherlands."—H. W. GILLETT.

Dental Materials

John S. Shell

C. V. Mosby Co., St. Louis, 1938. Cloth, 6 x 9 in., 413 pages. Price $4.50.

This new text is to some extent a revision of *Practical Dental Metallurgy* by Hodgen, but the revision has been extensive and much new material has been included. Likewise, much material on process metallurgy and chemistry has been eliminated. This new publication has been designed to meet the specifications set up by the "Report of the Curriculum Survey Committee of the American Association of Dental Schools" which gave as the objective "To understand the sources, composition and properties of all materials used."

The scope can be indicated by the chapter titles: Characteristics of Metals, Theory of Alloys, Metallography, Low Fusing Base Metals, High Fusing Base Metals, Noble Metals, Gold, Mechanical Properties of Metals, Gold Alloys Used in Dentistry, Base Metal Substitutes for Gold in Dentistry, Heat Treatment of Dental Alloys, Chemical and Electrochemical Reactions of Dental Alloys, Amalgams, Dental Castings, Pyrometry, Refractory Materials, Heating Equipment, Dental Porcelain, Dental Cements, Vulcanized Rubber Dentures, Synthetic Plastics, and Organic Technique Materials.

This arrangement gives about 80% of the volume to metallic materials and related subjects and this distribution might not be approved by all colleges. The order in which the various subjects are presented may not meet with entire approval by all teachers. For example, Chapter 12 presents the heat treatment of dental alloys while pyrometry comes later in Chapter 16 and heating equipment still later in Chapter 18. Gold alloys used in dentistry are covered in Chapter 10, but dental castings are presented in Chapter 15. This arrangement is not serious, however, because the individual teacher can select his own order of presenting the subjects.

The author has taken a forward step in introducing good chapters on the theory of alloys and metallography. Presented from a fundamental point of view, they should be of value to students in dentistry and might be read to advantage also by some of the practicing dentists who want to know more about the materials they are using.

The scheme used in giving the properties of metals and alloys and then showing their uses in dentistry seems to be a good one.

Dental students are more interested in materials if they can be convinced that such information will be of value in their contemplated profession. In some respects the text may tend toward the research or testing point of view too much for the average student. However, more information along these lines and a broader viewpoint should be valuable.

The author has presented quite an extensive treatment of the various subjects and has brought the information up to date. Besides the text there are extensive references to original literature at the end of each chapter. The author has also drawn upon his own researches for data and presents some original information. The writing style is generally easy to read and the publishers have done a good job, with one exception, *i.e.*, the photomicrographs are not good in many cases. That, however, is common in American publications where the same paper is used as that for the printed text. The index is excellent and makes it very convenient to find information; the illustrations also add to the value of this publication.

The book is of decided metallurgical interest, and should be used by teachers and students in dental alloys, by practicing dentists and by manufacturers of the various materials.—OSCAR E. HARDER.

Digest of Properties, Carbon and Alloy Steel Tubing for High Temperature, High Pressure Service.

Babcock & Wilcox Tube Co., Beaver Falls, Pa., 1938. 8½ x 11 in., 76 pages.

This new edition contains added information on the high-temperature properties of the various gradations of compositions of B & W tube steels, from plain carbon to 25 per cent Cr/20 per cent Ni. Especial attention is given to a steel of 2¼ per cent Cr/1 per cent Mo whose creep resistance over the range 900-1200 deg. F. is outstanding among pearlitic steels.

An especially interesting section relates to creep testing practice of Professor Norton at M.I.T., where 3,000-hr. tests are standard, and a special furnace, controlled within ±0.2 deg. F. is used with a 10-in. test length to determine the creep rate to the nearest 0.1 per cent in 100,000 hr.

The effects of alloying elements on high-temperature properties are concisely discussed. The pamphlet is of interest to a much wider group than the users of tubing. It bears evidence of preparation by metallurgical experts rather than by those who prepare most commercial booklets.—H. W. GILLETT.

Machining of Metals

American Society for Metals, Cleveland, 1938. Cloth, 6 x 9 in., 177 pages. Price $2.50.

Five lectures are included: *The Physics of Metal Cutting,* by H. Ernst; *Machinability of Ingot Iron, Wrought Iron, S.A.E. Steels, and Stainless Steels,* by H. B. Knowlton; *Machinability of Cast Steel, Cast and Malleable Iron,* by J. W. Bolton; *Machinability of Tool Steels,* by A. H. d'Arcambal and W. E. Bancroft; and *Machining of Non-ferrous Metals,* by H. P. Croft.

In addition to giving a very good picture of the general problem of machinability, some of the specific data are very interesting. Ernst's demonstration of the effect of the temperature of the metal cut, leading to the prognostication that machinability may some day be commercially controlled by cooling to very low temperature, is in this class. Bolton finds that phosphorus in medium-strength cast iron tends to improve machinability if the chips are kept out of the path of the tool. It is interesting to note that the explanation for the behavior of phosphorus is that it reduces the "ductility" of cast iron. Both Bolton and Croft emphasize the value of carbide tools for machining alloys with firmly held abrasive particles, like high-phosphorus strong cast iron and aluminum-silicon alloys. All the authors bring out clearly the relation between structure and machinability.

The title is something of a misnomer, for a discussion of machining would involve tool compositions, angles, speeds and feeds, and cutting compounds. While incidental data on some of these points are included, especially in the appendix to Knowlton's discussion, the emphasis is laid on the properties of the metal cut. This attention to machinability rather than machining unifies the whole series and leaves the reader with a clear-cut impression. The book is decidedly worth its price.—H. W. GILLETT.

Conventions in Early 1939

Dates have been announced for the 1939 conventions of four technical organizations. They are as follows:

The annual convention of the American Institute of Mining and Metallurgical Engineers (A.I.M.E.) will be held at the Engineering Societies Building, New York, Feb. 13 to 16.

The regular yearly conference of the Open-Hearth Committee of the A. I. M. E. is scheduled to be held at the Cleveland Hotel, Cleveland, April 26 to 28. The Blast Furnace Committee of the same society will join in this conference.

The Spring Meeting of The Electrochemical Society will be held at the Deschler-Wallich Hotel, Columbus, Ohio, April 26 to 29.

The annual convention of the American Foundrymen's Association has been arranged as a technical meeting without an exhibition in Cincinnati. The date is May 15 to 18.

The Spring Group Meetings of the Committees of the American Society for Testing Materials will be held in Columbus, Ohio, March 6 to 10. The annual convention of the A. S. T. M. is set for Atlantic City, N. J., June 26 to 30. An exhibit will be a feature.

Annual Show of Tool Engineers

Details of the second annual Machine and Tool Progress Exhibition, to be held in Detroit, March 14 to 18, 1939, have been announced by Frank A. Shuler, Chrysler Corp., and chairman of the show committee. The show will be held in Convention Hall, Detroit, the locale of last year's startlingly successful exhibition. According to reservations already being received at the headquarters' offices of the American Society of Tool Engineers, sponsors of the show, the exhibition will roughly triple the size of the 1938 exhibition. Exhibits will cover all forms of machines, tools, equipment and processes of interest to manufacturing executives ("Tool Engineers") in the mass production industries.

As a result of the unprecedented demand for space it has been decided to limit exhibit space for each exhibitor. Exact limitations have not as yet been announced as these will have to be approved by the committee as a whole. Practically every exhibitor from last year's show, however, has requested larger space at the 1939 show.

The committee is also planning to secure the cooperation of exhibitors in seeing that the exhibits themselves are of the "operating" type.

Light-Weight High-Speed Passenger Trains

The extent to which the railroads have been able to recapture some of their lost passenger traffic and revenues through the introduction and operation of light-weight trains is factually revealed in a 68-page report "Streamline, Light-Weight, High-Speed Passenger Trains," prepared for the Edward G. Budd Mfg. Co. by Coverdale & Colpitts, consulting engineers, New York. The report discusses the general background and impelling forces behind the trend to light, fast passenger trains, then analyzes in detail the construction, operating factors, growth of traffic and revenues and expenses of each of the new trains.

Approximately 60 individual trains are discussed, some made by Pullman-Standard Car Mfg. Co., some by Budd, some by American Car and Foundry Co. The Pullman Co. has tended to feature aluminum alloy as the weight saving medium but has used some low-alloy and stainless steels; Budd's greatest contributions have been the use of high-tensile stainless steel and the shot welding process in fabrication; A. C. F. has employed low-alloy high strength steels in some trains and aluminum in others. Also important have been the devising and adapting by Electro-Motive Corporation of a 2-cycle Diesel engine practicable for high-speed train service.

In all cases where it was possible, in preparing the report, to segregate the effect of introducing a new train from other effects on traffic volume, a decided growth in traffic could be attributed to passenger acceptance of the innovation. In one case where a new light-weight train was periodically replaced on a certain run by a conventional train, a noticeable falling-off in traffic occurred during each replacement period. It is clear from the opinions given by officials of the various lines that a large proportion of the traffic on the new light-weight, high-speed trains has been newly created or retrieved from the highways.

The outstanding facts that the report reveals, however, are the great popularity and financial success attained in the operation of these trains. For this, much credit must go to the metallurgical engineers whose intelligent application of modern metals and alloys has assisted a harassed industry in increasing its revenues.

Tool Engineers Charter 23rd Chapter

The American Society of Tool Engineers' twenty-third chapter was chartered Dec. 2 at an organization meeting held at the Fort Armstrong Hotel at Rock Island, Ill. To be known as the Tri-Cities Chapter, it will include the entire industrial district around the cities of Moline, East Moline, Rock Island, Ill., and Davenport, Iowa. Fifty-five charter members at the organization meeting elected Otto R. Reller, production manager, Moline Tool Co., as chapter chairman; Joseph B. Morganthall, chief tool designer, John Deere Wagon Works, vice-chairman; Kenneth C. Jasper, tool designer, Rock Island Arsenal, secretary; and W. Z. Fidler, chief draftsman of Reynolds Engineering Co., Rock Island, Ill., treasurer.

Walter F. Wagner, President of the American Society of Tool Engineers and Ford R. Lamb, Executive Secretary, presented the Chapter with its charter at the organization meeting.

● The Chas. Taylor Sons Co. has recently appointed the International Allied Engineering Co. as exclusive sales representatives on "P. B. Sillimanite" and refractory specialties in Argentina, Brazil, Chile, Peru and Uruguay. The company can now offer Sillimanite products to the metal trades in all countries of this hemisphere.

MISCO CYANIDE, LEAD AND SALT POTS

Misco pots are long life pots. This is proven by service records up to 20,000 hours . . . That is why more than 100 users of pot furnaces specify Misco cyanide, lead and salt pots exclusively . . . Misco pots are sound and correctly proportioned to achieve maximum operating efficiency. Misco has many standard designs and more than 200 stock sizes. Designs for special requirements will be furnished gladly. Misco's experience in producing thousands of cyanide, lead, and salt pots is at your disposal.

MICHIGAN STEEL CASTING COMPANY

One of the World's Pioneer Producers of Heat and Corrosion Resistant Alloy Castings

1981 GUOIN STREET, DETROIT, MICHIGAN

MISCO ROLLED THERMOCOUPLE PROTECTION TUBES

more uniform than any cast tubes

Misco protection tubes are recommended for use under the most corrosive or oxidizing conditions in furnaces and in liquid heating mediums at temperatures up to 2200°F. Misco tubes are sound throughout. Cutaway section clearly shows uniform wall thickness at every point. They are made in all diameters and all lengths with threaded or plain ends.

Heat and Corrosion Resistant Alloys

{A dependable source of supply for Furnace parts, Chain, Roller rails, Furnace conveyor rolls, Trays, Carburizing and annealing boxes, Retorts, Lead and cyanide pots, Dipping baskets.}

Kuhlman Electric Co. Absorbs Detroit Electric Furnace Co.

The Kuhlman Electric Co., Bay City, Mich., has purchased the Detroit Electric Furnace Co.'s business and will hereafter operate it as the Detroit Electric Furnace, Division of Kuhlman Electric Co., Bay City, Mich.

There will be no interruption to the servicing of Detroit electric furnaces. The same sales, service and production personnel which have been with the company for many years will continue in the conduct of the company's business under the direction of A. E. Rhoads. Kuhlman Electric Co., as a manufacturer of transformers for almost a half century, was one of the earliest builders of furnace transformers. They have designed and built the transformers for several hundred installations of Detroit Electric Furnaces during the past 20 years. The Detroit Electric Furnace Co. reports a substantial back-log of furnace orders on hand. Several of these will be completed and shipped from Detroit; the remainder will be built on schedule and shipped from Bay City early in 1939. All correspondence should be addressed to the company at Bay City, Mich.

Air Filter Research at Mellon Institute

Dr. Edward R. Weidlein, director, Mellon Institute, Pittsburgh, has announced the establishment of an Industrial Fellowship in that Institution by the American Air Filter Co., Inc., of Louisville, Ky. This fellowship will investigate broadly materials of value in the construction of filters for air-conditioning systems. It will be the aim to gain through this research new knowledge to effect all possible improvements in the devices manufactured by the donor, and in this work the Fellowship will have the direct cooperation of specialists on the staff of the Multiple Industrial Fellowship on air hygiene in operation in the Institute.

Dr. Frank F. Rupert, who has been appointed to the Incumbency of the Fellowship, has been a member of Mellon Institute since 1913.

Dr. Sachs Joins Case Faculty

Dr. George Sachs, prominent European authority on physical metallurgy, will join the faculty of Case School of Applied Science in February, as recently announced by Prof. K. H. Donaldson, head of the metallurgy department. Dr. Sachs will begin his work at Case with the opening of second semester classes on Feb. 6 and will supervise X-ray and research work in the graduate division as well as teach undergraduate courses in the physics of metals.

He has done intensive work in industrial metallurgical research and will come to Case from the Baker Chemical Co. in New Jersey where he is head of the precious metals department. He was born in Moscow, Russia, and educated at the Technische Hochschule in Berlin where he received his bachelor's degree in civil engineering in 1920 and his doctorate degree in mechanical engineering in 1921.

Francis Hodgkinson Receives Holley Medal

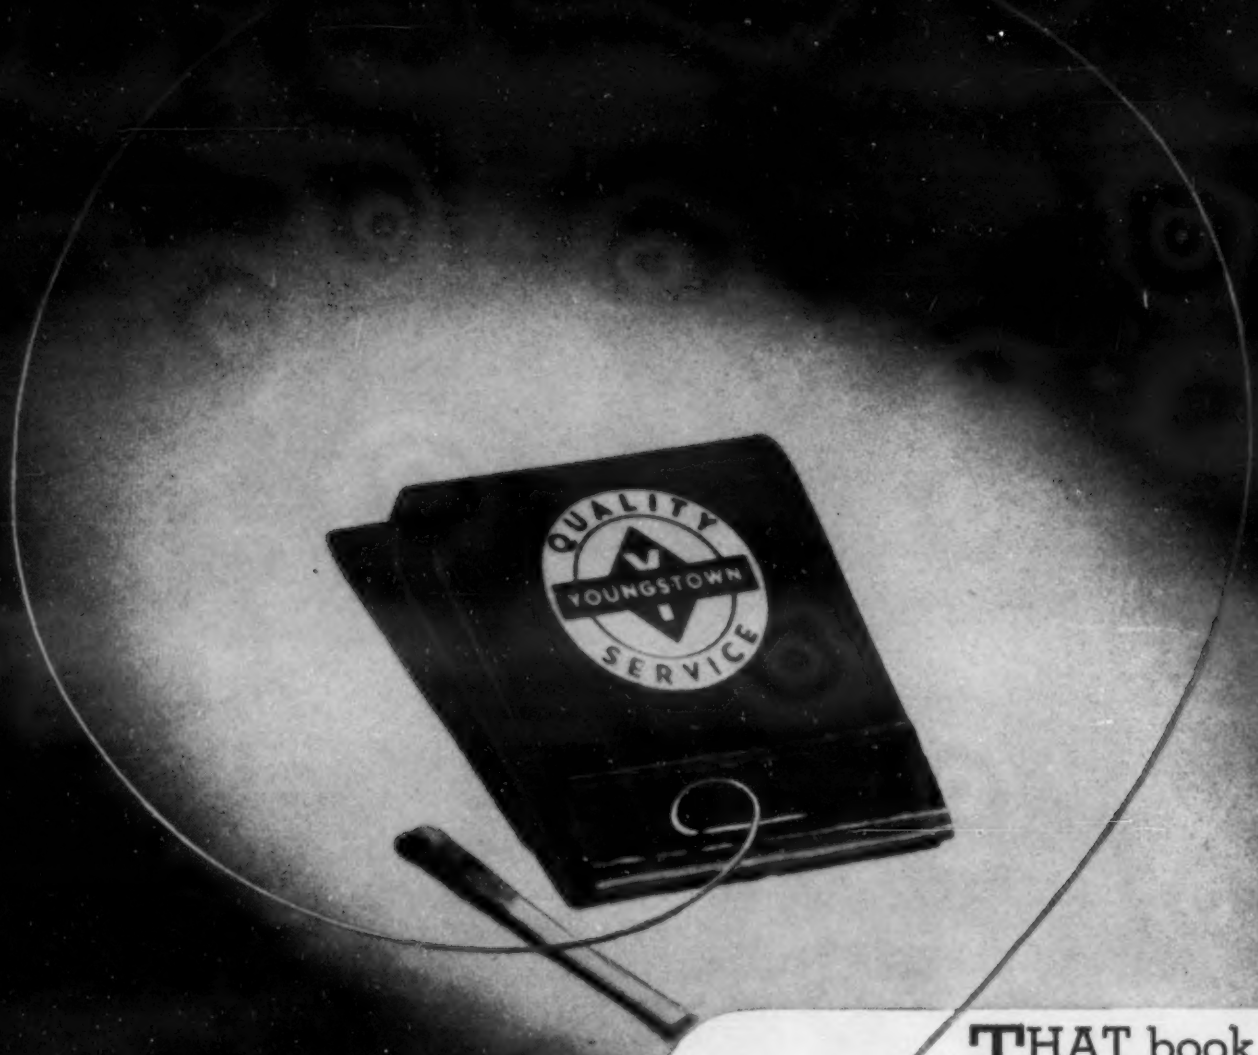
The Holley Medal of The American Society of Mechanical Engineers was awarded to Francis Hodgkinson, honorary professor of mechanical engineering at Columbia University and former associate of George Westinghouse, for "meritorious services in the development of the steam turbine." The award was made during A.S.M.E. Honors Night ceremonies at the Engineering Societies Building, 29 West 39th St., during the Annual Convention in New York.

Stainless Steel's 25th Anniversary

More than 100 of the leading members of the steel industry gathered to commemorate the "twenty-fifth Anniversary of the Discovery of Stainless Steel" at a dinner held in the Duquesne Club on Dec. 13. Addresses were delivered by Dr. V. N. Krivobok, associate director of research, Allegheny-Ludlum Steel Corp., who spoke on "The Origin and Development of Stainless Steel"; L. S. Bergen, associate director of metallurgy and research, Crucible Steel Co. of America, on "The Standardization of Stainless Alloys," and John H. Van Deventer, editor of *The Iron Age*, on the "Commercial Aspects of Stainless." A tribute in the form of a toast was paid Harry Brearley, discoverer of stainless steel in 1913, by the toastmaster, Benjamin F. Fairless, president, U. S. Steel Corp.

Bethlehem Granted License to Make "Ledloy"

The Bethlehem Steel Co., Bethlehem, Pa., has taken out a license to make leaded steels under Inland patents. Lead-bearing steels, as recently developed by Inland, are reported as becoming increasingly popular with manufacturers. It is stated that tests have shown that the physical properties of steel are unaffected by the lead additions, and that at the same time remarkable records for increased machinability and greatly lengthened tool life are being reported daily.



● The "Elastuf Group of Related Machinery Steels," developed by the Horace T. Potts Co. of Philadelphia, are now available over a large section of the Eastern industrial territory. Formerly distributed entirely through Potts warehouses in Philadelphia and Baltimore, and through Brown-Wales in Boston, these special formula steels can now be obtained through Beals, McCarthy & Rogers in Buffalo, and Equitable Equipment Co. in New Orleans. The Elastuf steels include a number of grades of machinable steels offering high tensile properties without the need for intermediate heat treatments.

● Norbert Stern, Pittsburgh, president of Barium & Chemicals, Inc., Willoughby, Ohio, announces that they are successors to the J. H. R. Products Co. of Willoughby, which has for the past 20 yrs., manufactured high grade barium compounds and other products. Dr. M. J. Rentschler, who has been associated with the J. H. R. Products Co. since its inception as director of research, will continue in the same capacity with Barium & Chemicals, Inc. The company produces all standard barium compounds, hydrogen peroxide, J. H. R. tank-lining compound, anti-scumming dust and "Bar-ide."

● The Meehanite Metal Corp., Pittsburgh, announces the licensing of the following companies to manufacture Meehanite metal under the Meehanite processes: Valley Iron Works, St. Paul, Minn.; Barnett Foundry & Machine Co., Newark, N. J.; Herbert Morris, Ltd., Loughboro, England; and Douglas Fraser & Sons, Ltd., Arbroath, Scotland.

● The appointment of Ralph Hare as New England representative of The Electro-Alloys Co., Elyria, Ohio, is announced. Mr. Hare will continue to make his headquarters at West Hartford, Conn.

● The appointment of D. J. Richards as manager of steel mill sales is announced by E. F. Houghton & Co., oils, leathers and metal working products, Philadelphia.

400 Miles of Steel... to light your Cigarette

THAT book of matches in your pocket would fall apart except for that inconspicuous piece of stapling wire. *It takes approximately 444 miles of that wire every day to supply the enormous demand for book matches.*

Steel is even more important in almost every act of your daily life. Many food delicacies come to you in tin plated steel cans and are cooked on a steel range; the modern plumbing and heating of your house would be impossible except for steel; your clothes, glasses, watch, shoes.... all contain vital steel parts; you probably travel in a steel automobile or train to a steel framed office building or factory, to work at a steel desk or machine.

All the comforts and conveniences of modern life, which have come to be considered necessities, have been made possible by modern refinements in steels. Such refinements in steels do not just happen .... Youngstown maintains a great laboratory and an experienced organization, always working with customers to find the steel best suited to their needs and products.

trends

Lighter Transportation Equipment

Our first article this month—Aluminum Alloys in the Railroad Industry—is another which discusses a trend in the substitution of alloys or alloy steels for plain carbon steels, particularly in transportation equipment, so as to decrease the dead weight and to increase the pay load without sacrifice of essential properties. The author presents the case for aluminum alloys. This article supplements the review of the present status for the low-alloy steels in our October issue. Undoubtedly the greater use of both aluminum alloys and low alloy, high strength steels is assured. Ultimate rehabilitation of railroad equipment alone seems a certainty.

Molybdenum

The trend in the demand for molybdenum as an alloying element is steadily upward. It is not too late to call attention to the fact that Government data for 1937 show that production of molybdenum concentrates in 1937 were 74 per cent larger than for 1936 and 155 per cent in excess of 1935. The statistics also show that shipments of Mo-contained material were 67.7 per cent greater than those of 1936 and 176 per cent over those of 1935.

Viewed from any angle these facts tell an encouraging and significant story—expanding recognition of the value of this alloying metal and the growing breadth of the alloy steel and iron industry as a whole.

German and American Steel Output

For the first time in many, many years and possibly in history, the pig iron and the steel output of Germany for the first half of 1938 exceeded that of the United States. Germany made 10,581,960 metric tons of pig iron as compared with 7,873,000 gross tons for American furnaces. In steel the German total was 13,204,394 metric tons while the American was 10,819,144 gross tons. The American iron and steel output has not in recent years been topped by any other country. The 1938 totals are not yet available but it is not unlikely that the comparison will hold true for the year. While this is an interesting and rather startling fact, and while Germany's producing resources are on the increase, when prosperity returns in this country, the above trend will probably be reversed and revert to normal.

Powder Metallurgy

There are accumulating evidences of the future commercial importance of powder metallurgy. For some time the discussions by Hardy and quite recently the paper by Gregory Comstock have presented the present status of this development with a glimpse of its possibilities. Now comes the information that a "seminar course of two hours per week to discuss the problems of powder metallurgy" has been arranged for at Massachusetts Institute of Technology. This will be followed by "a laboratory course the second term on problems connected with the field." Visualization of the probable future developments in this field is not difficult.

Research

That interest in the value of research in metals is not on the wane but is distinctly expanding is demonstrated by the establishing of new research laboratories by industrial companies in the metal industry. Two of the more recent examples of this tendency is the large laboratory of the Jones & Laughlin Steel Co., Pittsburgh, and that of the Crane Co., Chicago. Both of these contain the latest equipment for research in many fields and are manned by scientists who are competent to get results.

Metals and Alloys in Dairy Equipment

We visited the very large exhibit of the dairy industries in Cleveland recently where over $2,000,000 worth of various kinds of equipment was displayed—a very impressive affair. Stainless steel predominated—probably more was assembled in the Cleveland Public Hall than anywhere before in one place as fabricated material. It is only in recent years that the dairy industry has adopted solid metals such as stainless steel, nickel, aluminum alloys and so on. The trend has been and still is decidedly away from coated metals. These were used in the early days.

Scrap Exports

In our October, 1938, issue we called attention editorially to the spectacular demand for American scrap iron and steel, emphasizing the record exports in 1937 of over 4,092,000 gross tons or 341,000 tons per month, mostly to Japan. The 1937 all-time record volume was approximately twice the average exports for 1934, 1935, or 1936. The trend for 1938 has been downward—to Nov. 1, the total had been over 2,406,300 tons or about 240,600 tons monthly, also the bulk to Japan. Despite this downward trend, the average monthly volume still exceeds that for 1934, 1935, or 1936.

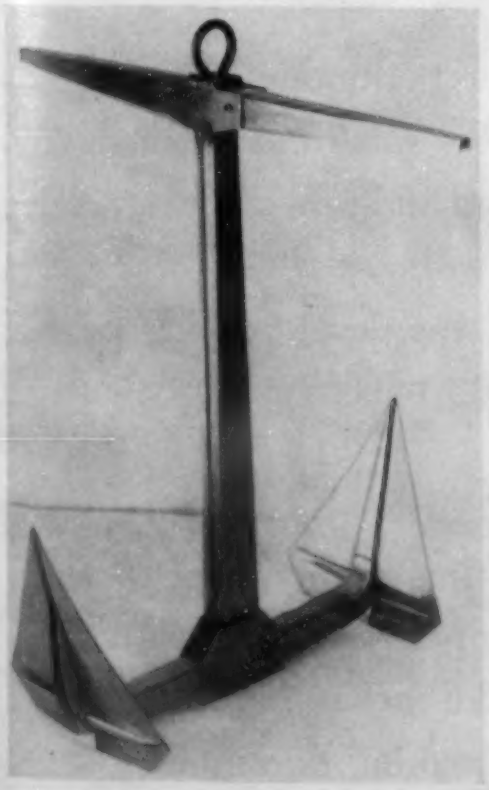
Expansion in Steel Capacity

As the result of technical progress in furnace construction, principally open-hearth, the trend in steel manufacturing capacity in the United States has expanded about 1,030 per cent since 1889 but there has not been a corresponding increase in the number of furnaces—according to the American Iron and Steel Institute. The number of furnaces has expanded only 350 per cent. And the average annual productive capacity of each steel producing unit is about 62,000 tons as compared with 25,000 tons in 1889, an increase of about 150 per cent in 50 years,—truly a testimonial to technical research and a trend likely to continue.

by Edwin F. Cone, Editor

New Equipment and Materials

Manufacturers are invited to send to the Editor items which are suitable for this Department. Illustrations are acceptable, preferably in the form of cuts no more than 2 in. wide.



Lightweight Anchor

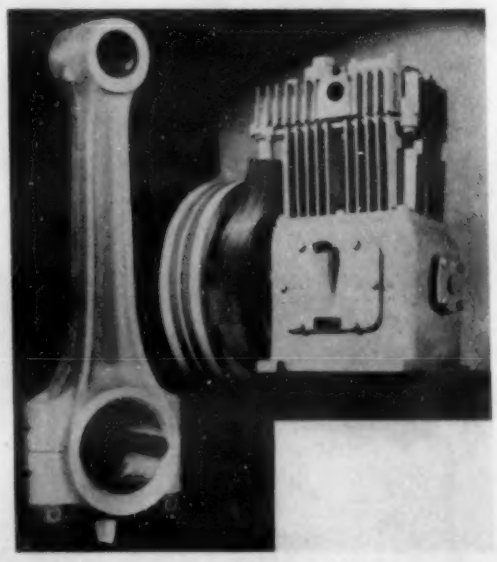
One of the latest developments in the marine accessory field, introduced at the recent motor boat show in New York, is a new lightweight anchor fabricated from high strength Monel metal sheet. It is welded throughout, except where the arms and stock meet the shank. These joints are pinned so that the anchor can be folded for stowing when not in use.

Made in a variety of sizes from 6 to 47 lbs., the anchor is so designed that the 11-lb size will hold a boat 38 ft. in length. With the conventional type of anchor the general rule is to allow 1 to 2 lbs. in anchor weight for each foot of boat length. This lightness of weight is made possible by the design of the anchor combined with the inherent strength of Monel.

Arms of the unit are set at right angles to the stock and are equipped with a set of sharp-pointed triangular flukes. These dig deeper and deeper as the pull of the craft is increased. The broad palms of the anchor, which will bury itself completely in bottoms of clay or sand provide an exceptionally strong grip. The anchor will not dig itself out of the bottom until a direct upward pull is exerted on the line. Then, the sharp-pointed flukes readily cut their way out.

The lightweight and small size of the anchor are pointed to as permitting ease of handling and of reducing the danger of damage to the hull and topsides. Monel is highly resistant to corrosion.

Designed and manufactured by the Youngstown Welding & Engineering Co., Youngstown, Ohio, the unit has not yet been assigned a name. This will await the outcome of a prize name contest conducted by the company. It will close on March 15.



Non-Ferrous Alloy, Strong and Hard As Steel

As a recent addition to their line of standard and special alloy non-ferrous castings, the A. W. Cadman Mfg. Co., Pittsburgh, is equipped and qualified to make castings of Cupaloy under license of Westinghouse Electric & Mfg. Co. This new copper alloy, having the desirable thermal and electrical properties and at the same time free from the mechanical weaknesses of copper, is as strong and hard as 0.30 carbon steel, retaining these characteristics at the high operating temperature of 750° F. in continuous service, is now available in cast shapes made by the Cadman Company—a well known non-ferrous foundry established in 1860.

Some of the uses for Cupaloy include: Resistance welding electrodes, spot welding tips, holder jaws and clamps, welding discs, arc welding electrode holders, welding machine structural parts (non magnetic) and welding bells; motor and generator slip rings, coil conductors and commutator bars and segments, brush springs and holders; switch gear bodies, contact and clapper pads; transformer terminal studs and structural parts subjected to high physical stresses and heavy current; controller, overload relay, circuit breaker and safety switch structural parts and contacts; trolley wheels and gliders, third rail collector shoes, electroplating structural parts carrying heavy current, springs of all types where a high ratio of conductivity to strength is required; fuse clips, electric marking points, electrically upsetting rivets. Aside from castings made from any conventional shape that may be produced by regular foundry technique Cupaloy is also available in rolled or drawn round, square and rectangular bars, strips, forged discs and extruded shapes.

Aluminum Connecting Rods

With the advances in aluminum technique and with the development of new, stronger alloys, the possibilities of aluminum connecting rods are again being considered very carefully by engineers in the automotive field. The rod, shown herewith, was recently developed by the Bohn Aluminum and Brass Corp., Detroit, for the new line of Quincy air compressors. This

compressor was designed to have exceptionally high over-all efficiency in delivering the greatest amount of air possible per unit of power consumed. Saving weight in the reciprocating parts was highly essential for mechanical efficiency as well as for smooth operation.

By adopting the "Bohnalite" connecting rod illustrated, a saving of 40 per cent in weight over steel was accomplished with the consequent reduction in vibration and mechanical losses. The illustration shows the compressor with an enlarged view of this forged aluminum connecting rod.

Induction Furnace for Sintering

Chas. Hardy, Inc., 415 Lexington Ave., New York, announces "a development of paramount importance to the field of powder metallurgy." It is an induction furnace for sintering metal powders at extraordinarily high frequencies. By arrangement with the Ohio Crankshaft Co. —Tocco Division—Cleveland, the Hardy organization is the exclusive distributor of "Hardy-Lepel" high frequency sintering furnaces and for Lepel electric power converters for powder metallurgy applications.

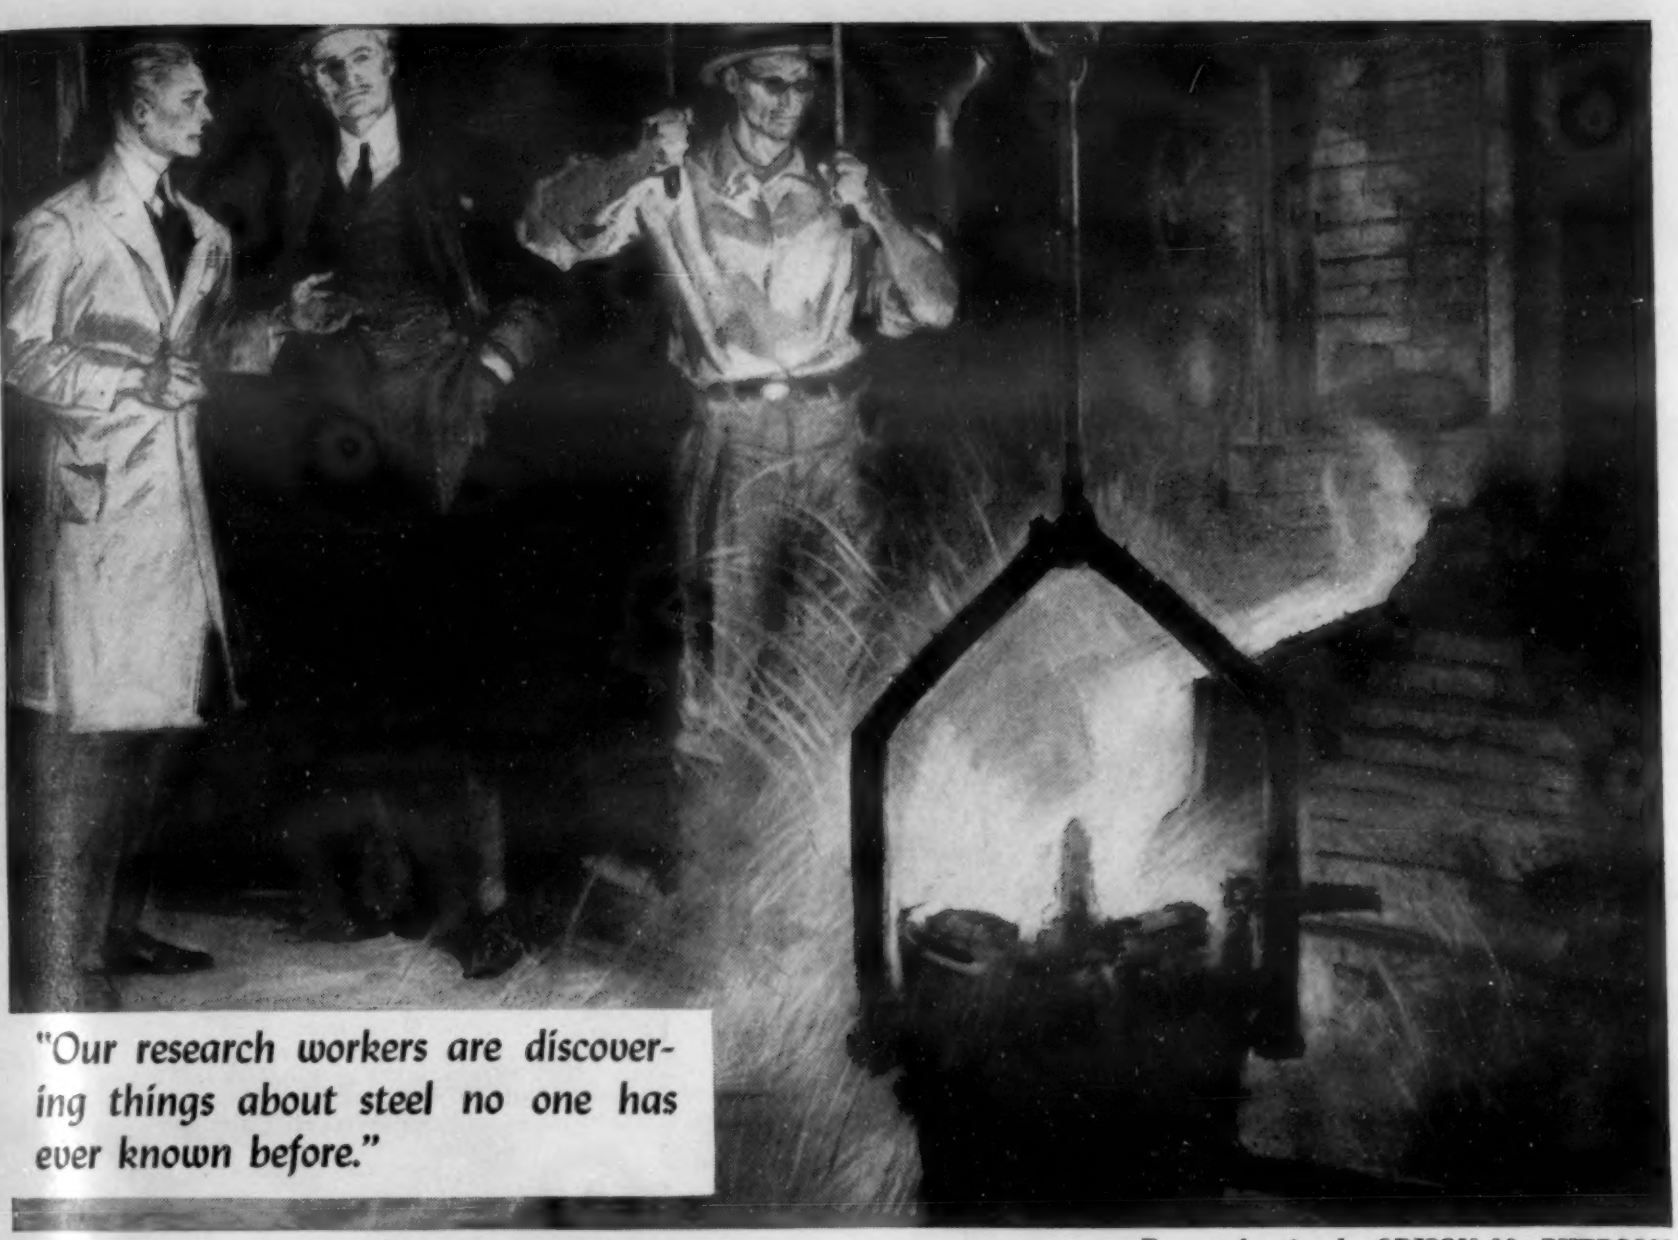
MAKING STEEL BY THE POUND...

HOW THE LITTLE OPEN-HEARTH FURNACE IN JONES & LAUGHLIN'S NEW PILOT PLANT LABORATORY DIRECTS THE MANUFACTURE OF **CONTROLLED QUALITY** STEEL IN ITS WORKS.



"Here in our new Pilot Plant laboratory—the first and only one of its kind—our metallurgists and engineers designed and built this small open-hearth furnace to facilitate research in steel making. We develop and prove new formulas here and new quality controls for the big furnaces in the steel works.

"This small furnace makes steel in only 1500-pound lots, yet the developments proved here are readily applied in the large furnaces which produce 100 tons of steel or more in a single operation.

"The man in the old battered hat you see operating this 'baby' furnace is a college graduate—a research metallurgist. His two helpers have been making quality steel all their lives in the tradition of craftsmanship built up by J & L over a period of 89 years. They can read temperatures by peering into a furnace—they can tell the carbon content of steel by looking at a broken sample—they are masters of the art of making fine quality steel.

"But now, in our works, as in our laboratory, this art—this craftsmanship—is reinforced by science. With sensitive instruments, we measure and regulate temperatures, analyze

TO IMPROVE IT BY THE TON

From a drawing by ORISON MacPHERSON

the molten steel of the furnaces, make experiments in the Pilot Plant, all to obtain complete control of quality in our commercial production. With the small experimental furnaces and pilot rolling mills in this laboratory, our research workers are discovering things about steel no one has ever known before.

"How does making steel by the pound help you customers who use it by the ton? By improving properties of steels for all your products—developing new steels—opening new fields for you through wider and more profitable use of J & L Controlled Quality Steel."

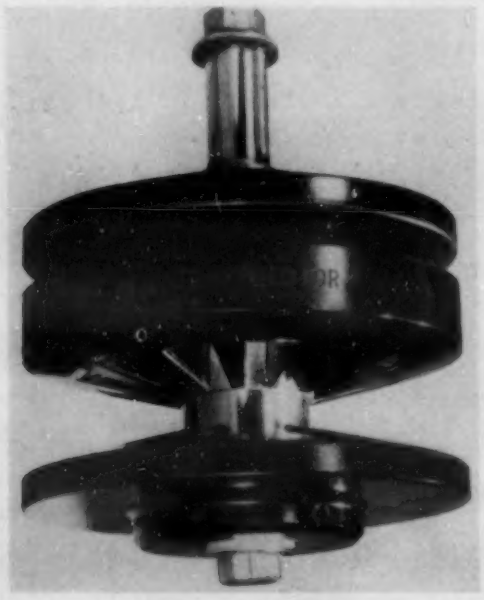
JONES & LAUGHLIN STEEL CORPORATION

AMERICAN IRON AND STEEL WORKS

PITTSBURGH, PENNSYLVANIA

J&L STEEL

J & L—PARTNER IN PROGRESS TO AMERICAN INDUSTRY



A "Speedmaster" Drive

Continental Machine Specialties of Minneapolis, announce an improved design and lower price for their "Speedmaster Variable Speed Pulleys." These new infinitely variable speed pulleys are molded of solid high impact strength Bakelite, accurately trued and balanced before final assembly. An improved pressure lubricated bronze sleeve allows the splined center sheave member to operate freely, regardless of load or speed.

The new construction is available in two sizes, a 3½-in. dia. size for drives up to ½ hp capacity and a 6½-in. dia. size for drives up to 3 hp capacity. The pulley is said to be very flexible in its adaptability to both "straight line" and "angular" drives. Interposed between motor and driven unit, the position of the pulley can be changed to vary the center distances of the Speedmaster pulley in relation to the drive and driven sheaves. The belts thus assume smaller or larger operating pitch diameters through the action of the variable pulley faces. Control of speed is made through a quick action lever, or a handwheel allowing control of speed within 1 rpm. The entire unit is free floating so that belt alignment is accurately maintained at all times.

Advantages claimed by the manufacturer for the improved Speedmaster are: A 6-to-1 up to a 40-to-1 ratio of infinitely variable speed, the use of standard "V" belts, and long belt and pulley life because of the molded plastic work faces.

This wide range transmission was originally developed for use in the company's "Doall" contour band sawing machine and was later produced as a separate unit for general applications.

Self-Lubricating Bearing Bronze

The Johnson Bronze Co., New Castle, Pa., has put on the market a product which it terms a new type of self-lubricating bearing bronze. It's trade name is "Ledaloyl." Although primarily a sintered type of bearing, it is said to have characteristics never before available through the process of pre-alloying the basic metals, allowing the introduction of both lead and graphite. Pre-alloying is also said to create a uniform grain structure and a thoroughly homogeneous material. A porous structure, which will retain up to 35 per cent oil by volume, when the bearing is vacuum impregnated, is secured by including a definite amount of volatile matter. The capillary structure of the bearing thus permits a flow of oil to the shaft when needed and absorption when not in use.

A Plated Steel

The Standard Steel Spring Co., Coraopolis, Pa., has opened a new electroplating plant especially designed to handle large sections of steel for finishing with nickel plating of a pore-free type, according to W. F. Rockwell, chairman of the company's board of directors.

First shipments from the new plant will go to the Texas oil fields where the inroads of corrosion are increasing production costs, he said. Thorough trials of this pore-free coating which ranges up to 20 times the normal thickness of nickel plating, have demonstrated its resistance to corrosion in the wells. Besides the oil fields the new material is designed for uses in which ordinary steel corrodes badly, thus extending the market for steel in the manufacture of barrels, tanks and other containers for shipping and storing corrosive chemicals.

The new electroplating process which makes this material possible requires accurate technical control, Mr. Rockwell said, but as the process is largely automatic, the results can be duplicated regularly in commercial production. The nickel deposit which constitutes the heavy plate is malleable and withstands abrasive as well as corrosive attack. Thus this new product adds to the list of economical structural materials with corrosion resistant surfaces.

A fellowship has been established at the Mellon Institute of Industrial Research, Pittsburgh, to study the process and assure its scientific application to new fields of use.

Colloidal Graphite Solves Oven Lubrication Problem

Conveyor chains operating in high temperature zones, such as in baking and enameling ovens, can now be more effectively lubricated as the result of the development of a new product, it is claimed. Common lubricants cannot be used since they would burn off. Colloidal graphite had been tried with varying success, the graphite being suspended in various liquids. The difficulty was with the carrier. Oil, for instance, would burn off, forming undesirable carbon. Smoke and odor were other problems.

The solution was found through the development by Acheson Colloids Corpn., Detroit, of a new form of colloidal graphite, so finely divided that it could be suspended in suitable volatile liquids. The liquid, kerosene in this case, merely evaporates, leaving a very thin deposit of fine colloidal graphite on the surface. Experience has shown that this film of graphite, although extremely thin, provides lasting and economical lubrication for the difficult-to-reach friction surfaces under high operating temperatures.

Hot Solution Plating Barrel

A noteworthy advance in plating barrel construction is said to be embodied in the new Mercel plating barrel tank made by the Hanson-Van Winkle-Munning Co., Matawan, N. J. This tank which is designed for hot solutions, employs a unique method of exhausting the fumes. A series of small ducts directly over the anode rods connect with the main duct on the side. These individual ducts do not interfere with the placement of the cylinders into the tank in their respective saddle brackets, nor do they leave any unsightly cumbersome ducts along the side or above the tanks. The unit is neat in appearance, compact and thoroughly effective.

A Protective Shield for the Face

Willson Products, Inc., 269 Thorn St., Reading, Pa., announces a new "Protecto-Shield" for guarding face of workers in light grinding operations, wood working, spot welding and other occupations where protection is desirable.

The Willson Protecto-Shield permits clear vision in all directions. It is made of thick transparent cellulose acetate, is well ventilated and large enough to fit comfortably over correction spectacles. The shield extends well back along the sides of the face. It is easily thrown back when not in use. A special Willson knitted sweat pad provides unusual comfort. It is so light in weight that workers have no objection to wearing it.

The adjustable molded rubber headband and all other parts are easily replaceable. Shield may be had in clear, amber, or green transparent cellulose. The manufacturer will gladly furnish complete information, literature and prices on request.

Electric Unit for Industrial Heating

A high-speed Calrod heating unit has been developed by the General Electric Co., Schenectady, N. Y. It is for industrial applications that require temperatures as high as 1500 deg. F.

Although standard listed ratings range from 750 to 3500 watts, and effective heating lengths ordinarily range from 18 to 84 in., other sizes and ratings can be manufactured as required. Among uses of product are applications in high-temperature air heating, industrial ovens with air temperatures up to 1000 deg. F., hotplates, and various metal surfaces.

"Lapix"—for Open-Hearth Operations

A new product has recently been introduced by E. F. Houghton & Co., Philadelphia, for use in open-hearth departments in the treatment of fully killed steel. This is known as "Lapix", a finely powdered insulating material.

Lapix is applied to the top of the ingot head in the hot top immediately after pouring. It spreads over the exposed metal, forming an insulating blanket that, it is claimed, will keep the metal molten a sufficient time for gases to escape and enclosures to rise to the top. Also it is said that Lapix will materially reduce top discards, and definitely reduce porosity and secondary pipe where such tendencies occur.

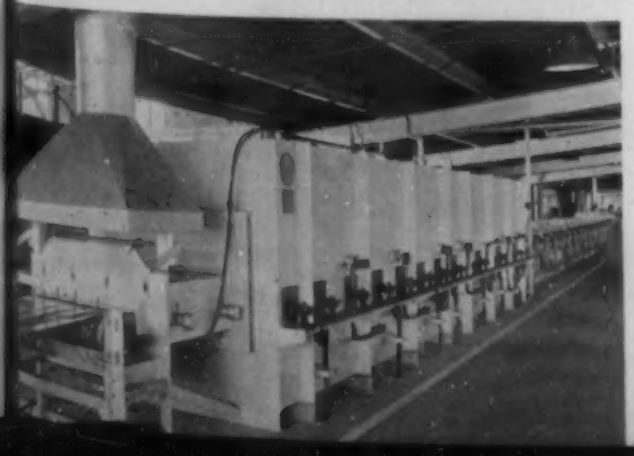
ARMSTRONG'S BRICK

Cut fuel costs, help assure more uniform temperatures

IN THESE MODERN ELECTRIC EF FURNACES FUEL FIRED FURNACES



Top photograph shows charging end of an EF continuous chain belt conveyor type furnace for scale-free hardening bolts and other miscellaneous products. At left is illustrated an interior of the same type furnace, showing the installation of Armstrong's Insulating Fire Brick. These furnaces are built in various sizes and capacities to handle almost any production required from 300 to 2,000 lbs. per hour.

...w: This special atmosphere, continuous bright annealing furnace is ...of several gas fired, radiant tube furnaces recently placed in operation ...he Electric Furnace Co. It is insulated with Armstrong's Insulating ... Brick for maximum efficiency and economical operating costs.

~ ~ ~

...ow: Charging end of an EF continuous atmosphere electric fur... for bright annealing cold rolled steel in strip form. Like the other ...es shown here, it has the efficient insulation of Armstrong's Brick.

DESIGNED and built by The Electric Furnace Company, Salem, Ohio, these furnaces have the efficient, money-saving insulation of Armstrong's Insulating Fire Brick.

Chief among the advantages of Armstrong's Brick are: low thermal conductivity, high crushing strength, high spalling resistance, and lightness in weight. The exceptionally high insulating efficiency of these brick is the result of the fine cellular composition produced by burning out finely ground cork particles. Their use assures lower fuel costs, more accurate temperature control, and increased operating efficiency. That is why Armstrong's Brick are the choice of so many leading furnace manufacturers and plant operators.

For engineers wishing to make open specifications for high temperature insulation, Armstrong will gladly furnish complete specifications outlining the standards required for the different physical characteristics with permissible tolerances. Write today for samples, prices and descriptive literature. Armstrong Cork Co., Building Materials Div., 982 Concord Street, Lancaster, Pa.

IMPORTANT FEATURES OF ARMSTRONG'S BRICK

1. Ample insulating value
2. High crushing strength
3. Accurate sizing
4. High spalling resistance
5. High salvage value
6. Complete line for wide temperature range
7. Ability to withstand handling in shipping and installing
8. Special shapes of all types and sizes
9. Easily cut on the job
10. Stocks available in principal cities
11. Laying cements with same physical characteristics as brick
12. Complete line of refractory facing cements for protective coatings.

HIGH TEMPERATURE INSULATION

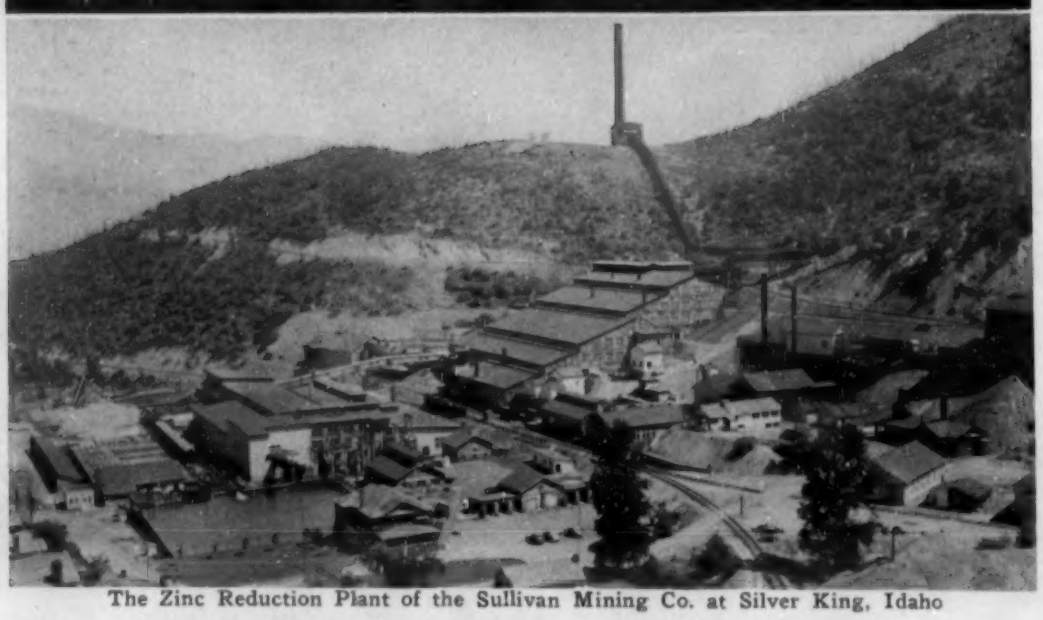
INSULATING FIRE BRICK
HIGH TEMPERATURE BLOCK
PLASTIC CEMENTS
DIATOMACEOUS EARTHS

Die Blocks, Electrically Heated

The Cooley Electric Mfg. Corp., Indianapolis, Ind., has put on the market a pair of die blocks for forming thin metal discs under heat and pressure. These die blocks are formed by casting aluminum around an electric element which is formed of the usual wire coils, but which are embedded in a refractory that in itself is more than 50 per cent metal, yet has a high diaelectric. The heat from the coils is conveyed rapidly and uniformly to the surface of the block, because of the ceramic used.

The elements can be formed in a variety of shapes such as rectangular, cylindrical, or rods and the entire structure is sufficiently strong to permit machining after casting. Aluminum, brass, copper, and iron have been successfully used as the casting material.

Electric Heater with Water-Cooled Electrodes



A line of Berwick electric heaters, comprising seven models which differ principally in capacity and in the number of electrodes used, has been introduced by the American Car & Foundry Co., New York. The Model, known as the No. 4 two-electrode type "LS" metal heater, is provided with low temperature electric eye for working down to 1100 deg. and up to 2300 deg. F. It is equipped with air cylinders for giving any desired pressure on the piece being heated. Electrodes are water-cooled. This type of heater may be used on both steel and non-ferrous metals, for upset and drop forge work. The range is from ¼ to 1½ in. in dia., and practically any length heat can be obtained from 1 up to 23 in.

Hydraulic Pump for High Test Pressures

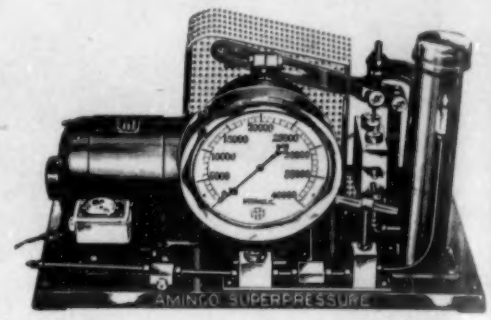
A new motor-driven hydraulic pump, capable of developing pressures up to 30,000 lb. per sq. in. (2000 atmospheres), also a dead weight gage (free piston gage) for measuring the pressures developed, are announced by the American Instrument Co., Silver Spring, Md.

The pump is used for creating very high test pressures for determining bursting strength of cylinders and spheres; for operating high-pressure and hydraulic intensifiers; and for carrying out experiments to determine the effect of extremely high pressures and sudden release on various materials. Further details are available from the manufacturer.

10th ANNIVERSARY

The Zinc Reduction Plant of the Sullivan Mining Co. at Silver King, Idaho

BUNKER HILL COMPLETES 10 YEARS OF UNINTERRUPTED OPERATION



With the start of 1939 the Bunker Hill zinc plant completes ten years of uninterrupted operation. Bunker Hill pioneered the production of 99.99+% zinc and made it available to industry three years prior to the appearance of any comparable metal. New achievements in many industries were made possible; these ranged from practically revolutionary changes in the physical properties and applications of die casting, to increased flexibility and corrosion resistance of zinc coatings on galvanized strip and wire.

The extent of these changes can be demonstrated, for example, by the enormous increase in the use of zinc base die castings. In 1928 the die casting industry consumed 30,000 tons of slab zinc. Since Bunker Hill showed the way to the production of four-nine zinc in commercial quantities, the consumption of slab zinc by die casters rose to 88,000 tons in 1937 —the last figure available. In view of these achievements, rarely duplicated in the metal industry, the 10th anniversary of Bunker Hill is well worth noting.

99.99+%

ST. JOSEPH LEAD CO.
280 PARK AVENUE • NEW YORK
ELdorado 5-3200

BUNKER HILL ZINC

Rigid, Low-Resistance Lead Anode

Securus Lead Products Co., 6410 Detroit Ave., Cleveland, announces a new type of lead anode for chromium plating and other electrolytic processes (patent applied for). The advantages claimed are; unusually low electrical resistance, resulting in saving generator power; more even current distribution at all points of the active surface; and unusual mechanical rigidity against bending and warping.

The construction embodies a lattice type frame of strip copper, upon which is deposited and firmly bonded by a special process, a thin film of pure lead which serves as an integrally-homogeneous basis on which lead is built up to the desired thickness all over. Since all parts of the lead are supported by the highly conductive copper frame by lead-burning or other suitable means, low resistance and great rigidity are obtained at all points. A final treatment with a lead-burning flame consolidates the lead coating to maximum density and assures freedom from porosity and blowholes which might otherwise permit penetration of the solution to the copper itself—a defect not unusual when casting is employed. These anodes are made both in special sizes and to standard dimensions as may be required.

Better Magnet Wire

Eliminating the need for space-consuming protective coatings in many instances, Formex wire, a new and superior magnet wire announced by General Electric Co. at the 1939 winter convention of the A. I. E. E., New York, is insulated with a synthetic resin which is tougher and more flexible than the conventional enamel coatings. The new resin is of the polyvinyl acetal type, while ordinary enamel coatings are composed of drying-oil resins. Since Formex wire requires less space for insulation and protection, it gives the designer new opportunities to reduce the size of many products

Further, electrical properties are as good as those of ordinary enameled wires, and tests show that Formex wire is considerably higher in resistance to abrasion and to the common treating solvents. When severely twisted and then subjected to a temperature of 125 deg C. for 1 hr., ordinary enameled wire cracks but Formex wire is not affected, it is claimed.

The Preparation of Pure Metals of the Titanium Group by Thermal Decomposition of their Iodides. Part IV. Production of Lower Zirconium Iodides in the Preparation of Ductile Zirconium (Ueber die Herstellung der reinen Metalle der Titangruppe durch thermische Zersetzung ihrer Iodide. IV. Das Auftreten niedrigerer Zirkoniodide bei der Herstellung duktilen Zirkons) J. D. FAST. *Z. anorg. allgem. Chem.*, Vol. 239, Sept. 3, 1938, pp. 145-154. Research. Lower iodides of Zr are formed by overheating ZrI_4 in the presence of excess Zr. In the preparation of ductile Zr by heating ZrI_4, the rate of formation of Zr increases markedly at 250° C. Above 300° C. the rate decreases with further increase of temperature as a result of the reaction between ZrI_4 and excess Zr. It is likely that at 400° C. ZrI_4 reacts with Zr to form ZrI_3, while at 500° C. ZrI_2 is formed. Furthermore, above 310° C. ZrI_3 decomposes according to the relation $2\ ZrI_3 \rightleftarrows ZrI_2 + ZrI_4$, and above 430° C. ZrI_2 decomposes according to the equation $2\ ZrI_2 \rightleftarrows Zr + ZrI_4$. As a result of the reaction between ZrI_4 and excess Zr, it is not possible to obtain any further yield of Zr at 250° C. in a reaction vessel previously heated to 400° or higher. HFK (2)

Distribution of Stock. J. P. DOVEL. *Steel*, Vol. 103, July 11, 1938, pp. 48-49. Practical. Angle of repose of ore dumped into blast-furnace over a bell valve is greater than that of coke. It is affected by speed with which valve is opened and amount of clearance between valve and its seat. If bell is opened at moderate speed, ore will start to flow as soon as valve begins to open and will flow gradually as bell opens to take its natural repose. Coke will not begin to flow until valve is almost wide open, when it will discharge rapidly and with a splash, having a flattening effect. This makes possible complete envelopment of ore charge by coke, which acts as a filter, preventing escape of fine ore as flue-dust. This, combined with a larger stock-line area than customary, reduces flue-dust loss to a minimum. Finer ore particles will be near peak of charge, leaving coarser particles near wall and through center. Finest ore can be used without excessive flue-dust losses. Gases will have same rate of flow and same temperature along wall and through center, thus exposing denser portion of ore charge (small particles) around the charge peak to extreme heat from both sides, and causing very rapid reduction of fine ore. Part of CO_2 would be eliminated quickly high up in furnace. The peak circle of ore charge should reach hearth and bosh in its hottest zone, which is on about the same level as tuyeres. Thus, there is a direct relationship between the peak circle of ore charge and diameter at tuyeres. Majority of existing blast-furnaces can be corrected by increasing stock-line diameter. Charging of furnace according to these principles requires an adequate inwall cooling system. MS (2a)

Value of Charcoal as Blast Furnace Fuel (Träkols värde för masugnsdrift) HILDING BERGSTRÖM. *Jernkontorets Ann.*, Vol. 122, No. 6, 1938, pp. 221-257. Original research. The quality of charcoal available to Swedish blast furnaces is becoming less uniform. Spruce charcoal may have a dry weight 10-30% less than pine charcoal; charcoal from slow-growth wood may have 40% higher specific gravity than that from fast-growth. Since fuels are purchased on a volume basis, these variations represent important cost factors. The size of the chunks is also important, since large chunks cannot be packed into as compact a volume as small ones, and for the same weight may vary as much as 40% in bulk volume. Rapid burning results in soft charcoal. Spruce, because it tends to retain its gases swells more than pine during burning. Weight instead of volume should be used as a basis for the sale of charcoal. Among tests suggested are moisture content, loss of weight of dried charcoal on heating under vacuum, rate of O absorption and P content. The latter test is especially recommended, as the cumulative results should finally show from what areas and under what conditions a low P content may be obtained.. HCD (2a)

Influence of Calcium Sulphide on the Viscosity and Melting Point of Blast Furnace Slags. L. TSYLEV. *Metallurg*, Vol. 13, June 1938, pp. 90-97. In Russian. Research. Both synthetic and natural slags were used. The synthetic slags contained 45.00-58.00% CaO, 23.50-38.00% SiO_2, and 6.00-29.80% Al_2O_3. Composition of the natural slags was 34.16-48.56% CaO, 33.44-35.40% SiO_2, 5.67-20.12% Al_2O_3, 2.18-5.40% CaS, 0.84-4.65% MgO, 0.19-6.94% MnO and 0.64-0.97% FeO. Viscosity was determined at 1600°, 1550°, 1500° and 1400° C. CaS was added in amounts of 0, 3, 5, 7, 9 and 11%. The viscosity of synthetic slags having $SiO_2/CaO = 0.7\text{-}0.8$ and $(SiO_2 + Al_2O_3)/CaO = 0.8\text{-}0.9$ is raised by addition of CaS. Up to 5% CaS changes the viscosity only slightly, but further additions increase it sharply. Addition of CaS to natural slags also increases the viscosity, but the relationship could not be derived because the curves had maximum and minimum values. A maximum viscosity of 19-20 poises was obtained at 10-11% CaS. The viscosity of synthetic slags with $SiO_2/CaO = 0.8$ and $(SiO_2 + Al_2O_3)/CaO = 1.0\text{-}1.20$ is raised by the addition of CaS. A maximum of 11 poises at 1500° C. and 20 poises at 1400° C. was observed for 9-10% CaS. A somewhat smaller viscosity rise was found on adding CaS to slags with $SiO_2/CaO = 0.85\text{-}0.90$ and $(SiO_2 + Al_2O_3)/CaO = 0.75\text{-}0.80$. For slags with $SiO_2/CaO = 0.6\text{-}0.7$ and $(SiO_2 + Al_2O_3)/CaO = 1.0\text{-}1.2$, the viscosity rises sharply from 4% CaS up, but at 10-11% CaS it remains almost constant. MnO and MgO decrease the viscosity. Addition of CaS lowers the melting point but the drop is not proportional to the amount of CaS added. BZK (2a)

Influence of Different Slag-Forming Materials on the Viscosity of Blast Furnace Slag (Einfluss verschiedener Schlackenbildner auf den Flüssigkeitsgrad der Hochofenschlacke) F. HARTMANN. *Stahl u. Eisen*, Vol. 58, Sept. 22, 1938, pp. 1029-1033. Original research. The viscosity of various blast furnace slags was determined by the Morgules method in which an alumina cylinder suspended from a wire is immersed in the molten slag contained in a crucible; as the latter is rotated at constant speed, viscosity is indicated by the torque of the wire. The softening range of the slags was also observed and an evaluation of the slags from the practical standpoint attempted. The effect of the components CaO, MgO, SiO_2, Al_2O_3, TiO_2, ZnO, ZrO_2, B_2O_3, CaF_2, K_2O and Na_2O was determined. The results are shown in iso-viscosity curves for different temperatures and compositions. SE (2a)

Physico-chemical Principles of Sintering Krivoi Rog Iron Ores. S. ROSTOVTSEV. *Teoria i Pract. Met.*, No. 6, 1938, pp. 3-9. In Russian. A wide range of sintering mixtures was studied microscopically and chemically. With ores carrying 8-10% SiO_2 and a fuel content of 4.5-5.5%, only ¼-⅓ of the SiO_2 present forms Fe silicate, so that the high reducibility of the ore is retained. The Fe_2SiO_4 reaction is reversible and the silicate decomposes partially under oxidizing conditions. Fuel particles larger than 3 mm. are disadvantageous, particularly in sintering poor ores. Ore fines also exert a detrimental action, particularly with poorer ores, of which fines less than 0.5 mm. should be excluded. Partial fusion of the sinter is required, but excessive fusion lowers the quality of the sinter. (2a)

Properties of Krivorog Agglomerate and Their Effect on Blast Furnace Operation. I. DAIKHES. *Stal*, Vol. 8, Apr. 1938, pp. 4-11. In Russian. Practical. The use of 45-66% agglomerate in the ore charge increased production from 929 to 1081 tons per day, increased the proportion of directly reduced Fe from 56 to 62% and decreased coke consumption. Best results were obtained with an agglomerate containing 25% FeO. HWR (2a)

The Steel-tube Hot Blast Stoves of the Pilsudski Works at Chorzow (Die neuere Entwicklung auf dem Gebiete der feuerfesten Sondersteine) W. KUCZEWSKI. *Stahl u. Eisen*, Vol. 58, Oct. 6, 1938, pp. 1086-1089. Practical. A new blast furnace with steel tube hot blast stoves has been in operation at the Pilsudski works at Chorzow. Operating results indicate the steel tube hot blast stoves to be very satisfactory. SE (2a)

Rotary Stuerzelberg Furnace Produces High Grade Iron. *Iron Age,* Vol. 142, Sept. 1, 1938, pp. 29-30. Practical description of process used in producing clean molten Fe in rotary furnace, using calcined pyrites from H_2SO_4 plant, and either coke, pitcoal or lignite as fuel. The unit, developed as a low-cost producer of pig Fe, using the same grades of ore and coke, cannot compete with a blast furnace because capacity of the rotary furnace is small and economy is handicapped by overhead cost and amortization. On the other hand, the Stuerzelberg furnace is very efficient for producing small quantities of Fe. Advantages of this process over the Renn process frequently used in Europe are cited.

VSP (2a)

Reasons for Short Life of Blast Furnace Slag Pots. A. G. KALASHNIKOV. *Teoria i Prac. Met.,* No. 6, 1938, pp. 45-46. In Russian. Research. Average life of pots furnished by 1 Russian plant is 10 days-1 month, though other plants can furnish pots lasting from 6 months to about 1 yr. All of them fail by cracking. Microscopic and chemical study showed their C and Mn contents to be the same, 3.4 and 0.5%, respectively, but Si varied in the range 1.36-2.53%, which was reflected in the size and distribution of graphite flakes. Too high Si content was held as the cause of cracking. To prevent it, a composition of 3.2-3.4% C, 1.2-1.4% Si and 0.6-0.7% Mn is recommended. (2a)

Refining Pig Iron with Furnace Dust. YA. SMOLYANITSKII & A. SMOLYANITSKII. *Stal,* Vol 8, Apr. 1938, pp. 11-17. In Russian. Practical. While tapping into a ladle, 2000-2500 kg. blast furnace dust per 50 tons of pig Fe was added on the spout or in the ladle. The reaction of the metal with the Fe_3O_4 in the dust decreased Si, Mn, S and C. The average analysis before and after adding the dust was C: before 4.30%, and after 3.91%; Si: 1.08% and 0.71%; Mn: 2.54% and 2.06%; and S: 0.059% and 0.038%. Increased production of 2.55% and higher quality pig Fe gave a saving of 94,500 rubles annually per blast furnace.

Blast Furnace Department at the Broken Hill Assoc. Smelters Proprietary, Ltd., Port Pirie, South Australia. Lead Smeltery Practice at the Broken Hill Assoc. Smelters Proprietary, Ltd., Port Pirie, 1937. J. C. HUGHES. *Proc. Australasian Inst. Mining Met.* No. 107, Sept. 30, 1937, pp. 157-187. The blast furnaces, their auxiliary equipment and current practice are described. The charge consists of 6600 lbs. sinter, 200 lbs. slag skulls, 200 lbs. Pb dross, and 760 lbs. coke. Sinter analyzes 42.8 Pb, 9.4 SiO_2, 13.7 FeO, 3.0 MnO, 8.0 CaO, 9.4 Zn and 2.0% S. Skulls analyze 7.0 Pb, 21.0 SiO_2, 26.4 FeO, 2.4 MnO, 9.9 CaO, 3.1 Al_2O_3, 16.0 Zn, 4.1 S and 1.8% Cu; they are added to recover their values, dilute Zn in new slag and, because of high melting point, prevent fusion in the upper part of the furnace. The Pb dross contains 71.6 Pb and 8.8% Zn. ZnO is the chief factor tending to form accretions. Typical slag analysis is 21.0 SiO_2, 27.8 FeO, 5.4 MnO, 13.5 CaO, 5.8 Al_2O_3, 21.0 ZnO, 1.3 S, 2.0% Pb and 0.25 oz. Ag. Fume analyzes 62.0 Pb, 0.2 Cu, 13.5 Zn, 5.5 S, 0.53 As, 0.075 Sb, 2.71 Cd, 4.9% Cl, and 1.0 oz./ton Ag. The sludge, made from the fume, is filtered, the residues going into the sinter and $CdCO_3$ being precipitated from the filtrate with soda ash. The precipitate assays 0.08 Pb, 8.24 Zn, 52.67 Cd, and 0.18% Cl. AHE (2b)

Refining Processes at the Broken Hill Assoc. Smelters Proprietary, Ltd., Port Pirie, South Australia. C. G. PAIN. *Proc. Australasian Inst. Mining Met.* No. 107, Sept. 30, 1937, pp. 189-204. Descriptive. Bullion assays 0.004 Cu, 0.24 As and 0.80% Sb; 48.6 oz. Ag and 0.049 oz./ton Au. As and Sb are removed in a softening furnace; the bullion assays 0.004 Cu, 0.001 As, 0.020% Sb; and 53.4 oz./ton Ag. Ag and Au are removed by Zn to give Pb containing 0.54 Zn, 0.0005 Cu and 0.020% Sb; this is dezinced by oxidation. Sb slag from the softener containing 0.003 Cu, 3.0 As, 9.0 Sb, and 78.0% Pb is enriched to 22% Sb and shipped. Slag from the dezincing furnace is returned to the blast furnaces. The liquid Ag-Au-Zn alloy from the desilvering kettle (16 Pb and 65% Zn; 5000 oz. Ag and 5 oz./ton Au) is retorted and the Zn re-used. The Doré Ag is electrolytically parted by the Balbach-Thum process to 999.8 fineness. Au is purified by the Miller process to 990 fine. AHE (2b)

Reduction of Nickel Oxides by Means of Carbon Monoxide. D. P. BOGATSKII. *Metallurg,* Vol. 13, Jan. 1938, pp. 84-90. In Russian. Original research. Ni_2O_3 was obtained by heating $NiNO_3$ to constant weight at 600° and NiO by reducing Ni_2O_3 at 115-120° with H. Reduction of Ni_2O_3 starts at 120-122° and NiO at 344-346°. Reduction was studied for 1, 2, 3, and 4 hrs. at 100, 200, 300, 350, 400, 500, 600, 700 and 800°. Also, for 1 hr. at 250° and at 900° for 1 and 2 hrs. Complete reduction to NiO occurs in 1 hr. at 225°. The complete reduction of Ni oxides with CO is accomplished in 1 hr. at 900°. (See also *Metals and Alloys,* Vol. 8, Dec. 1937, p. MA 726L/9. BZK (2b)

Electrolytic Manganese. S. M. SHELTON, M. B. ROYER & A. P. TOWNE. *U. S. Bur. Mines Rept. of Investigations* No. 3406, July 1938, pp. 3-16. A pilot plant to produce 15 lbs./day of electrolytic Mn and its operation are described in detail. The ore used analyzed 31.10 Mn, 0.68 Fe, 17.38 SiO_2, 0.09 $CaCO_3$, 3.56 $MgCO_3$, 1.54 Pb, 0.15 As, 0.14% Cu, trace of Ni and Co. Highly efficient leaching may be expected from a porous ore ground to —10 mesh; a dense ore requires finer grinding. No improvements were found over the methods described by Clevenger and Carron for reducing MnO_2 to MnO. Equipment for leaching and electrolysis is similar to that required for a low acid electrolytic Zn plant. Practically the same impurities must be removed to the same degree from the electrolyte. Simple cloth diaphragms are required. Assuming equal current densities, the number of cells or total cathode area required for electrolytic Mn, with respect to electrolytic Zn, is inversely proportional to the respective current efficiencies for the same capacity. Power required for electrolysis was about 3.6 kw.-hr./lb. of metal. Reagents for purification depend on impurities to be removed. The major reagent cost is for removal of Co and Ni. For the experimental plant, reagent consumption/100 lbs. electrolytic Mn was $FeSO_4$ 1.7, Na ethyl xanthate 2.0 and K pentasol xanthate 1.3 lbs. Leaching reagent (spent electrolyte containing 2½-3% H_2SO_4) is regenerated. Loss of acid depends largely on acid-soluble alkali metals in the ore; for the ore used it was approximately 20 lbs. H_2SO_4/100 lbs. Mn. Not more than 1 lb. SO_2/100 lbs. Mn was added to the catholyte feed tank to condition the electrolyte. The sulfite ion oxidizes to SO_4 and partly replaces leaching losses. After the "break-in" period, only S and NH_3 will be needed to replace losses in leaching and electrolysis. High concentration of $(NH_4)_2SO_4$ was used for 2 reasons: (1) With $(NH_4)_2SO_4$ concentration 100 g./l. or greater in the almost pure solution, there was less resolution of deposited metal and (2) high metal recovery necessitates low $MnSO_4$ concentration in the catholyte chamber; $MnSO_4$ is a relatively poor conductor of electricity, particularly at low concentrations; high $(NH_4)_2SO_4$ serves to reduce ohmic resistance and provides lower cell voltage and lower power consumption. $MnSO_4$ in the catholyte feed was limited to less than 70 g./l. in order to limit H_2SO_4 concentration of the anolyte and better protect the cloth diaphragms. Current efficiency was approximately 50%, as much as 70% for 24 hrs., and increased with continued operation. It is largely a function of electrolyte purity.

AHE (2b)

The Scientific Fundamentals of Tin Smelting III (Die wissenschaftlichen Grundlagen der Zinnverhütung III) JOSEF KLÄRDING. *Metall u. Erz,* Vol. 34, No. 21, 1937, pp. 556-558; No. 22, pp. 580-584. Original research. Chemically pure SnO was mixed with 25% of coke dust, pine soot, semi-coke, charcoal or brown coal, and heated in an atmosphere of N_2 in an electric furnace to 700°, 800°, 850° and 900° C. Coke dust did not react until 850° C., whereas the other materials gave good reductions at 800° C. Reaction rate increased with increased amount of reducing agent. The rate and temperature of reaction depend on the amount and composition of volatile matter given off. Previous degassing of the fuel at 1100° C. diminishes the reducing action. For Part II, see *Metals and Alloys,* Vol. 9, Jan. 1938, p. MA 8 R/6. PCR (2b)

Some Reductions of Columbium Pentoxide. N. KH. ABRIKOSOV. *Metallurg.* Vol. 13, Apr. 1938, pp. 9-14. In Russian. Original research. Reduction of Cb_2O_5 by H_2 or CO consumes so much reducing agent, even above 1500° C., that the process is of no practical value. Reduction with C at atmospheric pressure is possible above 1660° C.; lower temperatures require a vacuum. Below 1530° C., the finely ground C and Cb_2O_5 must be thoroughly mixed because the reduction takes place by the direct interaction of solid phases. Reduction with atomic H goes to completion without difficulty and requires no excess of H. BZK (2b)

Investigation of the Equilibrium of the Reaction NiO + CO $\rightleftarrows$ Ni + CO_2. D. P. BOGATSKII. *Metallurg,* Vol. 13, Feb. 1938, pp. 18-24. In Russian. Research. The equilibrium NiO + CO $\rightleftarrows$ Ni + CO_2 was approached both by reducing NiO and by oxidizing Ni. For the interval 500°-1100° C., K_p changed from 554.6 to 57.2 according to $\log K_p = \frac{1735.1}{T} + 0.49935$. Other values obtained were: $\Delta H_{298} = 58301.6$ cal., $\Delta F°_{298} = 9352.85$ cal., and $S°_{298} = 11.31$ cal./degree. BZK (2b)

Theoretical Considerations in the Methods for Electrolysis of Fused Salts (De teoretiska grunderna för de smältelektrolytiska förfarandena) GÖSTA ANGEL. *Tek. Tid.,* Vol. 68, Oct. 8, 1938 (Section *Bergsvetenskap*) pp. 73-79. A theoretical discussion of the electrolysis of fused salts of Al, Mg, Na, Li, K, Ca, Ba, Sr, Ce, and Be. Discusses conductivity of the pure salts and salt mixtures, decomposition voltage, electrode potentials, polarization and anodic effect, ampere efficiency, electrode arrangement and materials, and diaphragms. A comparison between pure electrothermic and electrolytic methods generally favors the latter. BHS (2b)

Heating Air for Foundries in Steel Recuperators. ALFRED SCHACK. *Hutnik,* Vol. 10, No. 6, 1938, pp. 313-320. In Polish. Review. A discussion of the heat value of fuel gases, depending upon the temperature of the air used, shows possible fuel economy of 25% with preheated air. Steel recuperators do not accumulate heat and permit use of high pressure burners that effect thorough mixing of the gas and air. A description of recuperative furnaces in use for 3-5 yrs. and capable of heating 1,500-25,000 cubic meters air per hr. to temperatures up to 850° C. is given. The heat efficiency reaches 85%. Service life is not shorter than that of Cowper furnaces. The highest temperature of the tubes is 1050° C., well within the safety limit. Fuels of low heat value can be used. JGT (3)

The Solution of Oxygen in Liquid Metals (Ueber die Sauerstoffaufnahme in flussigen Metallen) WERNER LANGE. *Z. Metallkunde,* Vol. 30, Aug. 1938, pp. 274-276. Experimental. A jet of O was blown onto a molten bath of Cu, so that the oxidation reaction rate was not controlled by the rate of diffusion of O to the gas metal surface. The rise in temperature of the melt was followed as a measure of the rate of the reaction. Under these circumstances the diffusion of O in the melt controls the rate of oxidation until the metal becomes saturated with gas. The same effects were noted with other metals which have an affinity for O, Pb, Sn, Ni, Mn and Fe, but no temperature rise occurred with Ag. GD (3)

Risers or Gates for Some Special Non-ferrous and Alloyed and High Test Iron Castings. C. BRISBOIS & A. E. CARTWRIGHT. *Trans. Am. Foundrymen's Assoc.,* Vol. 46, Sept. 1938, pp. 219-248. Experimental. Pouring castings directly through risers was found successful for many types of castings, of both non-ferrous metals and high test and alloy cast irons. The experiments were conducted on castings weighing from a few ounces to those weighing 2 tons. As the basic form of feeding head, a straight-sided, round-shouldered, short-necked feeding head was adopted. In the authors' plant probably about 50% of the jobs eligible for this method of molding are so produced. CEJ (3)

Material for Centrifugal Casting Mold (Werkstoff für Schleudergusskokille) *Giessereipraxis,* Vol. 59, Aug. 14, 1938, pp. 333-334. To obtain proper cooling conditions, special bronzes were developed as material for centrifugal molds, containing 3-11% Al and 15-5% Ni + Fe. For Fe molds, Al additions of from 1 to 10% are advised. When first used, the interior faces of such molds will be covered with a thin skin of Al_2O_3 that retards heat transition from molten metal to mold, preventing excessive stresses in mold and guaranteeing more uniform cooling conditions, thus increasing mold durability. Method for Increasing Roof Life of Open Hearth Furnaces. A. GADBIN & I. WINESTEIN, *Teoria i Pract. Met.,* No. 6, 1938, pp. 17-19. In Russian. Cooling effect of the charging doors shifts the major portion of hot gas current towards the back wall of the furnace and through the rear downtake. This greatly concentrates the wear, so that the roof over the rear downtake fails far ahead of the roof as a whole. Original strengthening of these portions of the roof or patching them does not solve the problem completely. Front downtakes of 4 stationary furnaces were made 1100 x 2000 mm. in place of the original 1000 x 2000 mm.; the latter dimensions were kept for the rear downtakes. Without any changes in practice, the number of heats which could be obtained in these furnaces before roof failure were: 243 (stopped before failure), 331, 204 (stopped before failure) and 270, in place of the original 190, 147, 166 and 135 heats. This modification of downtakes also slightly increased the life of the front walls. (3a)

The Fundamentals of the Desulphurization of Pig Iron with Sodium Carbonate and Sodium Silicates (Die Grundlagen der Entschwefelung des Roheisens mit Soda und Natiumsilikaten) F. KÖRBER &. W. OELSEN. *Stahl u. Eisen,* Vol. 58, Aug. 25, 1938, pp. 905-914; Sept. 1, 1938, pp. 943-949. Original research by means of extensive laboratory studies and plant tests. Na_2CO_3 alone is a superior desulphurizer in the absence of SiO_2 or Si in the pig Fe. The Na_2S thus formed is stable at 1300-1400° C. in the presence of the melt, and does not require $Na_2O.SiO_2$ to keep it dissolved in the slag. Even at low S contents, however, FeS tends to separate out of the melt, so that some desulphurization may occur without the formation of Na_2S. No other reducing agent than C is necessary to promote desulphurization. The presence of SiO_2 hinders desulphurization and results in a higher S content because part of the Na in the Na_2CO_3 is consumed in forming $Na_2O.SiO_2$. Nevertheless, the $Na_2O.SiO_2$ has some desulphurizing action since it may react to form some Na_2S, and because it tends to dissolve out FeS from the bath. Upon the formation of highly basic sulphide-rich slags, and as a result of the reducing action of the C, strong deoxidation ensues; with viscous acid slags the deoxidation is weaker. A subsequent addition of SiO_2 to a reduced basic desulphurizing slag has the strongest deoxidizing effect and with sufficient excess SiO_2 may even result in a Si reduction by means of Na_2S. In this case S pickup is less than when SiO_2 is originally present in the slag. The addition of oxidizers or undecomposed Na_2CO_3, as well as a large excess of SiO_2, will cause a S pickup. The desulphurizing action of $Na_2O.SiO_2$ increases at higher temperatures. SE (3a)

Content of Ferrous Oxide in Open Hearth Metal Depending on the Basicity of the Slags and their Oxidation Value. P. N. IVANOV. *Metallurg,* Vol. 13, Apr. 1938, pp. 21-30. In Russian. Original research. The use of slags of high basicity raises the FeO in the metal; the FeO increases much faster than CaO/SiO_2. The increased FeO is due to a low Mn concentration and to the increased partial pressure of the CO, which is dissolved in the metal under the influence of the highly viscous slags. The failure of the slags to remove the S and P may be partly compensated by the addition of bauxite to raise their fluidity. Differences between the theoretical and experimental FeO are due to the fact that the analytical determination of FeO gives only the FeO that is in equilibrium with C and other elements. The non-equilibrium FeO escapes fixation because of the high speed of reaction in the homogeneous liquid phase, and has no practical effect upon the quality of the metal. BZK (3a)

Melting of Gray Iron in the Electric Furnace (Ueber das Erschmelzen von Grauguss im Elektroofen) O. GLASER. *Giesserei,* Vol. 25, Sept. 9, 1938, pp. 454-457. The electric furnace is particularly advantageous for the production of high-grade cast Fe of fine-lamellar pearlite and uniformly distributed fine-flake graphite. The former is obtained by controlling the composition and rate of solidification; the latter depends on mass, as well as on superheating of the melt. The most popular method in the electric furnace is to make a "synthetic" cast Fe from a liquid charge of low C content that is increased in the furnace by addition of charcoal, pieces of electrode C, coke, etc.; section of the furnace and size of the added pieces also have a certain influence on carburization. The different melting methods and the improvement of the mechanical properties of cast Fe by heat treatment are discussed. Examples of castings and their properties are described. 9 references, Ha (3a)

Use of Chromium-nickel and Chromium-molybdenum Scrap in Acid Electric Arc Furnaces. YU. SHULTE. *Stal,* Vol. 8, Apr. 1938, pp. 56-62. In Russian. Practical. The results of 850 heats corresponding to S.A.E. 3415 and X4130 steels are summarized. The charge consisted entirely of Cr-Ni and Cr-Mo steel scrap. The slag during the oxidation period contained approximately 50% SiO_2, 25% FeO, 15% MnO and 7% Cr_2O_3. By maintaining a high temperature during the oxidation period, Cr oxides in the slag and metal are reduced by C. The macrostructure and mechanical properties of the acid steel were superior to basic electric steel and consumption of ferro-chrome was reduced 65%, Ni 75% and ferro-molybdenum 75%. HWR (3a)

CASTING PERFECT PLATES WITH PURITE

For thirteen years Steinway has used PURITE in making strong, light-weight piano plates

The Steinway Piano, famous for years as "the Instrument of the Immortals", requires a frame light in weight yet strong enough to stand without distortion a tension of 36,000 to 50,000 lbs. The Steinway people say, "The vibrating quality of our pianos, which is so highly esteemed, is the result, to no small extent, of the use of these light piano plates."

These plates are made in their own foundry, to rigid specifications. The cupola is fluxed with 3 lbs. of Purite per ton of metal, which improves combustion, and insures clean strong castings. This practice has proved of great advantage in producing the perfect plates so essential in maintaining Steinway quality.

Steinway's is only one of many tough and unusual problems solved with the aid of Purite. Right now there are jobs in *your* foundry which can be done better with the use of Purite.

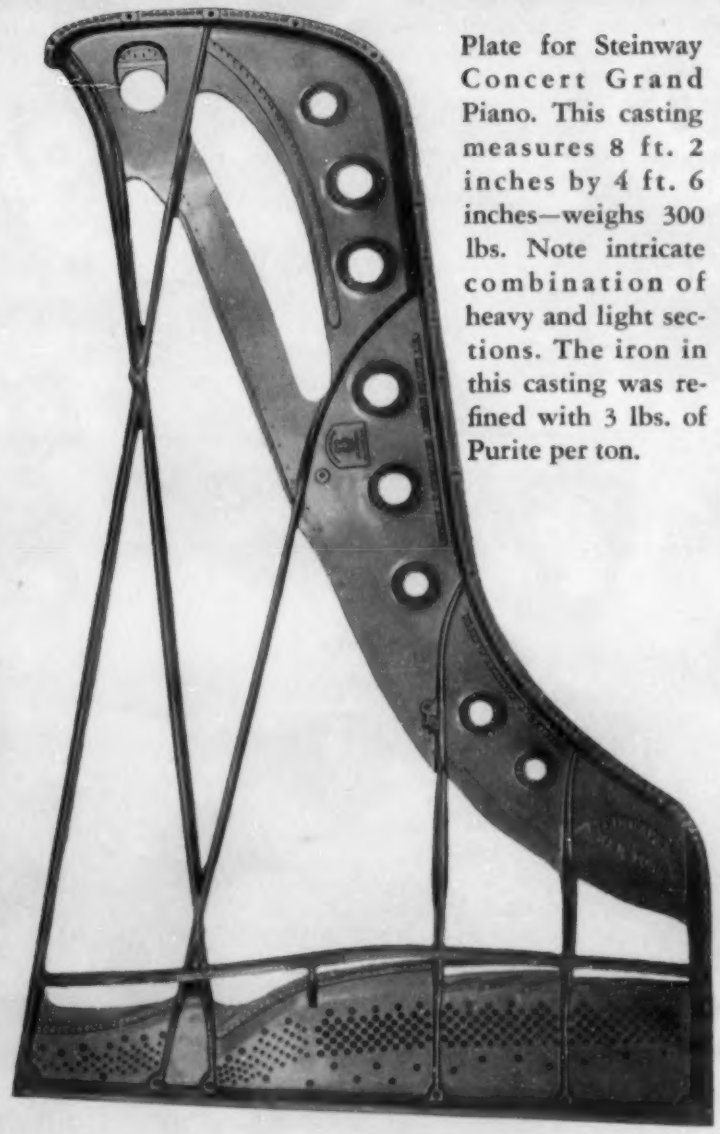

Plate for Steinway Concert Grand Piano. This casting measures 8 ft. 2 inches by 4 ft. 6 inches—weighs 300 lbs. Note intricate combination of heavy and light sections. The iron in this casting was refined with 3 lbs. of Purite per ton.

Open-hearth Control. M. J. BRADLEY (Leeds & Northrup Co.) *Steel,* Vol. 103, Aug. 29, 1938, pp. 34-36, 60. Review. Discusses change in methods of operating open-hearth furnaces during recent years, and benefits derived from application of automatic control equipment. As a result, many furnaces produce at present a better quality of steel at about half the average of 6,400,000 B. t. u. used to produce a ton of ingots in 1928-1929. Some furnaces built during past year and furnished with means for controlling pressure, reversal, roof temperature, and fuel-air ratio are using several 100,000 B. t. u. less per ton even than above figure. Comparison of before-and-after costs of operation on a number of installations using various combinations of control instruments shows average savings of 9% in tonnage, 12% in refractories and 8% in fuel. MS (3a)

"Short Cycle" Pearlitic Malleable Iron (Ueber perlitischen Schnelltemperguss) R. GNADE, E. PIWOWARSKI & W. FELIX. *Giesserei,* Vol. 25, Sept. 23, 1938, pp. 469-473. Research. By systematically changing C-, Si- and Mn-content, the composition of a material that can be malleablized in a very short time, with a principally pearlitic structure independent of rate of cooling, was found. The composition was 2.4% C, 0.6-0.7% Si, 0.7-0.8% Mn; the best cooling rate was 80°-100°/hr. Tensile strength 85,000-100,000 lbs./in.^{2}; elastic limit 57,000 lbs./in.^{2}; and elongation 1.5-2%. Melts with up to 1.5% Ni showed, in spite of finer temper C, not much better mechanical properties. Ha (3a)

Cooperation between Founder, Designer and Shopman (Die Zusammenarbeit zwischen Giesser, Konstrukteur und Bearbeitungsfachmann) H. JUNGBLUTH. *Giesserei,* Vol. 25, Sept. 9, 1938, pp. 442-447. Cooperation on the basis of selecting the correct material for a given purpose, designing the piece correctly so that the foundry can turn out a sound casting, and also designing it correctly from the machining point of view, is emphasized, and proper procedures are illustrated by examples. 7 references are given for selection of material, 32 for design for foundry purposes and 2 for machining. Ha (3a)

Conditions Necessary for the Production of High Quality Medium Carbon Steel. A. DUDAR. *Stal,* Vol. 8, Apr. 1938, pp. 18-23. In Russian. Practical. A study of 1000 open hearth heats showed that the quality of the steel was best if (1) the oxidation period lasted at least 2 hrs.; (2) the average rate of C oxidation was 0.004-0.006%/min., decreasing to 0.002-0.004% at the end of the oxidation period; and (3) if the Mn content did not drop below 0.30% during the heat. Melting and Casting—Common Difficulties and Their Elimination by Modern European Practice. Part I. EDMUND R. THEWS &. W. FROELICH. *Can. Metals Met. Inds.,* Vol. 1, July 1938, pp. 198-200. Review. The difficulties in the melting and casting of non-ferrous alloys and some successful and unsuccessful means of elimination are discussed. Alloys discussed include: Common brass, bronze sand castings, gunmetal, phosphor bronzes and Sn bronzes. **Part II.** *Ibid.,* Sept. 1938, pp. 249-250. High-Ni brasses subjected to a superheating temperature of about 210° F. above casting temperature under a layer of charcoal were definitely weaker than the same metal superheated beneath a flux cover. This condition is due to the presence of excess of C. Most of the failures obtained with Ni brass castings are due entirely to faulty methods of melting and alloying. Remelting of gunmetals results in even more beneficial results than are obtained in remelting high-Ni brasses. Correct packing of the different parts of the charge, a minimum of stirring, and the renewal of the C cover at not too frequent intervals are important features of Ni brass remelting. WHB (3b)

Sand Control in Non-ferrous Foundry Practice. G. K. EGGLESTON. *Foundry Trade J.,* Vol. 59, Sept. 29, 1938, pp. 236-238. Descriptive. Grain distribution, rather than average grain size, is the governing factor of casting finish. The permeability is dependent upon the per cent of voids and the surface area of the grains. The strength and durability of a sand depends upon the species of clay and the size of the particles, not the total clay content. The re-use of floor sweepings by screening and removal of fines can greatly reduce the quantity of new sand used, in some cases about 50%. AIK (3b)

Experimental Production of Oxygen-free Copper by Remelting with Boron Slags. M. P. SLAVINSKII & M. SH. KHASKHOZEV. *Metallurg,* Vol. 13, Apr. 1938, pp. 15-20. In Russian. Practical. The boron slag was prepared by melting a powdered mixture of 4-5% Mg and 95-96% $Na_2B_4O_7$. About 2-4% of this slag is necessary to completely deoxidize Cu that contains a small amount of O_2. To obtain O-free Cu, the metal should be superheated to 1300°-1350° C., be in good contact with the slag, and be isolated from the air during pouring. BZK (3b)

MANGANESE ORE
METALLURGICAL AND DIOXIDE GRADES

Direct from newly discovered deposits in Australia.

Non-ferrous Castings. The Proper Use of Runners and Risers. F. DUNLEAVY. *Metal. Ind., London,* Vol. 53, Sept. 23, 1938, pp. 294-302. Discussion of several difficult problems encountered in casting bronzes and Al. In casting an Al plate 3 ft. 6 in. by 3 ft. 1 in. by 1½ in., good castings were produced only after 2 risers were put in the center of the plate. A large amount of heat is lost in the ordinary riser or feeder by contact with the atmosphere and sand. By pouring small P-bronze castings in a rather unorthodox manner (4 to a feeder) the hottest metal is found just at the spot where it is required, at the joint of the runner and casting. If these 4 castings were run in the usual manner, considerable waste would have been involved. The temperature would have had to be very closely controlled because, if too low, the block casting would be drawn at the runner and, if too high, a very spongy patch would be expected on top of the casting. Mn-bronze or high tensile brass demand special treatment when cutting runners or risers. They have the habit of drawing in the most unlikely places. Very often running in the top part instead of the bottom may eliminate this defect. Wet sand or too liberal use of the swab will cause bad patches in this area. Casting at too high temperature or poor design will cause these defects. Dross in castings is usually due to poorly designed runners. All risers for Mn-bronze must be cut so that the neck of the riser is as short as possible, otherwise a badly drawn place can be expected. A long stream of metal must be avoided in pouring, or scummy metal will be formed. No attempt should be made to force the metal in the mold. In casting Al it is advisable to use a number of wide and thin ingates in preference to one large one. The advantage of this is that the casting temperature can be lowered considerably, and solidification commences almost immediately. RWB (3b) 1 2 3 4

Production and Properties of Age Hardenable 5% Nickel-bronze Castings. T. E. KIHLGREN (Internat. Nickel Co., Inc.) *Trans. Am. Foundrymen's Association,* Vol. 46, Sept. 1938, pp. 41-59. Practical. The properties and foundry production of an age hardenable Ni bronze of moderate cost and broad utility are presented; the composition is 88% Cu, 5% Ni, 5% Sn and 2% Zn. The mixture possesses physical properties somewhat superior to those normally obtained for 88-10-2 bronze in the "as-cast" condition and, in addition, can be age hardened to secure the following range of properties: 70,000-90,000 lbs./in.^{2} tensile strength, 50,000-74,000 lbs./in.^{2} yield point, 25-5% elongation, and 140-200 Brinell hardness. The effect of modifications of the normally employed heat treatment are discussed. Pb is a highly objectionable impurity, and as little as 0.05% will seriously retard age hardening and also cause hot cracking if the castings are cooled rapidly from the 1400° F. "solution treatment." Si retards aging, but the effect of small amounts of Si (0.05-0.10%) can be neutralized to a certain extent by a moderate increase in the aging temperature and in the Ni content (to 5.5%). The effects of other impurities are briefly discussed. The foundry procedure recommended for castings to be age hardened differs from that considered good practice in 88-10-2 bronze, chiefly in the oxidation of the Cu-Ni melt with cuprous oxide (or other suitable oxides) and a subsequent reduction with P, prior to the addition of remelt and the introduction of Sn and Zn. Where heat treatment is not contemplated, or maximum response to heat treatment is not required, the oxidation treatment may be omitted, and melting merely carried out in a moderately oxidizing atmosphere. The oxidation treatment, however, has been found definitely to increase the response to age hardening and to be generally helpful. CEJ (3b) 5 6 7

Die Castings Gain Ground in Hardware Production. HERBERT CHASE. *Iron Age,* Vol. 142, July 21, 1938, pp. 33-36; Aug. 4, 1938, pp. 42-44. Practical discussion of die casting technique used by Yale & Towne Mfg. Co. The first instalment considers chiefly the intricate dies employed in multiple cavity work. Sections as thin as 0.015 in. are cast between movable cores in some instances. Wherever feasible, several parts of the same assembly are produced in the same die; this practice sometimes yields as many as 20 small castings in a single "shot" of the casting machine. All dies are hardened to maintain the degree of accuracy required when parts have relative motion. The second instalment deals with subsequent machining operations on small, cored lock plugs. Unusually well illustrated. VSP + FPP (3b) 8 9

"Frostiness" in Plumbers' Solder. C. H. S. TUPHOLME. *Can. Metals Met. Inds.,* Vol. 1, Oct. 1938, p. 284. "Frostiness," often associated with inferior metal, can be produced on the surface of a bar of otherwise good quality solder by casting into an overheated mold or by the presence of Zn, Al or Cd. This effects a coarser structure than that produced by pouring into a cool mold. Examination of test joints and the results of pressure tests show no evidence of poorer quality for the coarse grained solder. There is no connection between what the plumber considers the working properties of the solder and the quality of the joint. WHB (3b) 10

New type-1½. Floor attached to shell, tilts with furnace.

USE them for efficient melting and refining of all kinds of ferrous materials by either basic or acid process—including alloy, tool and forging steels, iron and steel castings. Any capacity from ½ ton to 100 tons; removable roof, chute, machine or hand charging.

"During the summers of 1936 and 1937 we fused 54 rock samples in our Ajax-Northrup Furnace. The samples consisted of mixtures of limestone and shale and limestone and quartz. The furnace was customarily operated at 1500 C. The purpose of the fusion was to secure molten rock which was poured through a steam jet, and rock wool obtained. The results of this research were published in 'Rock Wool Resources of Kansas,' State Geological Survey of Kansas Mineral Resources Circular 5, 1937, and 'Rock Wool Resources of Kansas, Appendix,' State Geological Survey of Kansas Mineral Resources Circular 8, 1937.

"The Ajax-Northrup Furnace proved to be quite satisfactory in making this investigation. A big advantage in using this furnace was the speed at which the test would be run."

New Applications for Press Work. Part I. Replacement of Parts Now Made by Other Methods. J. D. JEVONS. *Metal Ind., London,* Vol. 53, Oct. 21, 1938, pp. 389-392. Review dealing with new applications for drawn and pressed parts. Increasing 3
application may be anticipated in all kinds of engineering components, domestic and utilitarian articles, all manner of containers, ranging from large vessels in "clad" material to collapsible tubes and tiny capsules, cowls and fairings for aircraft, panels and other members for road vehicles, and ordnance work. The replacement of the whole articles or component parts, hitherto cast, by either one piece, Cu-brazed, or welded multi-piece pressings with consequent saving in both weight and cost, is already under way. Pressed and drawn steel parts of sufficient thickness may be case 4
hardened and used to replace many parts hitherto machined from the solid. A combined inlet and exhaust manifold for a 4 cylinder automobile engine is an example of a replacement in which, although the cost of production of the built-up article may not be less than that of the casting, other advantages render the built-up pressed steel product preferable. This manifold represents a 63% weight-saving over the cast manifold, and the smooth internal surfaces and accurately-spaced and dimensioned openings increase the engine efficiency. Pressed and drawn parts can be welded 5
together, to replace heavier and more expensive methods of fabrication, often with an increase rather than a decrease in strength and rigidity, although the cost of large press tools can only be met by a guaranteed output of a large number of pressings.

Rope Wire. W. R. BLOXDORF (Macwhyte Co.) *Wire & Wire Prod.,* Vol. 13, Oct. 1938, pp. 505-515, 617. Comprehensive review. High tensile strength is not the only important quality expected of rope wire; ductility, toughness, resistance to deformation and fatigue resistance are also required. Production of satisfactory cold drawn steel wire for wire rope depends on selection of composition and raw material (wire rod); correct heat treatment; correct manipulation (cleaning, coating, baking, and subsequent cold drawing) of heat-treated material. Each of these 8
factors is discussed. Most rope wire in modern use is made from fully-killed open-hearth (acid or basic) steel, although a small amount of low-C rimmed steel is used in producing the weakest grade of rope wire. The strongest grade ("Improved Plow Steel") of rope wire contains 0.65-0.85% C and must have a tensile strength of at least 230,000 lbs./in.^{2} Coarse to medium-grained "normal" steels are preferred. Preliminary patenting of hot rolled rods before drawing is advocated, particularly if the C 9
content be over 0.55%. Patenting produces a uniform coarse-grain structure consisting of fine lamellar pearlite with a minimum of free ferrite. Direct electric resistance patenting of 0.128-in. 0.67% C stock is described. The resistance patenting produced a great improvement in fatigue strength as compared with that of wire patented in conventional gas-fired furnaces. Other properties of satisfactory rope wire are discussed. Ha + FPP (D-4a)

The Machining of Mn Steel. *Machinery (London),* Vol. 52, Sept. 22, 1938, pp. 757-762. Practical. Although the 12% Mn 10
steel has a hardness of only 180-210 Brinell after water quenching from 1050° C., special high speed steels and tool design as well as a rigid set up are necessary to avoid cold working the surface of the steel, which makes machining impossible. JZB (G-4a)

Manufacture of Large Forgings. WM. J. MERTEN. *Ind. Heating,* Vol. 5, Oct. 1938, pp. 923-928. Practical. Discusses character of steel (acid or basic open hearth) for forging ingots; type of mold; casting of ingot to avoid cold shuts, shrinkage cavity, etc.; heating for forging, and soaking pit practice; hot pressing and the individual forging operations; annealing; and testing. In the example described, the corrugated ingot was stripped from the mold at 1200° F. after 42 hrs., heated to 2200° F. for 48 hrs., then top-end-rounded and body-roughed to 58 in. The ingot was then heated to 2100° F., held in the furnace for 18 hrs., subjected to the second forging operation, heated slowly to 2200° F., held there for 20 hrs., given the third forging operation, heated at 2300° F. for 8 hrs., given the fourth forging operation, heated at 2250° F. for 8 hrs., then finish-forged. The forging was then placed in the furnace, heated at 1600° F. for 24 hrs., cooled slowly to 1300° F., reheated at 1600° F., cooled slowly to 200° F., and allowed to cool in air. Mechanical properties of samples of the finished forging were: Tensile strength, 77,500 lbs./in.^{2}; yield point, 39,000 lbs./in.^{2}; elongation in 2 in., 21-26%; reduction of area 41%. Ha + FPP (D-4a)

The Cold Deformation and Recrystallisation of Metal Crystals with Particular Reference to Alpha-iron. J. W. RODGERS. *J. Iron Steel Inst.,* Advance Copy No. 13, Oct. 1938, 17 pp. Original research. An X-ray examination of the recrystallizing properties of single crystals and polycrystals of α Fe showed that the tendency of metal crystals to recrystallize after cold deformation is greater if the deformation takes the form of compressive strains, such as cold rolling, than if it takes place in tension. A tentative theory is put forward in which the supposition is made that there are 2 types of plastic flow: (1) Easy flow along the normal glide directions, which does not change the mechanical state of the metal to any great extent; and (2) difficult flow, which takes place across the normal glide directions and causes a considerable rise in the internal energy of the metal; this is accompanied by an increased tendency to recrystallization and a considerable increase in penetration hardness. Tensile stresses promote easy flow and compressive stresses difficult flow. This theory fits in with certain experimental observations on grain growth after cold deformation. Practical applications of the theory are discussed. 7

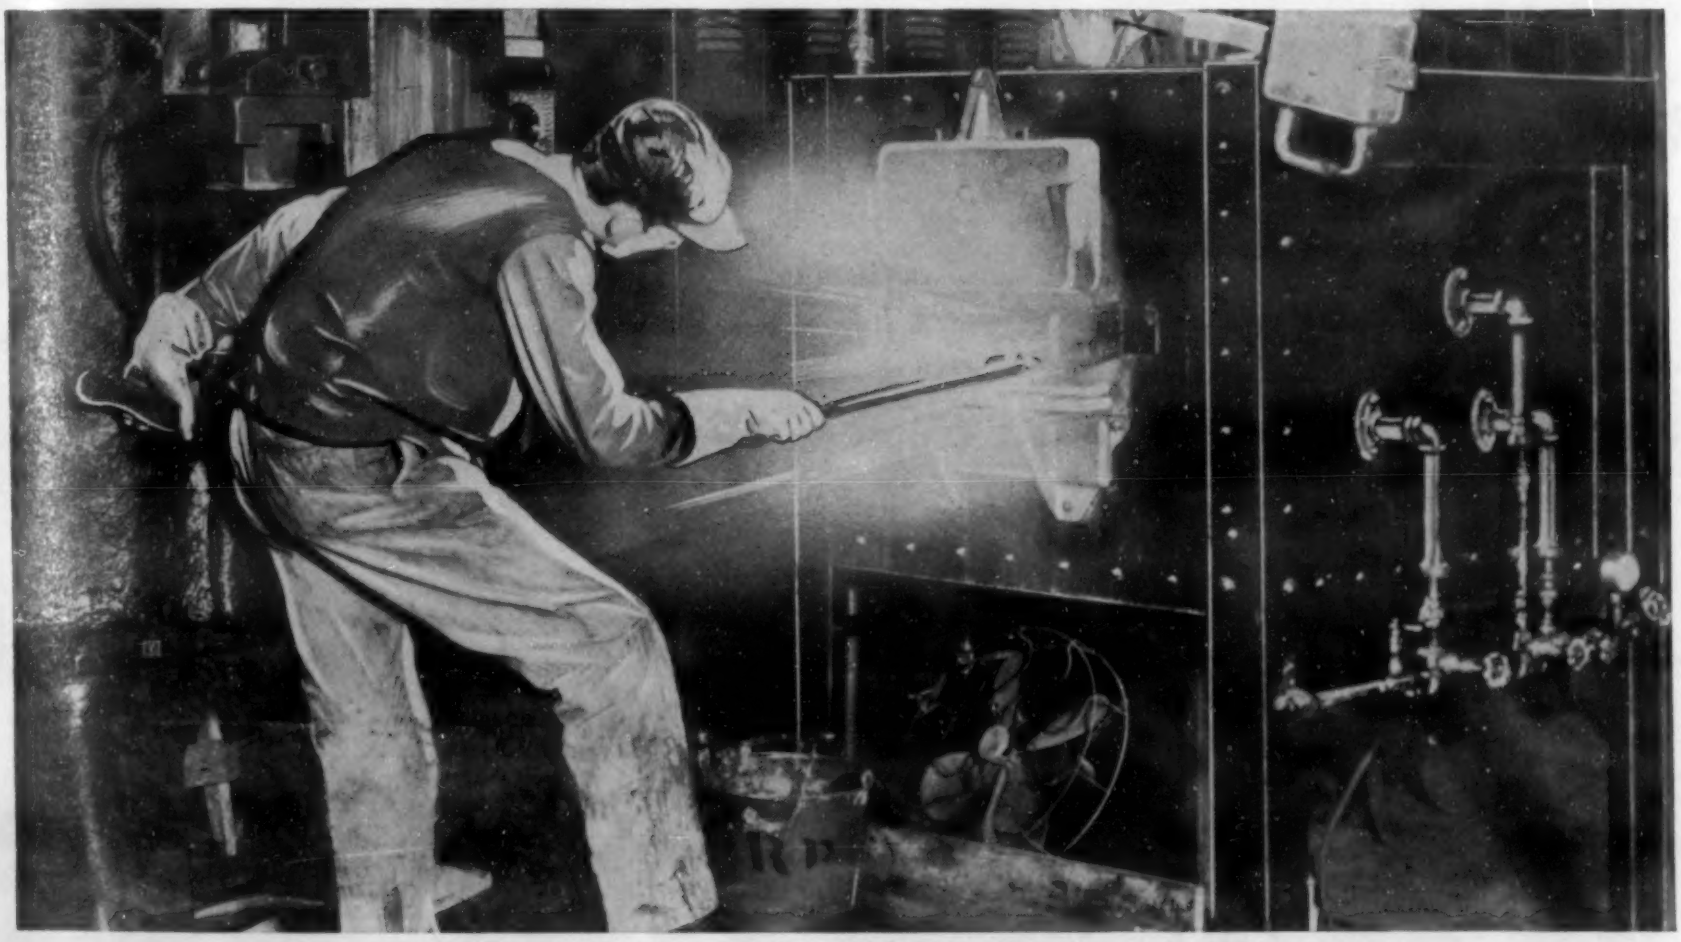
Plastic Hot and Cold Forming of Light Metals—Rolling, Forging, Pressing, Drawing (Plastische Warm- und Kaltverformung von Leichtmetallen, Walzen, Schmieden, Pressen, Ziehen) *Tech. Blätter,* Vol. 28, Sept. 25, 1938, pp. 566-568. A survey of present-day German practice of forming light metals and their respective alloys, such as Al and Al alloys, including Al and Cu clad light metal alloys. Particular points to be observed in extruding, rolling, forging, drawing and roll forming are stressed. Heating and annealing furnaces are briefly considered. GN (E-4b)

Advances of the Forged Piston (Der geschmiedete Kolben im Vordringen) ERICH KOCH. *Deut. Motor Z.,* Vol. 15, May 15, 1938, p. 172. Original research. In comparison with the cast light metal piston, forging furnishes considerably higher strength and toughness without impairing the running qualities. Microstructures of a forged duralumin type piston and of an Al-Si alloy are shown. The latter has been perfected as a forging recently. EF (D-4b)

Gas IN THE FURNACE



means finer work at the forge

The flexibility of GAS heat, and the absolute precision with which it can be controlled, make GAS the ideal fuel for all forging operations.

With GAS in the furnace, finished forgings can be held to closer dimensions . . . rejections due to overheating are lessened . . . the life of forging dies is prolonged . . . and production of forged parts steps up while unit costs come down.

Modern improvements in GAS equipment are bringing new economies for all heat treating processes which require delicate and accurate control in a narrow spread of temperature limits.

Investigate what GAS can do for <u>your</u> production —regardless of the size of your plant!

Temperature Uniformity in Combustion Chambers. M. H. MAWHINNEY. *Ind. Heating,* Vol. 5, Oct. 1938, pp. 906-913. Practical. In a previous article (see *Metals and Alloys,* Vol. 7, Dec. 1936, p. MA 584 R/10) the author demonstrated that the size of a combustion chamber should be based on a heat liberation between 7 and 10 B.t.u./ft.³ of chamber volume, and that the total port area from the chamber should be based on a maximum liberation of 400 B.t.u./in.² of port area. The relative dimensions of chamber width, length and height to obtain this volume, particularly as they affect temperature uniformity, are discussed in the present article. Minimum height should be 7½ in. for combustion chambers less than 48 in. long, and 12½ in. for chambers longer than 48 in. Burner block should be set flush with the inside of the wall to reduce the size of the hot port, which is not balanced by a similar hot area at the other end. Ports should be graduated in size from one end to the other, with largest areas at the burner end, to balance the effect of flame velocity from the burners. A graphical summary of numerous tests on furnaces of different dimensions and operating at different temperatures gives approximations for port distribution in furnaces of various designs. Furnace design should be such as to permit changing the distribution of ports with a minimum of difficulty. Ha + FPP (5)

Bright Annealing Plant. A Hood Type Electric Furnace. *Metal Ind., London,* Vol. 53, Oct. 28, 1938, pp. 421-422. Description of commercial installation. The plant is designed to handle small metal parts, particularly those requiring special treatment for magnetic properties. The parts are in a completely machined condition, and the anneal is purely to reduce their retentivity to a minimum. The plant consists of the furnace, switch gear, temperature control and ammonia dissociator. The furnace comprises a cylindrical cover, which can be raised or lowered by means of a crane, and 2 fixed bases each having a gas tight hood. Each base is used alternately, reducing the time between anneals, thus increasing the capacity. Heating elements are provided, both in the cover and the base, so that the charge, which is contained in a basket, surrounds the center heater and is heated almost entirely by direct radiation. The gas tight hoods fit closely over the center heater base and are rendered gas tight by oil seals. A "neutral" atmosphere of H_2 and N_2 is obtained from cracked ammonia and a special burner. RWB (5)

Recent Developments in the Field of Special Refractories (Die neuere Entwicklung auf dem Gebiete der feuerfesten Sondersteine) F. HARDERS. *Stahl u. Eisen,* Vol. 58, Oct. 6, 1938, pp. 1081-1085. Review. Magnesite bricks have been applied because of their resistance to temperature changes and their retention of strength at high temperatures. Recently, a porous magnesite brick has been used in highly stressed portions of open-hearth furnaces. In the U. S. the production of unburnt magnesite brick has been growing. Unburnt chrome-magnesite brick with very good properties are also produced in the U. S. Chrome-silica and chrome-alumina brick have been utilized, but so far not in Germany. Work is being done in the U. S. and Germany on magnesia-silicate brick. 31 references. SE (5)

Performance and Types of Electrically Heated Continuous Furnaces (Wirkungsweise und Bauformen elektrisch beheizter Durchlauföfen) A. SCHAU. *Elektrotech. Z.,* Vol. 59, June 2, 1938, pp. 577-580; June 9, 1938, pp. 608-611. The conditions of heat transmission in a furnace are discussed at length. A calculation of temperature and temperature distribution in furnace and work is easier in a continuous than in a batch furnace. Examples for low and high temperature furnaces for small parts, strip and bright-annealing are described. Ha (5)

6

Determination of Temperature Distribution in Solid Bodies. W. TRINKS. *Ind. Heating,* Vol. 5, Oct. 1938, pp. 901-904. Discussion of a set of German graphs and tables on the cooling processes of simple hot bodies. The data simplify the finding of the temperature distribution in solids and the heating and cooling in steel and in furnace walls. Examples illustrate the practical application of some of the curves to problems in furnace design and application. Ha (5)

7

Practical Advantages in the Use of Special Refractories. H. E. WHITE. *Ind. Heating,* Vol. 5, Oct. 1938, pp. 945-952; Nov. 1938, pp. 1061-1063. Original research. Special refractories are termed those consisting essentially of the crystalline materials: Fused alumina, mullite and silicon carbide; the first and last are made in the electric furnace, while mullite is usually converted from kyanite, sillimanite and andalusite by heating at high temperatures for long periods. The melting points of some refractory materials are: Magnesia 2800° C., silicon carbide 2300° (dissociates), alumina 2050°, chromium oxide 1990°, mullite 1810°, silica 1713°; the specific gravity of fireclay (fired flint clay) is 2.55-2.75, crystalline alumina 3.91-4.01, mullite 3.03-3.10, silicon carbide 3.17-3.22. High grade refractories should contain at least 85% of either of the last 3 minerals. The various products on the market are discussed, and causes of failure by erosion and slag action described. Fused alumina refractories are preferably used where high temperatures and high bearing loads are combined (piers and supports). Mullite bricks have a high resistance to spalling and volume stability, and are used extensively in the glass industry, due to their low solubility in molten glass, and in metallurgical furnaces for their high strength and slag resistance. Bonded silicon carbide has proved extremely suitable for muffle furnaces for hardening high speed tools, mainly because of their high heat conductivity, thus giving a more uniform temperature. It is non-spalling and, therefore, used for hearth tiles and linings, to give longer life and greater economy. A curve is included to show the most economical time to replace the lining. Ha (5)

8

Characteristics of Fuel Oil and Their Effect on Furnace Design. D. A. WHITEHEAD (Shell Co. of Australia) *Heat Treating Forging,* Vol. 24, Aug. 1938, pp. 407-414. The characteristics of fuel oil are listed and its storage, handling, burning, vaporization, and atomization, characteristics of the flame produced and their application to metallurgical furnaces are discussed. Flame characteristics are: Liberation of a large quantity of heat in a small space, strong luminosity, large size and high temperature. These properties make oil fuel suitable for melting metals with high melting point in open-hearth, rotary and crucible furnaces. When melting metals of lower melting point in cast-Fe or cast-steel baths or pots, heat must be conveyed from flame to bath at a controlled rate and properly distributed. This can be done by propagating flame clear of bath itself and carrying hot gases around bath surface, or by having flame directly beneath bath, but interposing a thickness of refractory between bath and flame. Most applications of fuel oil in the metallurgical field, such as heat treating, require much lower temperatures than can be obtained in the oil flame. Heat transfer from flame to work must be adjusted so that the required temperature can be maintained in working chamber. There are a number of ways of doing this, some of which are discussed. These include situating flame some distance from work, and placing refractory between flame and work. For low temperatures, such as found in a mold stove, excellent results can be obtained with forced circulation. MS (5)

9

Practical Aspects of Controlled Atmosphere Annealing in Electric Tunnel Furnaces. J. MARLL. *Metal Treatment,* Vol. 4, Spring 1938, pp. 3-8. General discussion on choice and maintenance of controlled atmosphere furnaces. With a new furnace, tests should be made with a travelling thermocouple to determine the temperature gradient, the settings of the gas control valves determined, and routines established for securing the requisite dryness of the gas and freedom from S. Oil and grease must generally be removed from the work by pre-cleaning, preferably by trichlorethylene followed by a dip in boiling alkali. JCC (5)

10

The Processes in Electrode Saltbath Furnaces (Ueber die Vorgänge in Elektrodensalzbadöfen) K. A. LOHAUSEN. *Elektrowärme,* Vol. 8, Nov. 1938, pp. 283-288. Detailed description. The recent developments in 3-phase furnaces of the salt bath type, and the progress made by arranging the electrodes in such a manner that the useful bath space is kept large, uniform movement of the molten salt maintained, and uniform temperature distribution obtained, are discussed. These furnaces are used extensively for case-hardening as well as for simple heating in neutral salts. Ha (5)

"We have used Spencer Turbos in connection with our Coleman Core and Mold ovens for nearly 20 years. Their dependable operation under the severe conditions encountered in foundry service has been a source of satisfaction to our customers as well as to ourselves.

It has come to our notice that in a number of plants where we have furnished Spencer Turbos in connection with core oven equipment, our customers have been so well impressed with the operation that they have purchased Spencer Turbos for other pressure air requirements."

Innovations in Electric Furnaces (Neuerungen an elektrischen Öfen) *Tech. Blätter,* Vol. 28, Aug, 14, 1938, pp. 373-374. Description of a number of useful innovations in electric melting, annealing and heat treating furnaces, such as (1) a Siemens & Halske induction furnace with an arrangement of the annular hearth that makes possible tapping without current interruption, (2) Russ furnace with a special device for generating effective bath circulation, (3) AEG coreless induction furnace equipped with a non-magnetizable screen between induction coil and furnace shell to avoid its superheating, (4) coreless induction furnace by Hirsch Kupfer- u. Messingwerke, with an induction coil surrounded by a yoke effecting concentration of current flow upon the metal bath, (5) new type of continuous electric strip annealing furnace possessing separate heating elements that guarantees uniform heating throughout, (6) a Krupp continuous bright annealing furnace applying a controlled atmosphere, (7) a circular rotating hearth furnace for heating ingots and the like, and (8) a method to stop convection currents in electric bright annealing furnaces. Coiled Silicon Strip Steel. BURTON LONGWELL (Republic Steel Corp.) *Iron Age,* Vol. 142, Sept. 22, 1938, pp. 52-53, 82. Practical description of the advances made in the manufacture of coiled Si steel. Some of the developments are: A new annealing process so that the product would lay flat when uncoiled, and a method of restoring to the steel the desired electrical properties that were destroyed by cold strip rolling process. The Si steel is used in thickness of from 0.025 to 0.014 in. In cold working, which is necessary to get down to desired finish gage, the highly strained steel loses its electrical properties. Solution to above problems was the development of a new technique consisting of pulling ribbons of strip at a predetermined speed and temperature through atmosphere-controlled roller hearth furnaces. This gives the strip a uniform anneal and removes destructive effects on electrical properties. Another important feature of this annealing technique is that the oxide produced on Si strip is of a different nature from that produced on Si sheets. Considers the advantages of using coiled Si strip. VSP (5a)

The Quench-ageing of Steel. J. H. ANDREW & E. M. TRENT. *Iron Steel Inst.,* Advance Copy No. 1, Oct. 1938, 48 pp. Original research. Experiments were made to determine the effect of C upon the rate and magnitude of aging, as measured by increment in Vickers hardness. Aging was brought about by quenching the normalized steels from temperatures below the Ac_1 point. The effect of small additions of Si, Mn, Al and Mo were also determined. The method used was to carburize pure Fe in acetylene gas, along with pure Fe to which the special elements had been added. The carburized bars were sectioned by cutting them at such an angle as to allow a large number of hardness impressions to be taken between the carburized surface and the center of the bar. In nearly all cases the maximum increase in hardness at 25° C. occurred in a zone corresponding to a C content of approximately 0.035% after quenching from just below Ac_1. This C content corresponds to the amount regarded as the limit of solubility of C in α Fe. The addition of Mn up to about 1.0%, or the same amount of Mo, decreased the aging. Si up to 0.88% produced but small differences, while Al up to 0.47% brought about a decrease in hardening on aging. Nitrogenized Fe, after quenching from certain temperatures, gave a much greater increment in hardness than Fe-C alloys. Nitro-martensite, unlike martensite in Fe-C alloys, showed considerable aging at room temperature. The view is expressed that the increment in hardness produced by aging is due to the strain in the lattice produced by carbides of Fe or nitride of Fe, prior to their precipitation from solid solution. JLG (5a)

New Hardening Process for High Speed Steel. *Steel,* Vol. 103, Aug. 22, 1938, p. 46. Industrial note. New liquid carburizing method, called Valcase, has been developed by Chapman Valve Mfg. Co., Indian Orchard, Mass. Uses a fused salt-bath mixture [composition not stated] readily melted in ordinary pot furnaces without excessive fuming or smoking. Case depths range from 0.015 in. obtained in 30 min. to 0.045 in. obtained in 4 hr. Working range of bath is 1450-1700° F. Recommended operating temperature is 1650° F., although maximum case depths can be secured at 1700° F. One advantage claimed is that parts, when withdrawn from bath without quenching, may be readily machined, then reheated and quenched. Other advantages include uniform depth and hardness of case, rapid penetration, no corrosion of finished parts, fluidity of bath at operating temperature, high impact and wear resistance values, gradual merging of case with core, and no pitting or decarburization. "AMERICAN" ELECTRIC AIR TEMPERING FURNACES

FOR LABORATORY AND PRODUCTION

Model NA-21 Furnace
Container 16" Diam. x 20" Deep

Cylindrical Type NA

Specifically designed for fast uniform tempering of production or laboratory loads up to 1200°F.

The powerful directed air circulation insures dependable results at low cost.

Cleanliness and simplicity of operation reduce labor charges.

Ten standard sizes from 6" to 30" diameter and from 8" to 48" deep.

Ask for data to-day.

Effect of Cooling Velocity on the Transformations and Properties of Vanadium Steels (Einfluss der Abkühlungsgeschwindigkeit auf die Umwandlungen und die Eigenschaften der Vanadinstähle) F. WEVER & A. ROSE. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch, Düsseldorf,* Vol. 20, No. 16, 1938, pp. 213-227. Original research. Two V-steels with 0.5 and 1.0% V and 0.3-1.7% C, cooled at different cooling velocities, were thermally and micrographically examined. Undercooling diagrams are shown. Three undercooling stages can be distinguished: In the first stage, for cooling velocities up to about 20°/sec., the pearlite transformation is reduced to about 600° C., precipitation of V-carbide is suppressed, and ferrite and cementite precipitation is unchanged. The structure shows transitions from ferrite-pearlite mixtures to "sorbite" in the hypoeutectoid steels, from coarse spheroidal cementite to "sorbite" in eutectoid steels, and "sorbite" and cementite needles in hyper-eutectoid steels. Hardness increases rapidly with cooling velocity. The second stage starts from about 15° C./sec.; the eutectoid ferrite precipitation is suppressed, the temperature of the austenite precipitation drops from about 525° C. at low C contents to about 450° at 1.5% C, and is independent of cooling velocity. This stage is always connected with recalescence and characterized by needle-like structures similar to martensite but quite distinct from the pearlite of the first stage. The hardness decreases in the hypoeutectoid and eutectoid steels, and increases in the hypereutectoid steels with increasing cooling velocities. Stage 3 is the martensite stage and covers the total transformation process. The temperature of the martensite transformation is the same as in C steels and independent of cooling velocities. The structures of the martensite stage do not differ essentially from those of unalloyed steels; the martensite is usually very fine. The hardnesses increase in this stage with increasing cooling velocities to a maximum of about 900-950 Vickers units. A decrease occurs again at very high velocities because of the increasing amount of untransformed austenite. The behavior of V steels at higher cooling velocities lies between the C steels and the high-alloy Cr-Ni steels. 12 references. Ha (5a)

Heat Treatment by High Frequency Induction. L. C. CONRADI (Internatl. Business Machines Corp.) *Metal Progress,* Vol. 34, Sept. 1938, pp. 214-217. Discussion of the benefits derived as to the saving in time in the heat treatment of small parts by the induction method. The quenched spark gap high frequency unit is used on a 60 cycle 220 volt line, and produces sufficient power at the working coil end to quickly heat small machine parts to temperatures above their critical for annealing and hardening operations. Case carburized parts can be hardened by this method. Induction heating offers the additional advantage that it is possible to use a 0.40-0.50% C steel and alloy steels for many gears and cams instead of a low C carburizing grade, and thus eliminate the costly selective case hardening operation. In all instances, induction heating produces a minimum amount of scale on the parts treated. Selective hardening is possible, owing to the fact that the primary or working coil can be so placed as to heat the particular spot to be hardened. [The last sentence can be explained further by saying that the metal part to be hardened, when placed within the working coil, virtually short circuits the induced current within the coil and causes a sufficient number of eddy currents to be set up within the metal in this area to raise its temperature to above its critical point. Therefore, only the metal within the coil becomes heated to the high temperature, the adjacent metal being heated by conduction only. A thermocouple could not be used in this case, owing to the electrical field set up, but the experienced operator could judge the temperature of the metal part by eye.—C. W. H.] CWH (5a)

The Influence of Low Temperatures on Quenched EI173 and EI184 Steels. N. MINKEVICH, O. IVANOV & YA. DOVGALEVSKII. *Stal,* Vol. 8, Apr. 1938, pp. 63-65. In Russian. Original research. EI173 (1.10% C, 0.25% Si, 0.4% Mn, 2.38% W, 0.81% V, 9.20% Cr) and EI184 (0.98% C, 0.62% Si, 0.4% Mn, 4.08% W, 1.56% V, 8.68% Cr) steels contained 50-60% retained austenite after oil quenching from 1200° C. Cooling below 0° C. transformed this austenite into martensite, the transformation being almost complete in 3 min. at —70° C. The austenite remaining at —70° C. was high in alloy content, and further cooling to —183° C. would not transform it. The specimens after cooling were subject to aging at 100° C., which increased their hardness about 2 units Rockwell C. HWR (5a)

Stress Relieving and Preheating. W. G. THEISINGER (Lukens Steel Co.) *Iron Age,* Vol. 142, Oct. 13, 1938, pp. 131-132, 134, 136, 138; Oct. 20, 1938, pp. 22-25. Practical discussion. Points out some of the problems of present day welding, describes welded specimens prepared to study the effect of stress relieving, and lists the experimental data obtained. Considers also the effect of stress relieving on hardness and microstructure, and residual stresses in welding heavy plate sections. Includes a number of graphs and photomicrographs. Steels used were S.A.E. 1035 and 150. VSP (5a)

Small, intricate machined parts are no longer a problem to heat treat when using this Reciprocating Full Muffle Machine.

Decarburization, distortion (warping) and scaling are eliminated due to atmosphere control and uniform heating.

These machines are serving many on difficult problems of this nature. Can they be of service to you?

Write for bulletin MA239.

LONG VITREOSIL TUBES

for

METALLURGICAL USE

We are in a position to quote attractive prices on Vitreosil (vitreous silica) tubes 10 feet in length or even longer, in one piece. Like all Vitreosil products, these are immune to attack by acidic materials and intense heating or sudden changes of temperature.

On account of its chemical purity and complete freedom from carbon, iron, etc., Vitreosil offers unique advantages in metallurgical fields. Such tubes are especially suitable for reduction and chloridizing processes, construction of continuous rotary furnaces, etc., and may be directly wound with resistance wire for electrical heating.

We shall be glad to receive your inquiries for tubes in special lengths.

The Thermal Syndicate Ltd.

12 East 46th Street

New York, N. Y.

RYERSON CERTIFIED STEELS

Special Alloy Steel Plan Aids Steel Treater

Ryerson Certified Alloy Steels are from selected heats that meet an ideal specification — a "specification within a specification" that assures year after year uniformity. Ryerson Certified Alloys are analyzed and tested in advance. Special data sheets are prepared and sent with every shipment. With these data sheets, the heat treater does not have to test. He gets better results in less time. Let us tell you the complete story. Write for Booklet. Joseph T. Ryerson & Son, Inc. Chicago, Milwaukee, St. Louis, Cincinnati, Detroit, Cleveland, Buffalo, Boston, Philadelphia, Jersey City.

Oxyacetylene Surface Hardening. A. K. SEEMANN. *Mech. Eng.,* Vol. 60, July 1938, pp. 535-540. A flame-hardening process may be applied to any ferrous material that will respond to simple heating and quenching to develop hardness. The procedure is described in detail, and the advantages summarized as: Equipment is in instant readiness; simple straight C steels or low alloy steels can be used; operation is rapid; only the surface is hardened at exactly the desired place; depth can be varied; the size of the piece is immaterial; there is little tendency to distortion; and the portable equipment can also be used for flame softening. Ha (5a)

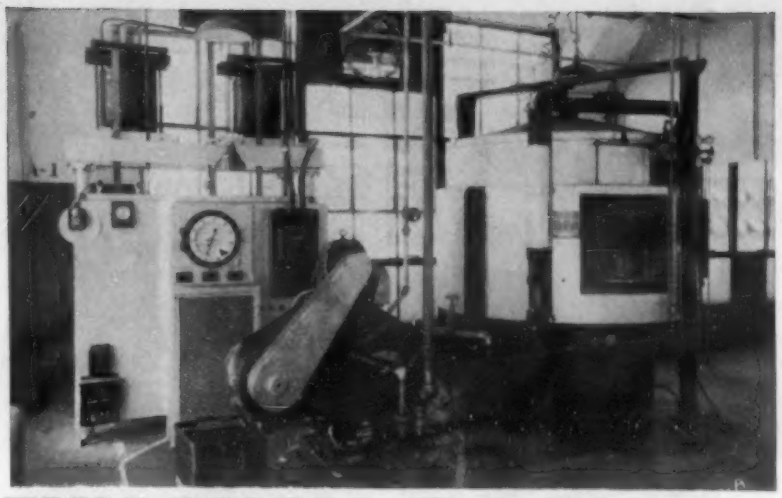
JZB (5a)

Lightweight Refractories. L. W. BERTELSEN (Armstrong Cork Prod. Co.) *Steel,* Vol. 103, Oct. 3, 1938, pp. 44, 46. Descriptive. Car-type furnace for heat treating rolling-mill rolls is 35 x 10 x 12 ft. high. Side walls consist of an average of 11 in. of insulating fire-brick, backed with an average of 7 in. of another type of insulating fire-brick, inclosed in a steel shell. An arch of similar construction uses 9 in. and 4½ in. of the respective types of brick. The furnace has been fired to 2150° F. maximum and is held under positive pressure with neutral or slightly oxidizing atmosphere. Reducing atmosphere is sometimes used. In the usual cycle, the furnace is brought to 2000° F. about every 3 weeks and held for 2½-3 days. The temperature is then reduced to 1500° F. within 6 hrs. The charge is withdrawn and temperature is dropped to 1000° F. within 15 min. The inner surface was given a glazed finish by applying a clay that glazes at about 2200° F. This increases the furnace efficiency, owing to the radiation from interior walls and by sealing the furnace to prevent heat losses from air infiltration. Tests have shown that the temperature of the walls is lower than that of the charge. Fuel saving, compared with furnaces formerly used, is more than 45%. Temperature difference in any part of the furnace is less than 10° F., assuring uniform heating of entire length of rolls, some of which weigh as much as 100,000 lbs. During the flood, the furnace was submerged to a depth of 11 ft., but the walls were found to be intact in every respect after the waters receded. After 4 years' continuous operation, the furnace is fit for many years' more service. MS (5a)

Surface Hardening of Steel by Heating with High-frequency Current (La Trempe Superficielle de l'Acier par Chauffage au Moyen de Courants à Haute Fréquence) G. BABAT & M. LOSINSKY. *Rev. gén. élec.,* Vol. 44, Oct. 22, 1938, pp. 495-510. Review. The skin effect exerted by high frequency current in solid metals is utilized to heat steel (shafts, cylinders, large, solid pieces in general) by placing them in a magnetic field of high frequency formed by inductively arranged water-cooled coils. The general laws of induction heating and the current distribution in the interior of the steel are explained and the energy expanded by the Foucault current calculated; the optimum conditions for heating are determined for different shapes, and an installation using a vacuum tube generator is described. Ha (5a)

Diffusion Annealing of Flake-sensitive Steel. E. A. KLAUSTING. *Metallurg,* Vol. 13, Mar. 1938, pp. 55-61. In Russian. Original research. Diffusion annealing for 20 hrs. at 800° C. (directly after forging) was found sufficient for complete elimination of flake-sensitivity in square samples of 100 mm. on a side. An increase in the temperature up to 1050° C. speeds up the process, but any further increase gives no substantial acceleration. Extended annealing at 1160°-1180° C. reduces the flake-sensitivity, but complete elimination requires a long time. The disappearance of flake-sensitivity during annealing is not due to the homogenization of H_2 in the solid solution but to its evolution from the steel. Optimum conditions for diffusion treatment are in many cases not yet definite. BZK (5a)



Hardening "Moly" Steels. *Steel,* Vol. 103, Oct. 3, 1938, pp. 48-49. Descriptive. Mo steels with 0.40-0.50% C are particularly adapted to flame hardening, as close temperature control is not imperative in this case and, next to C, Mo is the most effective hardening agent normally added to steel. Regardless of the type of steel, C range should be 0.35-0.50%, preferably 0.40-0.45%. Steels should be fine grained. Physical properties desired in the core of the finished part determine preliminary heat treatment. It is recommended, however, that steel be at least normalized. Flame hardening has no effect on core properties developed by preliminary heat treatment, and produces no distortion in Mo steel parts after hardening. Cr-Mo steels, SAE 4140 and 4150 are prominent among those suitable for flame hardening. These harden in excess of 80 scleroscope or 600 Brinell, for case depths up to 5/16 in. Hardened parts show uniform case depth. Hardness decreases gradually, instead of abruptly. Between case and core, there is a zone where structure changes gradually. This acts as a bond and tends to reduce spalling of case under load. Mn-Mo steel containing 0.40-0.45% C, 1-1.20% Mn and 0.20-0.30% Mo gives excellent results. Steel with 0.45-0.55% C, 1-1.25% Mn, 0.40-0.60% Cr, 0.06-0.10% S and 0.10-0.20% Mo has been flame hardened. Pins made of 0.50% C steel of this type, heat treated to 150,000-170,000 lbs./in.^{2} tensile strength, were hardened to produce a 1/16 in. case with hardness of 700 Brinell. MS (5a)

Temper-brittleness in Alloy Steels. J. A. JONES. *Metal Treatment,* Vol. 4, Autumn 1938, pp. 97-101. Original research. Steels that show no signs of temper-brittleness after slow cooling at the rates usually employed (⅓° C./min.) may still exhibit brittleness on prolonged service at 350°-500° C. Determinations of the notched bar impact strength of 8 steels after heating for periods up to 3000 hrs. at 350°, 400° and 450° C. indicate that appreciable embrittlement occurs in 3% Ni-Cr, 3½% Ni and 3% Ni steels, particularly at the higher temperatures. The addition of 0.32% Mo to a Mn-Mo steel with 1.55% Mn heat-treated to 62 tons/in.^{2} is not sufficient to stop long-time embrittlement, but a steel with 0.21% Mo and 1.42% Mn heat-treated to 47 tons/in.^{2} shows much less embrittlement. A new steel (Durehete) containing 1% Cr, 0.57% Mo, 0.65% Mn and 0.5% C is not affected after 20,000 hrs. at 415° C. The observations of Houdremont & Schrader (*Metals and Alloys,* Vol. 5, Apr. 1934, p. MA 133) that repeated slow coolings from 650° C. will restore the impact values have been confirmed. This improvement, however, is accompanied by a drop in hardness. By repeated slow coolings from 600° C., a similar recovery in impact strength can be secured, with less softening. JCC (5a)

Spring Washers. *Steel,* Vol. 103, Oct. 17, 1938, pp. 58-59. Describes heat-treating practice of Philadelphia Steel & Wire Corp., Philadelphia, Pa. Fine-grained spring steel, with 0.60-0.70% C, in hot-rolled rounds and shapes is used. It is cold drawn to the various sizes required. Some of the smaller sections require 8-10 passes through wire-drawing plates. Wire is given a spheroidizing treatment at about 1300° F. between each pass. Washers are fabricated on specially designed machines that coil and automatically sever each convolution. Hardening is done in automatically controlled closely muffled rotary-retort type gas-fired furnaces. At the discharge end, work passes through an oil-sealed chute into a rotary quench drum without coming into contact with atmosphere, thus holding decarburization and scaling to a minimum. After fracture and hardness tests are made, washers are washed to remove quenching oil, and drawn at 500°-700° F. in an automatically controlled electric dense-load forced-convection air-tempering furnace. Hardness of 48-53 Rockwell C is produced. MS (5a)

Precipitation-hardening in Three Steels Containing Vanadium. H. H. BURTON & T. F. RUSSELL (English Steel Corp.) *Iron Steel Inst.,* Advance Copy No. 4, Oct. 1938, 18 pp. Original research. One steel contained 0.26% C, 0.58% Mo and 0.30% V; another, 0.20% C, 0.60% Mo and 0.30% V; while the third contained 0.25% C, 0.66% Cr, 0.56% Mo and 0.30% V. All were susceptible to temper-hardening processes when tempered in the range 500-625° C. The degree of hardening depended on both the time and temperature of tempering. Temper hardening was accompanied by a marked drop in notched-bar impact resistance, but toughness was recovered when softening set in, due to coalescence. From a detailed study of the tensile strengths, impact values, dilation, relative densities and carbide analyses on one steel, it was concluded that the temper hardening was due to precipitation of V_4C_3 from supersaturated solution in α Fe, as suggested by Houdremont, Bennek and Schrader. Precipitation of Fe_3C may be somewhat of a factor in the hardening. JLG (5a)

Practical Pointers on the Heat Treatment of Tools. R. B. SEGER (Lindberg Steel Treating Co.) *Modern Mach. Shop,* Vol. 11, Oct. 1938, pp. 54-60. Practical suggestions are given on proper treatment of tools, according to their composition to avoid warpage and size change. Slow and uniform heating, uniform quenching, quenching solutions and air quenching are discussed, and surface changes explained. Ha (5a)

THIS SMALL FURNACE

HARDENS 250 LBS. PER HOUR—*SCALE FREE*

While The Electric Furnace Co. is widely known as builders of large production furnaces, we also build numerous smaller continuous automatic units.

The above rotary, scale-free hardening furnace is an excellent example. This comparatively small and inexpensive installation handles miscellaneous small and medium sized products such as springs, bolts, screws, etc., at the rate of 250 lbs. per hour.

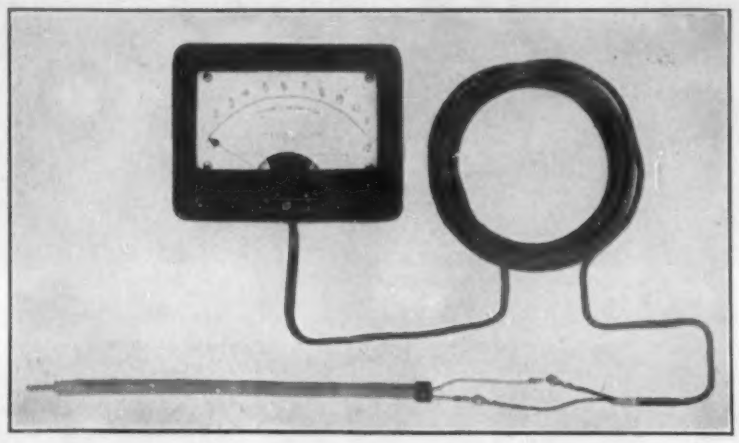
The complete unit consists of furnace, quenching equipment, automatic control and an Elfurno generator for supplying the protective atmosphere for scale-free hardening.

This furnace has two doors and two quench tanks—the hearth operates in either direction enabling material to be either oil or water quenched without moving quench tanks or changing quenching medium.

Submit your furnace problems to E. F. engineers. With years of experience, and hundreds of successful electric and fuel-fired furnace installations, we have solved many difficult production furnace problems—experience which may save you considerable on your particular furnace problem.

The Electric Furnace Co., Salem, Ohio

Gas Fired, Oil Fired and Electric Furnaces—For Any Process, Product or Production



For that better Electric Furnace or Electric Appliance, use "Tophet" nickel chrome wire, long-lived, dependable and always uniform.

WILBUR B. DRIVER CO.

NEWARK, NEW JERSEY

Complete Industrial Pyrometer Installation only $60.00

Vibration Proof — Critically Damped
Powerful Cobalt Magnet - Aircraft Precision

This complete pyrometer installation includes a pyrometer with a six-inch scale, lead wire, thermocouple, and protecting tube. Approved by Army and Navy for aircraft, this pyrometer offers guaranteed accuracy and ruggedness for industrial pyrometer service.

The Heat Treatment of Steels in Neutral Atmospheres (Sur les Traitements Thermiques des Aciers en Atmosphères Neutres) E. HERZOG. *Métaux & Corrosion,* Vol. 13, Sept. 1938, pp. 153-163. Review. The Fe-O_2 reaction is discussed. The O content in a reducing atmosphere (CO, H_2) should not be more than 0.4%. About 0.2% Ni or Cu somewhat reduces the oxidation of the steel. Review of the Fe-H_2/H_2O and Fe-CO/CO_2 reactions shows that the oxidation of Fe is prevented when the H_2/H_2O ratio is 0.8/0.20 between 600° and 1100° C., or when the CO/CO_2 ratio is 0.75/0.25 between 500° and 1100° C. Sulphur dioxide is also an important factor in steel-gas reactions. In presence of Ni in steel, the SO_2 from the fuel causes a deterioration along the grain boundaries with the formation of S and Ni oxide. Protective atmospheres in current use are discussed; these are N_2, H_2, H_2-N_2 mixture, H_2-CO mixture, hydrocarbons, etc. 22 references. GTM (5a)

Tempering Martensite (Studio sul rinvenimento della martensite) V. MONTORO & V. ROSSI. *Met. Ital.,* Vol. 30, Sept. 1938, pp. 495-498. Original research. Systematic determinations of the temperature coefficient of electrical resistance in relation to the hardening and tempering of a "eutectoid" steel (0.75% C, 0.24% Mn, 0.18% Si, 0.014% S and 0.011% P) were made. The resistance was determined at 20° C. and at 40° C., and the coefficient of resistivity α calculated using the formula $\alpha = \frac{1}{\rho_{20}} \frac{\Delta\rho}{\Delta t}$. The steel was first hardened from 790° C., then tempered at increasing temperatures. Below are listed values for $\alpha \times 10^4$:

Tempered at °C.	$\alpha \times 10^4$
40	18.2
100	18.3
150	21.0
200	25.5
300	27.5
400	29.8
680	31.2

Thus, the value of α is an index of the temperature at which the steel was tempered. AWC (5a)

Quantity Production. WALTER G. BAIN (Allis-Chalmers Mfg. Co.) *Steel,* Vol. 103, Sept. 5, 1938, pp. 56, 58. Describes automatically controlled and conveyorized carburizing, hardening and drawing furnaces of continuous type installed in tractor works of the author's firm at Springfield, Ill. These have increased the amount of work handled and lowered costs per unit. Old pack hardening equipment has been replaced by continuous gas carburizing units (overall length, 55 ft. each) that operate on a 15-hr. cycle and produce 450 net lbs. work/hr. of carburized track pins, bushings and shafts of S.A.E. X-1020 steel. Carburized parts are hardened in continuous belt-type furnaces. Track links of S.A.E. 1045 steel are hardened differentially by heating in rotary hearth furnaces, discharging manually and placing in timed quenching jigs. Track shoes and axle shafts are hardened in large 3-zone furnaces with continuous chain-belt hearths, time-quenched in water and tempered at 300°-500° F. in recirculating hot air furnaces. Forged drive sprockets are quenched in a new centrifugal quenching machine, which hot-forms the piece and automatically times the quench to harden only the teeth. MS (5a)

Grain Size and Hardenability in Steels to Be Heat-treated. EDGAR C. BAIN (U. S. Steel Corp.) *Iron Steel Inst.,* Advance Copy No. 2, Oct. 1938, 24 pp. Up-to-date review. Numerical data show quantitatively the degree to which increasing grain size in a hardenable steel of given composition increases the hardenability and, similarly, indicates the degree of the superiority with respect to toughness or impact strength of the heat-treated steel of fine austenitic grain size. An explanation of grain-size effects is offered and supported, which postulates that the hardenability is a matter of the rate of nucleation and that the grain size is both one of the means of controlling nucleus formation and, at times a reflection of it. JLG (5a)

Carburization of Steel by a Gaseous Carburizer (Das Aufkohlen von Stahl durch ein gasförmiges Kohlungsmittel) *Tech. Blätter,* Vol. 28, Sept. 18, 1938, pp. 560-561. Descriptive. A new gas carburizing method employs 3 different stages of treatment. Within the first temperature range, 650°-815° C., the hydrocarbon carburizing medium is decomposed, partly catalytically by the work. In the second temperature range, 840°-980° C. the carbon deposited is oxidized to CO, which is the actual carburizing medium. Finally, a subsequent diffusion takes place at the same temperature. The carburizing gas is composed of a hydrocarbon, an oxidizing medium, essentially CO_2, and a diluting agent, *e.g.* dried flue gas with 8-15% CO_2. GN (5a)

Heat Treatment for Die Blocks. T. A. LEDIN (A. Finkl & Sons Co.) *Iron Age,* Vol. 142, Aug. 25, 1938, pp. 41-43. Practical description of furnaces for heating die blocks. They are of semi-muffle, gas-fired box type, controlled automatically. After heat treatment, blocks are water-quenched and tempered. Furnaces are vertical pit type having separate combustion chamber behind heating chamber. Temperature may be controlled within 5° F. VSP (5a)

Flame Hardening and its Principles. H. H. LANGEBECK. *Welding J., N. Y.*, Vol. 17, Sept. 1938, pp. 28-32. Research reported for effect of Mn on hardness obtained in flame hardening, using low and high pressure air and water for quenching. With a Mn spread from 2.2 to 2.9% (C, 0.22 to 0.33%) hardness rises from 380 to 580 Brinell for water quench. Surface cracking does not occur with Mn up to 2.9% if the steel has been properly annealed before hardening and if the hardening operation is well controlled. Two methods of flame hardening, (1) progressive and (2) spinning are discussed as to hardening conditions, hardness penetration and transition zone. In (1), where the quench follows the torch, the flame size, distance from treated surface and speed of travel control hardness and penetration. In (2), where the steel is spun, heated with the torch and quenched by immersion, the above factors apply, together with the number of revolutions during treatment. The latter discussion is in the nature of a review of the literature with curves to show relationship between temperature attained, hardness and penetration. The softer transition zone below the hardened zone is considered of benefit in preventing spalling of hardened surface, due to its ductility.
WB (5a)

Some Factors Influencing the Durability of Chrome-magnesite Bricks in Basic Open-hearth Steel Making Furnaces. W. HUGILL & A. T. GREEN. *Trans. Ceram. Soc.*, Vol. 37, July 1938, pp. 279-288. Original research. The deterioration and crumbling of chrome-magnesite bricks taken from a basic open-hearth furnace that had been subjected to very severe conditions after 190 heats are assumed to be due to the following mechanism: (1) Fe oxide is absorbed by the hot face of the bricks. In this zone the grains of chromite grow by taking magnetite into solid solution. The matrix, which is relatively rich in magnesia, is largely converted into a less refractory mixture of magnesia, ferrite and meta-silicates. (2) The strains set up by the growth of the chromite grains induce: (a) A crumbling disintegration of the working face; (b) a movement of the mobile matrix within the brick until it reaches a zone where the temperature is such that it can solidify; (c) the formation of a layer about ½-1 in. thick by this process. (3) When the hot face has been worn back further by disintegration, the temperature rises at the second zone, liquefaction again takes place, with the result that a more serious breakdown of the surface occurs. GTM (5a)

Lathe Beds Are Flame Hardened in One Pass. *Steel*, Vol. 103, Oct. 10, 1938, p. 96. Descriptive. Beds are alloy steel castings having a hardness of 225-240 Brinell. After finish-planing, ways are clamped in a water tank with just the surface extending out of the water. Oxyacetylene torches with multiple tips fastened in a carriage traverse length of ways at 3-6 in./min., depending upon thickness of the bed section being hardened. Tips are the quenching type. Depth of penetration of hardened metal varies from ⅛ to ¼ in. or more. Strains are prevented by keeping bed at room temperature during hardening. Repeated tests show no tendency for hardened portions to crack or flake, even under abuse. Hardened way surfaces have a hardness of about 590 Brinell. Distortion varies from 0.005-0.015 in. over length of entire bed and is corrected in subsequent grinding. Exact procedure details are determined by tests on way sections about 13 in. long.

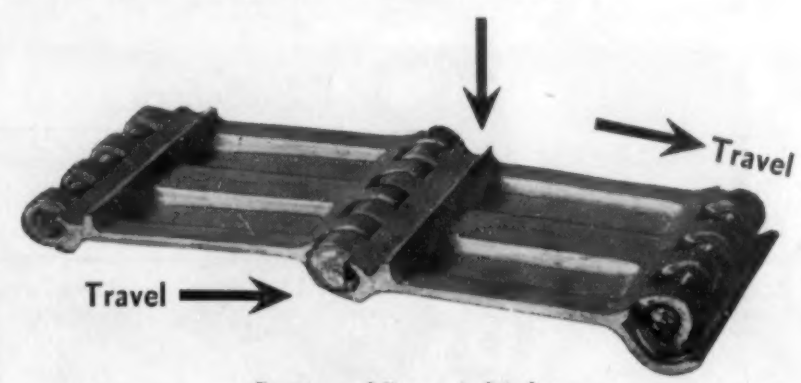
Bright Annealing Wire. J. B. NEALEY. *Steel*, Vol. 103, Oct. 31, 1938, pp. 50-51. Describes practice of F. A. Harris, Inc., Springfield, Mass., in manufacturing fine wires of brass, bronze, Ni, Ag, Monel and other non-ferrous metals and alloys. Wire is drawn down from ⅛-in. round stock in continuous machines containing 10-22 drafts or dies each. Tungsten carbide dies are used in reducing large wire, and diamond dies small wire. Each reduction is usually followed by an anneal. Frequency of anneal varies with type of wire. Strands are annealed individually in a continuous furnace, 18 ft. long with heating chamber 25 in. wide and 14 in. high, holding up to 120 lengths of ordinary Fe pipe, through each of which a single strand passes. Pipes containing prepared atmosphere, introduced through manifolds of block castings about 3 ft. from discharge end of tubes, to assure bright finish. Various atmospheres, such as CO_2, N_2, H_2 and city gas, are used, depending upon product. Furnace temperatures range from 700°-1650° F., while wires are pulled through at 50-600 ft. per min. There are 26 gas burners on each side of the underfiring hearth, and 3 separately controllable temperature zones. MS (5b)



CALITE

CHROMIUM NICKEL-MOLY ALLOY CASTINGS

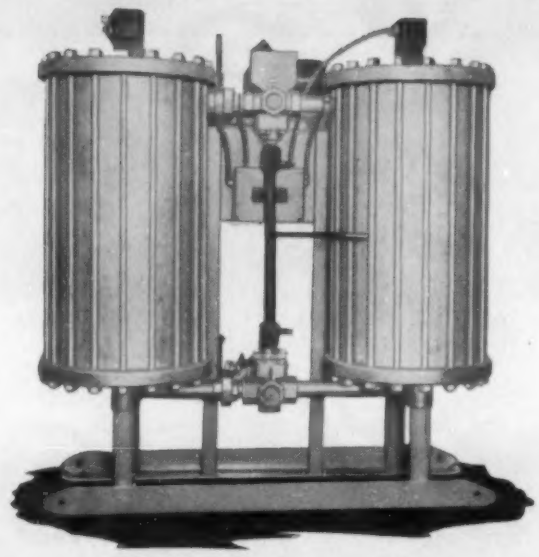
For heat treating small parts, or parts with sharp edges or fins—investigate the BROWN CHAIN-BELT with SHROUDED HINGE

Top View—4 links—1/64th side clearance. Note shroud covers "piano hinge." Driving tooth here

Bottom View 4 Links

RELIABILITY—from straight across driving tooth. No stoppages from teeth failing to mesh in pockets and "riding up." No jamming of hinges with sharp edges of stock.

LONGER LIFE—great bearing area of "piano hinges." Highest creep strength Cr-Ni-Moly Alloy. Most of metal in straight tension.



GREATER STRENGTH—Due to: Deck on hinge line—no bending except during tooth load. Driving teeth full width. Rectangular corrugations. Permits higher loadings or higher temperatures (2000F), and longer lengths.

Some Characteristics of Copper-aluminum Alloys Made from Aluminum of Very High Purity. MARIE L. V. GAYLER. *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 807, 15 pp. Original research. It is very difficult to obtain a 4% Cu-Al alloy made from super-pure French Al in such a condition that it will age harden uniformly to the maximum extent at room temperature. Hot working followed by solution heat treatment at 500° C. results in little or no hardening at room temperature. The microscopic examination of such material shows segregated areas of fine particles of $CuAl_2$, which alone would be sufficient to account for non-uniform results. The lack of homogeneity in the age hardening is due to the fact that the alloy is not easily work hardened, owing to the Al matrix being plastically deformed without appreciable work hardening, probably because of self-annealing during working, and also because particles of $CuAl_2$ act in a manner similar to that of the hard particles in a bearing alloy and are, therefore, little deformed except under special conditions. A brief examination was made of the effect of added impurities on the grain growth of recrystallized Al. The fine grain size of the 4% Cu alloy containing Fe is due to the mechanical prevention of grain growth by the presence of the insoluble Fe-rich constituent in the grain boundaries. JLG (5b)

Development of Abnormally Large Grain Sizes in Rolled and Annealed Copper Sheet. MAURICE COOK & C. MACQUARIE. *Metals Tech.,* Vol. 5, Sept. 1938, T.P. 974, 16 pp. Original research. Abnormally large crystal sizes can be developed in rolled Cu strip or sheet provided the final cold rolling reduction exceeds about 95% and the final annealing temperature is of the order of 1000° C. Also, large crystals can be produced under the same conditions of final annealing, with a cold reduction of not less than 85%, provided the temperature of the penultimate anneal does not exceed 550° C., and that the total cold rolling exceeds 96%. The structure after these heavy reductions is similar whether the final rolling is the same or normal to the direction of previous rolling. If the final reduction is limited to 30-70%, and is effected normal to the direction of previous rolling, the largest crystal size is obtained by annealing finally at about 800-850° C. The crystals in this case are smaller, more equiaxed, and free from circular markings and structures. These results were obtained with 2 brands of high-conductivity Cu, but with P-deoxidized Cu and less pure Cu, such as tough pitch and As-Cu, large crystals were not produced by any sequence of operation. JLG (5b)

Some Furnaces for Aluminum Alloys. *Aluminum & Non-Ferrous Rev.,* Vol. 3, Aug. 1938, pp. 304-307. Descriptive. Electric furnaces are described for melting, billet heating and heat treating of Al alloys. For melting, a pot type furnace with hairpin heating elements is recommended. For billet heating, either batch-type or continuous furnaces can be used, depending on work; they are equipped with forced air circulation. Charging and moving can be done by means of: Inclined hearth, roller hearth, conveyor or slide rails. Heat treatment of Al alloys is done mostly at temperatures around 500° C. for solution treatment and 150°-200° C. for age hardening, respectively. The use of salt bath is not recommended because of difficult handling, cost of bath and trouble in getting the pieces to the quenching container without appreciable loss of heat. Electric furnaces with forced air circulation are preferred. They are available as horizontal and vertical types. RPS (5b)

Salt Baths for Heat Treatment of Light Alloys. *Aluminum & Non-Ferrous Rev.,* Vol. 3, Sept. 1938, pp. 332-334. Descriptive. Until recently salt bath furnaces had the disadvantage of high maintenance cost, chiefly because of deterioration of the tank or pot containing the liquid salt. A temperature gradient of 200° C. through the sides of the pot was not unusual, setting up severe stresses on the pot material. Another disadvantage was the danger of explosion offered by the muddy sediment of aluminum oxide that forms in the bath and settles to the bottom. These disadvantages are overcome by the use of special immersion heaters mounted a few inches above the bottom of the bath. The heating elements can be replaced without disturbing the bath. A number of safety devices are used to protect the furnace against excess temperature, drop in temperature, salt leakage, etc. RPS (5b)

An X-ray Investigation of Al-Cu Alloy and Duralumin Aged at Room and Higher Temperatures. T. TAKEUTI. *Nippon Kinzoku Gakkai-Si,* Vol. 2, Oct. 1938, pp. 514-518. In Japanese. Original research. By means of X-ray diffraction, hardness test and microscopic examination, the change in structure of quenched Al-Cu alloy (3.4% Cu) and duralumin during aging and tempering at room temperature and at temperatures ranging from 150° to 350° C., is studied. In the aging temperatures between 150° and 200° C., complete agreement is obtained between the maximum width of diffraction and maximum hardness, but there is no broadening of diffraction—inspite of marked variation in hardness immediately after quenching, after aging at room temperature and after heating for 1 hr. at 150° C. NS (5b)

Aging. MARIE L. V. GAYLER. *Metallurgist (Suppl. Engineer)* Oct. 1938, pp. 166-169. Part I of a very comprehensive review. Aging is considered under the following headings, the first 2 of which are covered in this issue: (1) Equilibrium diagrams of alloys that possess the property of age hardening; (2) characteristics associated with age hardening; (3) factors affecting age hardening; (4) theories of age hardening; (5) practical applications of this property in alloys; and (6) associated problems of age hardening that need further investigation. 36 references. VVK (5b)

Age-hardening of Duralumin. MORRIS COHEN (Mass. Inst. Tech.) *Metals Tech.*, Vol. 5, Oct. 1938, T.P. No. 978, 12 pp. Original research. Aging in quenched duralumin was followed at 30, 65, 100, 150 and 191° C. by hardness, microscopic, lattice, length and electric resistance changes. Results indicated that the basic aging mechanism involves a pre-precipitation stage as well as actual precipitation. The pre-precipitation change is a process of nucleus formation in preparation for the precipitation of $CuAl_2$. Localized precipitation sets in first along the grain boundaries, and this is followed by general precipitation within the grains. The pre-precipitation stage is indicated by a slight contraction and a considerable increase in electric resistance, but no change in microstructure or lattice parameter. The localized precipitation stage is characterized by a slight expansion, a modest decrease in electric resistance and a darkening of the grain boundaries, but still no change in lattice parameter. The general precipitation stage is accompanied by a large expansion, a rapid decrease in resistance, a darkening of the whole microstructure and a change in lattice parameter. These 3 stages may overlap to a considerable degree; but they proceed at different rates and are sufficiently distinct in duralumin to result in 3-step hardening. During the room-temperature aging of duralumin, the hardening is essentially due to nucleus formation. Any actual precipitation that may occur at room temperature is incidental and not a vital factor in the hardening mechanism. This combination of nucleus formation, localized precipitation and general precipitation offers a comprehensive picture of the age-hardening process. JLG (5b)

X-ray Studies of the Age Hardening of Super-duralumin. G. SHINODA. *Nippon Kinzoku Gakkai-Si*, Vol. 2, Sept. 1938, pp. 475-481. In Japanese. Original research. The aging of super-duralumin (RF 1:4.01 Cu, 1.77% Mg; RF 2:4.09 Cu, 1.12% Mg) and Al-Cu alloys (2% and 4% Cu) was investigated by the X-ray back reflection focussing method using Cu K_α radiation. The quenched specimen was fixed on an X-ray camera and the incident X-ray beam was adjusted so as to illuminate the same part of the specimen always from the same direction. Photographs were taken immediately after quenching, after 15 min., 30 min., 1 hr., etc. Some of the spots reflected from (511) planes of super-duralumin change their shapes by internal strain or by bending of crystal grains during aging; this continues for several hours. At first, the change in the position of the spot is random but finally it displaces to the side of larger lattice constant. The mean dilatation of the lattice after 20 hrs. was 0.0121% and 0.0274% for RF 1 and RF 2, respectively, while the lattice constants immediately after quenching were 4.036 and 4.035 A.U., respectively. The change in the shape of the spot and the displacement of its position is not remarkable in Al-Cu alloy, but in 4% Cu alloy, bending of the atomic plane during aging was very noticeable. The tendency of lattice dilatation in Al-Cu alloys was also observed. NS (5b)

NOW! DuPont offers..

Du Pont's Complete Line of Heat-Treating Salts Includes:

No. 1—for tempering and drawing steel between 300° and 1100° F., heat coloring.

No. 2—tempering and drawing steel between 450° and 1200° F., heat coloring.

No. 3—general use between 1150° and 1700° F., bath heating medium for austempering; hardening and annealing steel; annealing non-ferrous metals; salt core for lead baths.

3A, 4A and 6A—special modifications, designed for ferrous metal treatment. Contain borax rectifier to flux out oxygen carriers and prevent excessive decarburization.

No. 4—annealing and hardening tool steel, alloy steel, 1300°-1700° F., least dense and lowest priced salt in series.

No. 6—very dense salt with wide operating range, 1050°-1850° F. Less volatile than No. 3 or 4, it is recommended for continuous operation above 1600° F.

Also, CYANEGG (96% Cyanide, min.); Cyanide Chloride, 75% and 45%; du Pont Case Hardener (30% Sodium Cyanide; du Pont Accelerated Salt and Carburizing Salt.

A COMPLETE LINE OF EFFICIENT, ECONOMICAL HEAT TREATING SALTS

The experience of many years has gone into the preparation of this complete line of salts for molten baths. Wide operation range . . . low cost . . . economy in use make them particularly satisfactory for general use and special work. High temperature salts contain a rectifier flux to check decarburization of ferrous alloys. If you haven't tried them, just write or call our nearest district office for a working sample and information.

6·WELDING AND CUTTING

Including Brazing, Hardfacing, Riveting and Soldering. For Flame-Hardening, see Section 5.

E. V. DAVID, SECTION EDITOR

Impact Tests of Welded Joints. Part II. Review of the Literature from Jan. 1, 1936 to Jan. 1, 1938. W. SPRAGEN & G. E. CLAUSSEN. *Welding J., N. Y.,* Vol. 17, Sept. 1938. Suppl. pp. 8-27. A 4-page summary condenses the details of the extensive review which covers tensile impact, fillet weld impact, notch and repeated impact. Results of notch impact tests for various steels and regions of welded joint and different welding methods are covered in greatest detail. The literature gives proof of the good impact properties in the heat-affected area of the welding steels, and many cases are cited where higher values than for base metal are obtained. Acceptance specifications for welded structures are in the direction of requiring minimum impact values for welded joints. The effects of C and alloy, O_2 and N_2 on impact are reviewed. For the low alloy steels with low C, the higher impact values of heat affected area than for base metal are particularly noteworthy. The effect of annealing, weld procedure and properties at low and elevated temperatures are detailed. The data are presented as tabulated values and curves. Type and position of impact specimens are illustrated. 175 references. WB (6)

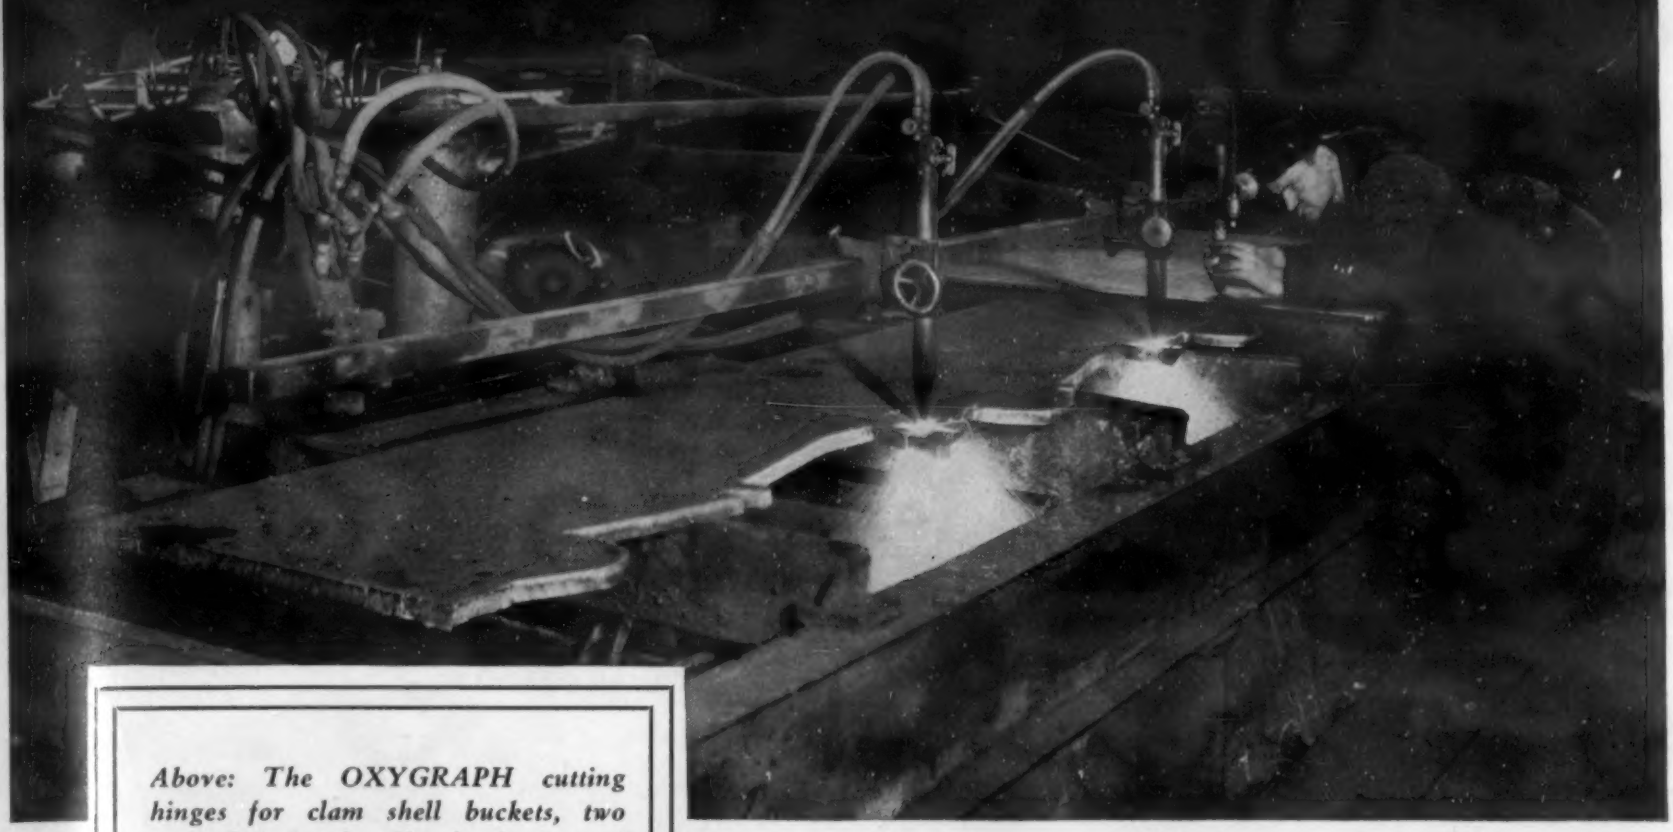
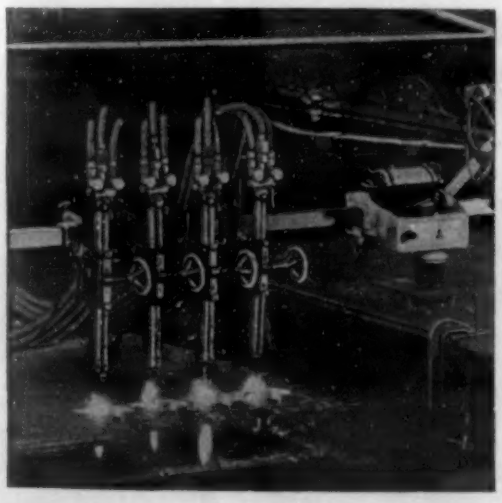
An Analysis of Heat Effect in Welding. W. G. THEISINGER *Railway Mech. Eng.,* Vol. 112, May 1938, pp. 176-181. Research. The effect of welding speed on the hardness of the weld, the heat affected zone and the plate were investigated in plain C and low-alloy steels. The principal harmful effect is the hardening in the metal adjacent to the weld, which sometimes results in cracks in the parent steel. The hardness increases noticeably with increasing welding speed; in a 0.17% C steel the Brinell hardness was 125 up to 6 in./min., increasing sharply to 160 at 8 in. and then more gradually to 220 at 18 in./min. The factors that govern the heat-affected zone are the base-metal composition, welding speed, heat energy applied and base-metal cross-section; the hardness increases with increasing C content. The hardening effect is more pronounced in low alloy steels. A low C content is helpful as it decreases the hardness materially at any welding speed. Sets of curves show this effect clearly for Ni, Cr and Mo steels. C-Mo steels can, however, be very easily welded; Mo substantially aids the weldability of steel and keeps the hardening effect in the affected zone adjacent to a weld extremely low. Ha (6a)



Welding Silicon Steels—A Review of the Literature to July 1, 1937. W. SPRAGEN & G. E. CLAUSSEN. *Welding J., N. Y.,* Vol. 17, Sept. 1938, Suppl. pp. 1-7. The review includes a summary, introductory discussion from the data on physical properties, recovery and pick up of Si in welding, fusion welding properties, resistance welding, forge welding, flame cutting. There appears to be no difficulty in obtaining high strength welds in 1-2% Si steels, but with only fair ductility. The recovery of Si in the weld is dependent on the C content and range of Si of the rod, recovery increasing with C and Si content. Difficulties in welding Si steels (more than 1% Si) and "silicon structural steels" (less than .45 Si and 1.0 Mn), due to cracking and poor fusion, are detailed, showing some inconsistencies in the literature. 66 references and 5 suggested research problems are appended. WB (6a)

Application of Arc Welding in Ship-building (Die Anwendung der Lichtbogenschweissung im Schiffbau) FRANZ CLAASEN. *Werft, Reederei & Hafen,* Vol. 19, Sept. 15, 1938, pp. 273-275. Up-to-date review. The occurrence of cracks in the welds or their vicinity during assembly are frequently due to a local accumulation of too many welds and subsequent heat stresses. The application of strengthening plates is not recommended as a remedial measure since new heat stresses are introduced. Plain welding rods and cored rods *(Seelenelektroden),* but not coated ones, are used for structural steels St 42 and St 52. As to welded tankers, the difficulties due to corrosion attack of gasoline on welds have not yet been completely solved. EF (6a)

Thermal Disturbance During Welding—Considered in Relation to the Hardness of Arc Fillet Weld Areas in Steel. Part II. T. B. WILKINSON. *Trans. Inst. Welding, London,* Vol. 1, Oct. 1938, pp. 227-234. Original research. Establishes the relation of the Bain S-curve to the transformations occurring in the overheated parent metal adjacent to the weld bead. The author devotes considerable discussion to a review of the data on experimentally determined cooling rates (given in tables and curves) for fillet welds in the Reeve type of weld cracking test, as related to heat impact and position of thermocouples in both legs of the fillet. The practical assessment of approximate cooling rate by observation of temper colors was established by comparison with thermal cycles previously determined and by comparison of maximum Vickers hardness values obtained in the heat affected area. The effect of chemical composition and heat input (increasing current) on the maximum Vickers hardness and decomposition products in the microstructure is discussed and data given in tables and curves. Consideration of the Bain S-curve characteristics for a certain chemical composition of steel is brought into the discussion by implying that the high quenching temperature, the resulting grain growth next to the weld bead and the alloy or C contents result in considerable austenite stability for the overheated parent metal. The transformation of austenite may take a long time under these conditions and the possibility of obtaining soft, high temperature transformation products exclusively; hard, brittle, low temperature transformation products or mixtures of the 2 products, depending upon heat input during welding, preheat and chemical composition of the steel, are indicated by the author by superimposing the thermal cycles of the heat affected zone on the Bain S-curve. Some quench tests were made on a series of steels by heating small specimens to 925° C. and quenching in a PB bath at 500° C. for 10, 20 and 40 seconds. Other quench tests were made by heating larger specimens with arc deposited weld metal and quenching in the same way. The conclusion from these tests was that the metallographic structures could be reasonably correlated with the heat treatment undergone and that the 20-sec. stay in the quenching bath was critical for assessing the relative rates of austenite transformation for the various steels. Some tests are reported for welding carried out at 200° C. preheat with different sizes of weld, and maximum Vickers hardness reported. The results indicate that a large weld made at room temperature may result in less hardening than a smaller weld with 200° C. preheat; therefore, it is desirable to indicate the size of the weld when statements are made respecting the decreased hardness resulting from preheat. Preheating to 200° C. is considered to ensure freedom from weld cracking since the austenite may transform to martensite over a long period of time at this temperature. For Part I, see *Metals and Alloys,* Vol. 9, Nov. 1938, p. MA 654L/7. WB (6a)



Welding of Steel St 52 in Shipbuilding (Ueber das Schweissen von St. 52 im Schiffbau) RAPATZ. *Werft, Reederei & Hafen,* Vol. 19, May 15, 1938, pp. 136-138. Original research. Increasing the tensile strength from 53,000 lbs./in.² (Steel "St 37") to 74,000 lbs./in.² (Steel "St 52") by applying more alloy additions rather than higher C content, introduced new problems and difficulties in welding. The following maxima in St 52 cannot be exceeded: 0.2% C, 0.5% Si, 1.2% Mn, 0.55% Cu, 0.4% Cr and 0.2% Mo. Cracks occurring in weld and parent metal of structural steel St 52 are due to excessive hardening of parent metal or weld to, say, 400 Brinell instead of 200-250 Brinell, or are due to defective welds. This may be offset by careful selection of St 52 grades of steel that may differ considerably in chemical composition, and by using larger electrodes for heavy sheets. By specifying "deformable welds," the safety of the weld is by no means assured, particularly in vertical and overhead welding so much employed in ship-building. Unreasonable demands as to ductility, impact strength and bending angle are unnecessarily severe restrictions that insure against neither higher static nor dynamic loads. A critical comparison between coated and cored electrodes *(Seelenelektrode)* is made. The latter have gained a predominant position in German ship-yards. EF (6a)

SIMULTANEOUS MULTIPLE CUTTING with the AIRCO OXYGRAPH . . .

Above: The OXYGRAPH cutting hinges for clam shell buckets, two at a time in the Cleveland plant of WELLMAN ENGINEERING CO. — one of many OXYGRAPH users who have cut welded construction costs by simultaneous multiple cutting.

Below: The OXYGRAPH cutting four parts simultaneously. Remember — AIRCO is ready to help you get the most out of machine gas cutting.

. . . cuts Welded Construction Costs

The AIRCO OXYGRAPH is one of AIRCO's comprehensive line of oxyacetylene cutting machines that have made welded construction practicable by providing the means for cutting large and small parts to shape *economically*.

Where quantities of parts are required, the OXYGRAPH or the TRAVOGRAPH opens the way to further reduction in costs by making it possible to cut two or more of the same parts *simultaneously*.

And once the extra torches are mounted and positioned—which can be done by any competent operator in a few minutes —it's just as easy to cut two or more parts as it is to cut one. Exact duplication is assured.

The OXYGRAPH and TRAVOGRAPH BULLETIN, fully illustrated, gives you the details. WRITE for a copy—today.

AIRCO *Anything and Everything for* GAS and ELECTRIC ARC WELDING and GAS CUTTING WILSON

THIS versatile alloy is spreading its effectiveness to more and more types of work. It makes no difference whether the joints are between ferrous or non-ferrous metals, the same speed and soundness of joint are obtained.

An example is the Sylphon Bellows illustrated, manufactured by Fulton Sylphon Co., Knoxville, Tenn. The heads are EASY-FLO brazed to Monel Metal bellows. EASY-FLO proved ideal for this purpose because:

- It makes strong, ductile joints that withstand continual expansion and contraction.
- It provides corrosion resistant joints.
- It is so free-flowing that the small amount needed is an assurance of economy.
- Its low working temperature reduces to a minimum the annealing and weakening of the thin bellows metal.

If the joining of Monel or any ferrous or non-ferrous metal enters into your production work, get the facts about EASY-FLO and the savings it makes possible. Write today for Bulletin 10-2MA.

● *For best results always use the low temperature HANDY FLUX with EASY-FLO.* ●

Tests of Welds in Alloy Steels. S. F. YASINES & F. C. FAIR (N. Y. Univ.) *Welding J., N. Y.,* Vol. 17, Sept. 1938, Suppl. pp. 28-33. Research to determine (1) relative hardness and impact strength of weld, heat-affected zones and base metal; (2) existence of relation between hardness and impact of various critical sections; (3) effect of heat treatment on weld and heat affected zones; (4) relative merit of 2 kinds of electrodes. Four different grades of steel were welded and tested in "as-welded" and stress-relieved condition for impact of parent metal, weld root, and inner and outer zone of heat affected area. No definite relation exists between hardness and impact resistance since some of the weld and inner and outer zones showed impact resistance following hardness trend, while other tests showed an inverse relation. Stress relief treatment gave slight improvement of impact strength of welds and heat-affected zone. WB (6a)

Field Practice in Welding Oil Well Casing. HOWARD L. NEWBY. *Welding J., N. Y.,* Vol. 17, Sept. 1938, pp. 17, 19. Review of requirements of casing pipe in tensile, compressive and impact strength, and description of method of producing the welded joint. Butt joint is produced with full penetration, no more than 1/32 in. internal bead and no more than 1/8 in. crown. Use of clamp for bringing ends of pipe together permits making accurate welds at a rapid rate. WB (6a)

Light Weight Passenger Coach Frame—Welding Design and Procedure Used in Construction. A. E. KATZ. *Can. Metals Met. Inds.,* Vol. 1, Nov. 1938, pp. 295-298. Descriptive. The changes in design and construction are dealt with sectionally as follows: Choice of machine, electrodes and operations, underframe layout and assembly, super-structure and sheathing, and final finishing. Welding operations include downhand-, butt and fillet-, plug- and butt-welding. WHB (6a)

6b. Non-Ferrous

Cold Welding of Silver. ALLISON BUTTS & G. R. VAN DUZEE (Lehigh Univ.) *Trans. Electrochem. Soc.,* Vol. 74, 1938, Preprint No. 32, 10 pp. Original research. 2 Ag surfaces in contact with each other were welded together at temperatures between 200° and 400° C. by application of a high pressure for a certain length of time. The welding is brought about by the interdiffusion of Ag atoms across the boundary. The surfaces were considered welded if the 2 strips could not be separated without tearing. The pressure required for welding was obtained in 2 ways: (1) By passing through rolls; and (2) by applying a static pressure. To secure a weld by method (1), the Ag strips heated to 400° C. were passed through rolls and received a 50% reduction in thickness. At lower temperatures, one pass through the rolls produced a slight adherence which could be converted into a good weld by further reduction in the rolls, no further heating being necessary. Method (2) consists in applying a pressure of 23,000-45,000 lbs./in.² to Ag strips heated to 200-400° C. Welds were not obtained below 200° C. The welded specimens were only 20-25% as thick as the original strips. As the temperature of welding was increased from 200 to 400° C., the time necessary to produce a weld decreased from 16 hrs. to 0.5 hr. Also, at 400° C., the higher the pressure, the shorter was the time required to produce a weld. The bonding obtained by method (1) was better than that obtained by method (2). The Ag surfaces for welding by either method were prepared by the use of polishing paper. Films of metal oxides, charcoal, oil, grease, etc., did not materially lessen the adherence; graphite and talc slightly lessened the adherence. AB (6b)

Novel Welding Method for Thin Aluminum Sheets (Neues Verfahren zum Schweissen dünner Aluminiumbleche) E. HERRMANN. *Tech. Zentralblatt prakt. Metallbearbeit.,* Vol. 48, Oct. 1938, pp. 731-734. Original research. Describes Weibel's welding method in which 2 C electrodes are heated by means of a low-voltage a.c. The degreased edges of the Al sheets to be joined are edge-bent at right angles for 2-3 mm. and placed in juxtaposition. The backside is coated with a welding flux. The C electrodes are placed on the 2 sheets. Because of the short-circuiting, the tips of the electrodes become increasingly hotter until in 10-15 sec. the metal begins to liquefy. The welding speed is 500-600 mm./min. A 3 mm. diameter wire may be placed between the electrodes for a butt weld. For a sheet of 0.2-0.3 mm. thickness, a current of 50 amps. and 3-4 volts is used, while a 2 mm. sheet calls for 300-400 amps. and 7-8 volts. The heat is quite localized and no arcing occurs, owing to the low voltages used. A table shows the author's tensile tests on Al-Mg-Mn sheets welded according to the new method; the weld is finished in various ways and shows remarkable strength. Several microstructures of Al-alloys welded by the Weibel method and the distribution of hardness across a weld are shown. Welding of sheets of pure Al of 0.2-2.0 mm. thickness was successful and also tests with Al-Mn, Al-Mg-Mn, Al-Mg, Al-Mg-Si and Al-Cu-Mg. EF (6b)

PAGE Hi-Tensile "G"

where ductile, shock-resisting welds are needed

● **Welds made with Page Hi-Tensile "G" electrodes have remarkably high ductility. They stand shock and strain. They are welds that are more than merely strong.**

These superior welds are run at very high speed. The bead is surprisingly smooth. The rod operates quietly, with little spatter. It is used with advantage on production, maintenance and construction work.

H. S. RAWDON, SECTION EDITOR

Protection of Magnesium against Corrosion (La Protection du Magnesium contre la Corrosion) J. FRASCH. *Métaux & Corrosion,* Vol. 13, May 1938, pp. 91-94; June 1938, pp. 115-120; July 1938, pp. 132-137. Practical. Mg becomes covered in air with Mg hydrate, which changes to the basic carbonate, which is porous and non-protective. Mg is more corrodible as it becomes purer. Cast Mg alloys are more corrodible than rolled alloys. Electrodeposited Cu on Mg is porous and does not protect against corrosion. As with Al, surface oxidation of Mg offers protection. Chemical oxidation is principally obtained by the action of solutions of chromates, titanates, manganates, molybdates, tungstates or vanadates. Mg (OH_2) is obtained by the simple action of steam under 5-10 lbs. pressure. Electrolytic oxidation with alkaline salt solution does not offer good protection. On using 2-10 volts in 5 to NaOH solution, the oxidation is violent and the oxide or hydrate film is porous and non-adherent. But by using for 10-40 sec. a current density of 0.4-0.6 amps./dm.^{2} with 10-20 volts in 1% NaOH, a strong and adherent film is obtained. Addition of Na_2SiO_3 to NaOH solution produces on Mg alloys a film that is less porous than that formed when only NaOH is used. Vitrification of this film insures corrosion resistance of Mg alloys. Such films are formed by using 40-50 volts at 15 amp./dm.^{2} and a bath of 1% NaOH and 5% Na_2SiO_3. GTM (7)

7a. Electrolytic Methods

Production of Electro-deposits on Aluminium and Its Alloys. *Light Metals,* Vol. 1, Oct. 1938, pp. 314-316; Nov. 1938, pp. 368-371. Review. The electrodeposition of metals on Al is a difficult and often uncertain process owing to the oxide film of Al_2O_3, always present on the surface of Al and its alloys. Jirotka developed a process which made use of the oxide film. In this method, an artificial film of Al_2O_3, was formed on the work in the presence of heavy metals that were simultaneously deposited. The Al_2O_3 coating probably aided in retaining the heavy metals on the plating surface by a mechanical inter-meshing or perhaps by being impregnated by the heavy metals. Considerable effort has been expended in the development of special electrolytes. One of the more successful plating baths is due to Govaerts, who worked with thiosulphates. The original bath has been considerably modified according to subsequent patents, but it is essentially a solution of heavy-metal thiosulphates in alkaline thiosulphate with an organic acid, often acetic acid, added until sulphur starts to precipitate. This bath has been suggested as suitable for deposition of Cu, Ag, Pb, Fe, Ni and Zn on Al or Al alloys. There is no information available as to the actual degree of success attending this method, but it is known that more or less satisfactory deposits are possible, especially on pure Al. Deposition on Al alloys has not been so successful, particularly if the alloy contains Si and Cu. The Aluminium Industrie A.G. has developed a molten electrolyte process for depositing Al on finished work in Al alloys where cladding is impossible. Deposition of the Al as flakes is prevented by co-deposition with another metal of a similar solution potential. Suitable metals for this purpose are Mn, Cd, Cr, Zn, Cu and especially Pb. The temperature of plating is, of course, below the m.p. of Al. The electrolyte contains a halide of Al with alkaline and alkaline earth halides. A suitable mixture consists of 75% $AlCl_3$, 15% NaCl and 10% KCl. An Al anode is used. The high temperature of the bath, 400-500° C., promotes a firm bond between the 2 surfaces. Ag may be plated on Al and Al alloys by first brushing a concentrated solution of $AgNO_3$ on the surface, and then heating the surface to decompose the salt to Ag. The anodized surface is not always necessary; immersion in a 3% NH_4Cl, 1% NH_4NO_3 solution will produce a film of oxide sufficiently thick for the purpose. The Elytal process of electroplating Al, which stipulates the formation of a partially porous oxide film on Al basis metal, was originally proposed for Cu-plating the contacting surfaces of Al bus bars. Such Cu-plated bars, when joined properly by screws or rivets, have a resistance at the joint of 25 x 10^{-6} ohm/cm.^{2}, while a similar joint in Al has a resistance of 500 x 10^{-6} ohm/cm.^{2} High current densities for short periods of time are used to give the proper type
3 of oxidized surface for plating. The plating metal is supposedly held in place by a keying action of the irregular patches of the oxide film. In another process, the surface is first treated anodically, then cathodically, to obtain a layer of brass, and then cathodically again to produce the final desired coating. The intermediate layer, in this case brass, is plated on with a fairly high voltage, in order to break through the oxide film built up in the anodizing treatment. This treatment probably results in a surface condition somewhat similar to that described for the Elytal process.
4 It is suggested that the anodizing bath contain the desired metal salts so that the same bath could be used cathodically for the preliminary plating, thus saving space and equipment. One type of pre-oxidation treatment uses chlorine-free sodium carbonate. Ag may be plated directly on Al by pickling the Al in a strongly acid solution of HCl, HF and HNO_3, and then in an alkaline bath of 10% NaOH saturated with NaCl. Ag may be plated to withstand repeated bending without peeling. The use of electro-plated architectural components is suggested, particularly Cr-plate.

Anodic Behavior in Cyanide Copper Plating Baths. HAROLD J. READ (Univ. Penn.) & A. KENNETH GRAHAM. *Trans. Electrochem. Soc.,* Vol. 74, 1938, Preprint No. 1, 13 pp. Original research. The anodic polarizations of Cu and Fe anodes were measured in cyanide Cu baths of different compositions. In the plots of anode-polarization *vs.* current density, there were 2 points at which abrupt increases in polarization occurred for relatively small increases in current density. The first point occurred at a
6 polarization voltage of 0.6 v. and a current density of 6-12 amp./ft.^{2}, and the second point occurred at a voltage of about 1.6 and a current density of 10-20 amp./ft.^{2} These points of inflection of the curves are considered to represent a change in the anode reaction from cuprous to cupric. An increase in concentration of free cyanide or of copper cyanide increased the critical current density at which the points of inflection occurred, but an increase in tartrate concentration decreased the critical current density. Hydrogen-ion concentration did not have much effect on the criti-
7 cal current density except in a bath containing 9 oz./gal. of Na_2CO_3. Increase of pH in this bath caused the Cu anode to behave as an insoluble anode, *i.e.* the critical points were absent, excessive polarization did not occur at high current densities, and the Cu anode did not dissolve. When a Cu anode and an Fe anode were connected together and placed in the bath, and the current density gradually increased, most of the current flowed through the Cu anode until the first critical point was reached, at which point some current also flowed through the Fe anode.
8 The values of the polarization voltage and current density on the Cu anode at which the critical points occurred were not affected by the presence of the Fe anode. AB (7a)

Solvent Degreasing in the Plating Industry. H. R. NORGREN (Detroit Rex Prod. Co.) *Monthly Rev. Am. Electroplaters' Soc.,* Vol. 25, Oct. 1938, pp. 731-739. Descriptive. The vapor type degreaser does not remove insoluble matter from the surface. To accomplish this, the surface is sprayed with solvent at pressures of 25-30 lbs./in.^{2}, and in quantities of 80-120 gal./min. The solvent
9 degreasers may be used in connection with automatic or semi-automatic plating systems. The solvent most commonly used is trichlorethylene, and it is stabilized against decomposition by proprietary substances. The average cost of cleaning by this method is $0.70 per ton of work. AB (7a)

Hard Chromium Plating (Die Hartverchromung) OSKAR KRÄMER. *Metallwaren-Ind. Galvano-Tech.,* Vol. 33, Oct. 1, 1938, pp. 411-422. Up-to-date comprehensive review. Among the 22 illustrations are diagrams showing the limiting temperatures and
10 current densities for bright Cr plating and current yield in relation to current densities and bath temperature for 5 plating solutions. Macrostructures of various Cr deposits are shown. Numerous commercial applications of hard Cr plating are discussed. EF (7a)

Electroplating of Tin Plate. Tin as a Basis for Nickel and Chromium. A. W. HOTHERSALL & C. J. LEADBEATER. *Metal Ind., London,* Vol. 53, Nov. 4, 1938, pp. 447-451. Original research. Sn-plate, electroplated with Ni or Cr under industrial conditions, was sometimes sufficiently adherent to enable the material to be worked; the maximum adhesion obtainable is the resistance to rupture offered by the Sn film. Mild steel tensile test specimens were electrolytically Sn-plated, then plated with Ni or Cr. Tensile stress was applied at an approximate uniform loading rate of 0.03 tons/min.; the breaking stress was observed and the adhesion in tons/in.^{2} calculated. Numerous tests were made to determine relative merits of various methods of cleaning. For degreasing Sn-plate, it was found advantageous to apply some form of solvent (vapor degrease) followed by a cathodic treatment in sodium carbonate (50 g. Na_2CO_3/l., 50-60° C., 50 amp./ft.^{2} and 5-10 min.). Anodic treatments that produced a visible oxide film on the Sn surface appeared to promote better adhesion than when only cathodic cleaning was used. An anodic solution of either ammonium citrate or sodium carbonate gave good results (30 amp./ft.^{2}, 4 min. room temperature). Following the anodic treatment, 0.00004 in. Cu was applied from a cyanide solution and followed by Ni-plate. The adhesion increased with the thickness of the Sn-plate, probably because irregularities in Sn-plate thickness caused uneven stress concentrations during tensile tests. Cu-Ni deposits showed better adhesion to thick Sn coatings than Ni deposits. Adhesion was reduced by buffing the Sn (probably because of locally drastic thickness reductions), especially if the anodic treatment were omitted. This effect was more pronounced, the thinner the Sn coating. Tests on Ni over Sn showed that Ni had a definite tendency to produce flaking and cracking. To secure the highest possible adhesion of Ni deposits to Sn surfaces, it was desirable to prevent access of H to the Sn, which was accomplished by use of either a Cu undercoat or an anodic treatment prior to deposition, or a combination of the two. Substantial reduction in porosity was obtained with thin Ni coatings. Also, the Ni-plated Sn-plate showed less porosity than sheet steel coated with Ni of corresponding thickness. The results of tensile and reversed bend tests on Sn-plate after cathodic cleaning and coating with Cu-Ni-Cr deposits showed a negligible effect of plating on the mechanical properties of the Sn-plate base, and even this disappeared in about 1 hr. Ni-plate showed embrittlement after Cr-plating which appeared to be due to H, as it could be removed by heat treatment or prevented by coating the Ni with Cu (0.00002 in.), and was still apparent after removal of the Cr. Sn-plate with a Cu-Ni-Cr deposit, 0.0003 in. thick, retained satisfactory appearance on deformation except when bright Ni was used. When the thickness was increased to 0.001 in., cracking was obvious. The Sn coating becomes porous on deformation and the probability of coincidence of cracks in Ni and discontinuities in Sn is great. The protective value of Cr plated directly on Sn-plate was most damaged by bending over a diameter of 0.06 in. or less. The protective value of direct Cr 0.00003 in. thick after fabrication appears to be superior to that of Cu-Ni-Cr coats. Sn-plate coated with Cr only to a thickness of 0.00003 in. has been pressed into cup shapes without flaking or noticeable cracking. RWB (7a)

A New White Brass Plating Process. FLOYD OPLINGER. *Metal Ind., N. Y.,* Vol. 36, Nov. 1938, pp. 513-516. Descriptive. White alloy deposits containing Zn and Cu in approximately 3/1 ratio are readily produced by plating process. The coatings are smooth, fine-grained and semi-bright, and may be buffed to a high lustre resembling Cr plate. Buffed samples are resistant to tarnish and finger staining, and are easily cleaned. The following bath composition is used: Zinc cyanide 8-10 oz./gal., copper cyanide 1.85-2.4 oz./gal., sodium cyanide 11-13 oz./gal., caustic soda 8-10 oz./gal. and sodium sulfide 0.05-0.1 oz./gal. Operating and control features are discussed. Salt spray life of deposits is proportional to the thickness of the plate. CBJ (7a)

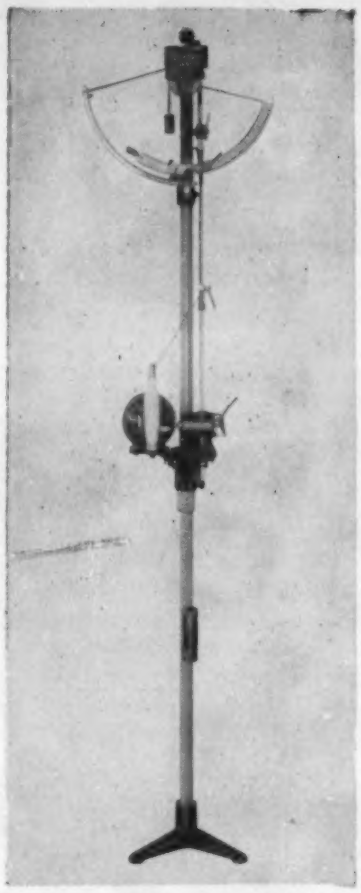
Plating Zinc Alloy Die Castings Commercially. Part III. E. A. ANDERSON (N. J. Zinc Co.) *Metal Cleaning Finishing,* Vol. 10, Oct. 1938, pp. 679-684. Review. In the plants visited, Ni plating solutions were purified by the customary procedure of precipitating the Zn by increasing the pH, and pitting was prevented by oxidizing agents. Practically all plating racks used were of Cu or brass insulated with rubber or lacquer. Electrical connection to the work was made by spring contact, rather than by gravity contact. Defective Ni coatings were removed in most cases by the usual H_2SO_4 anodic strip. For Part II, see *Metals and Alloys,* Vol. 9, Nov. 1938, p. MA 660 L/6. AB (7a)

Plating Aluminum for Appearance and for Wear Resistance. R. F. YATES. *Product Eng.,* Vol. 9, Dec. 1938, pp. 481-482. Practical note. A very firmly adhering coat of Ni on Al is obtained by first anodizing the latter in a bath of oxalic acid, then modifying this coat in a solution of a chemical [not named] so that the article can be plated in a bright Ni bath or in either hot or cold gray Ni baths. A Cr deposit may be put on the Ni when required. The process is applied especially to small articles (hinges, handles, etc.) that must later be soldered. Ha (7a)

Filtration of Electroplating Solutions with Celite Filter Aids. RICHARD J. AMBERG (Johns-Manville Sales Corp.) *Monthly Rev. Am. Electroplaters' Soc.,* Vol. 25, Oct. 1938, pp. 741-747. Descriptive. Celite filter aids, which are diatomaceous earths of different degrees of fineness, prevent slimes from clogging filters, by forming a porous cake, and thus increase the rate of filtration. The clarity of the filtrate can be controlled by the fineness of the Celite. The filter cloth is first covered by a precoat which is formed by passing a suspension of Celite through the pump, about 10 lbs. Celite/100 ft.^{2} of filter surface being required. For filtering a plating bath, about ¼ lb. of Celite/100 gal. is used. The filter aid is either suspended in the plating solution, or the slurry, contained in a separate tank, is injected into the intake side of the pump as it sucks in the plating bath. Centrifugal pumps are preferable since they give a steady flow free from pulsations. The filter aid does not erode the pumps. The cost of filtration at the rate of 40 gal./hr. is $0.30/day, and, at the rate of 8,000 gal./hr., is $3.00/day. AB (7a)

Black Chromium Coatings (Schwarzverchromung) R. LIEBETANZ. *Metallwaren-Ind. Galvano-Tech.,* Vol. 33, May 15, 1938, pp. 220-221. Original research. Standard Cr plating solutions (250 g. chromic acid, 1.25 g. H_2SO_4/1000 cc. H_2O) furnish even at high current densities of 200 amps./dm.^{2} only dark-gray deposits. A great number of plating baths (compositions are given) were tried out at various temperatures and current densities. The best operating conditions for obtaining a black, adherent Cr coating of 75% Cr and 25% chromium oxide were found to be: 250-400 g. chromic acid, 5 cc. glacial acetic acid/1000 cc. H_2O, at 80-100 amps./dm.^{2} at the cathode, and 25° C. bath temperature. EF (7a)

7b. Non-Electrolytic Methods

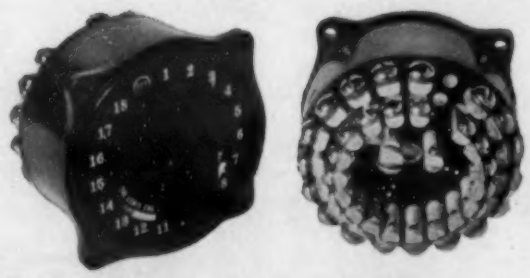


The Application of Polishing and Buffing Wheels. Part IV. ROBERT T. KENT. *Metal Cleaning Finishing,* Vol. 10, Oct. 1938, pp. 694-704. Descriptive. The type of cotton cloth used in the construction of buffs is important. Cloth containing 64 x 68 threads per in. gives a soft wheel suitable for coloring operations, and cloth of the 84 x 92 construction gives a hard buff suitable for cutting-down operations. The yarn used for the cloth should be made of long fibers and spun with a tight twist. 4 types of buff construction are used: (1) Full disc buffs consist of about 20 discs of cloth sewed together in a section. They have good balance, give a high grade finish and have a long life. (2) Sewed piece buffs consist of small pieces of cloth interleaved in layers and sewed together. Since they may be made of waste from the manufacture of full disc buffs they are cheaper but usually do not have the balance or wearing qualities of full disc buffs. (3) Folded buffs consist of folded pieces of cloth overlapped and sewed together. (4) Continuous strip buffs are made by winding a strip of cloth into a circle. Types 3 and 4 are well ventilated and can be used under severe conditions that would char other buffs, and the wavy or puckered edges of the buff prevent the appearance of buffing marks. The method of sewing a buff can affect its performance. In general, the more closely together the rows of sewing, the harder are the buffs. The horsepower required for buffing is approximately 3 h.p. per in. width of buffed surface, when the wheel pressures are 10-15 lbs. per in. of face width. For previous work, see also *Metals and Alloys,* Vol. 9, Nov. 1938, p. MA 661 L/8. AB (7b)

Galvanizing Quality. R. W. SANDELIN (Atlantic Steel Co.) *Steel,* Vol. 103, July 4, 1938, pp. 44, 56, 61. Report of investigation. Appearance of hot-dip Zn coatings on strip or sheet is the criterion of quality used by the inspector in either the producer's or customer's mill. The causes of the dull gray surface spots, so frequently a cause of rejection, were investigated. 20 (commercial, semi-killed) steels were studied: 0.16-0.34% C, 0.31-0.64% Mn, 0.009-0.088% P, 0.024-0.050% S. Dull spots are shown to be areas where the Zn has alloyed with the steel base leaving dull gray Fe-Zn alloy at the surface. Production of gray spots therefore results from (1) any set of conditions that tend to produce a thin coating, such as slow emergence from bath or short immersion time and high bath temperature, or (2) conditions that tend to accelerate diffusion, such as high temperature of emerging strip or warm mill temperature. The most important single factor affecting spotting was found to be the type (not necessarily composition) of steel employed; the influencing factor is the rate of diffusion of Zn into the steel. Neither P nor C content had any significant connection with spotting. Pickling only intensified the spotting or non-spotting characteristics of the steel. Steels that spotted were found, however, to have a much smaller grain size than non-spotting steels, with a carbide structure ranging from normal to slightly abnormal; average grain size, therefore, not normality, is the important factor. Coarse-grained abnormal steels with high dissolved O content were non-spotting as compared with fine-grained normal steels with less dissolved O, which spotted. MS + FPP (7b)

SCOTT TESTERS

An accurate motor-driven, fine wire tensile testing machine, made in capacities up to 20 pounds.



The speed and ease of operation as well as its quietness makes this apparatus excellent for control or laboratory evaluation of small wires.

Made by

HENRY L. SCOTT CO., PROV., R. I.

ROTARY SELECTOR SWITCHES *for use with Multiple* THERMOCOUPLES

There is a "LEWIS ENGINEERED SWITCH" suitable for every multiple thermocouple installation.

Every Switch has an "OFF" position. Every model is designed exclusively for the small voltages generated by thermocouples. Low contact resistance permits very accurate readings. Standard Stock Models.

Part No.	No. of Pos. besides "Off" Pos.	Nominal O.D.	Approx. Wt.
11S	2, 3, 4	2.5"	7 oz.
10S	6, 9, 12, 18	3.0"	19 oz.
12S	24, 28	4.0"	25 oz.

Deliveries within 48 hours from receipt of order. Write for Bulletin 8-9.

Fish Scale Formation in Enamel (Die Fischschuppenbildung im Email) WALTER KERSTAN. Reprint from *Sprechsaal,* No. 27-30, 1938, Verlag der Sprechsaal, Coburg 1938, 61 pp. Original research. The practical opinions of numerous enameling plants are first given. The finest cracks in the enamel are really fish scales of smallest dimensions. All fish scales reach to the sheet surface. Surface cracks may be deepened fish scales. The different sheet brands commonly applied in Germany, made of Armco ingot Fe, open hearth and basic Bessemer steel, were used in the tests after chemical, physical and metallographic examination. The sheets were either normalized or box annealed. The different steel brands showed differences in their tendency to fish scale formation, when applying the same type of enamel. Prolonged pickling brought no increased tendency to fish scaling. Use of pickling inhibitors had no pronounced effect on fish scaling. To a large extent the defect could be decreased by sand blasting the sheets, evidently because of the coarser surface. The furnace atmosphere has a pronounced effect. Reducing atmospheres are highly detrimental. The formation of adhering layers is suppressed by the presence of CO. By suitable mill additions the ground enamel within certain limits can be made more resistant against fish scale formation. The most favorable amount of additions can be determined by experiment in every single case and depends on the composition of the enamel. Enamels inhomogeneously melted develop fewer fish scales. Firing at too high temperature and prolonged firing at high temperature promotes formation of fish scales. 850° C. is the most suitable temperature. Retarded firing at this temperature brings about a completely developed adhering layer but, at the same time, the enamel itself is inhomogeneous. Vacuum-annealed sheets possess much fewer fish scales than those not so treated. However, vacuum-annealed sheets possess fish scales to a large extent when enameled in a muffle with reducing atmosphere. The structural changes in the sheets during enameling may have a bearing on the defect, in that CO is formed through decarburization of the sheet surface. Not only the H_2 absorbed in pickling but also the H_2 developed by H_2O decomposition during enameling has a bearing on fish scale formation. Stresses within the enamel, particularly when caused by layer-like structure of the enamel, may bring about the defect. Crystal formation in the ground coat leads to fish scales, but, by adding alkaline borates to the mill, the defect can be decreased considerably. A finely roughened sheet surface greatly lessens fish scaling. In general, several of the mentioned causes act together simultaneously to bring about the defect. [In the opinion of the abstractor who has carefully watched the progress of this investigation, because of his own personal interest in the problem, Kerstan's investigation and that of Hoff and Klärding (see following abstract) will prove to be classic contributions to the solution of a familiar, yet little understood, enameling problem.—G.N.] GN (7b)

Connection between Gas Evolution and Fish Scaling in Enameling (Zusammenhang zwischen Gas- und Fischschuppenbildung beim Emaillieren) H. HOFF & J. KLÄRDING. *Stahl u. Eisen,* Vol. 58, Aug. 25, 1938, pp. 914-916. Original research. The gases evolved upon heating enamel slips by themselves or mixed with steel chips were determined and found to consist mainly of CO_2, H_2 and steam. During thorough drying, the enamel slips gave off about 1% by weight of chemically combined H_2O. Upon melting the slips, steam and CO_2 are given off. Upon heating a mixture of enamel slip and steel chips to red heat, the steam is decomposed by the Fe, and the H_2 content of the evolved gases rises to over 80%. This H_2 diffuses readily into a steel enamel solidifies. The gas pressure thus set up is considered to be a main cause of fish scaling. The tightness of the enamel and sheet in enameling; on cooling it cannot be given off after the the amount of burning-in play secondary roles. SE (7b)

Pretreatment of Metal Surfaces for Painting. F. N. SPELLER (Natl. Tube Co.) *Ind. Eng. Chem.,* Vol. 30, Oct. 1938, pp. 1152-1156. Practical. Recent tests and experience indicate that, as a rule, the most desirable preparation of steel surfaces for painting, particularly for under-water service, is complete descaling, followed by chemical treatment, such as washing with phosphoric acid-chromate solution. The principal factors that influence adhesion of paint film to metal surface are discussed. The sub-committee (XXIX of Committee D-1) of the A.S.T.M. on Preparation of Iron and Steel for Painting, is recommended as a good group to evaluate all the factors involved. 23 references. MEH (7b)

The Mutual Displacement of Metals from Vapors of their Salts and the Application of this Process in the Fight Against Corrosion. N. A. TZGARISHEW & E. S. SARKISOV. *Zhur. Obshch. Khim.,* Vol. 8, No. 9, 1938, pp. 830-833. In Russian. The precipitation of Cr on Fe from chromium chloride vapor is investigated. A highly corrosion resistant coating is obtained by treatment at 1100° C. in 4 hrs., followed by annealing for 3 hrs. at 875° C. A durable coating can also be obtained by joint precipitation of Cr and Ni, as well as W, from vapors of their salts. NA (7b)

8·TESTING AND CONTROL

Methods and Equipment. Physical and Mechanical Property Testing. X-Ray and Magnetic Inspection. Spectrographic Analysis.

W. A. TUCKER, L. S. REID AND G. R. HARRISON, SECTION EDITORS

The Impact of Beam. ZIRO TUZI & MASATAKA NISIDA. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Oct. 1938, pp. 1053-1079. In English. Original research. (For previous work see also *Metals and Alloys,* Vol. 6, Sept. 1935, p. MA 368 R/8; Vol. 7, June 1936, p. MA 308 L/1.) It was previously found that photo-elastic, experimental results do not coincide exactly with theoretical deductions and that some complicated vibration existed in the specimens. In the present paper, more precise observations on impact phenomena were made. Beams of steel, Cu and Al were supported at both ends and struck at the center by a hammer of different weights and falling from various heights. The displacements of the hammer and the beam were photographed with a high speed rotating camera having a resolving power of 1/80,000 sec. Hammer and beam collided several times during a short duration, which might be regarded as a single blow in classical dynamics. Beam and hammer are never in continued contact. The manner of contact is independent of the material of the beam or of the height of fall, and is affected only by the ratio of the weight of hammer and beam. The experimental results are in disagreement with classical dynamics, but agree with a theory taking into account the free and forced vibration of the beam and the local indentation at contact point. EF (T-8)

Measuring Internal Stresses by Means of X-rays (Messung innerer Spannungen mit Röntgenstrahlen) FRANZ WEVER. *Umschau,* Vol. 42, Oct. 23, 1938, pp. 978-981. Descriptive. The older, mechanical process for determination of internal stresses measures the deflection of pieces whose state of equilibrium was disturbed by a saw-cut or the like. The new method measures the stress directly without damaging the test piece, as elastic deformation of the lattice. It is accurate even if plastic deformation exists at the same time. Its limitation is that it records only superficial stresses. The reflection principle is used. The diameter of the interference circles is compared with that of an unstressed comparative material of known lattice constant, such as Au or Ag dust. Only 3 pictures are needed to determine the size and location of the principal stresses. Practical experience has proved that the X-ray method usually delivers somewhat higher stress values than the mechanical method if the surface is under stress. The mechanical method gives average values over the cross section; they may easily be too low. The X-ray method is therefore more reliable and practical. RPS (T-8)

Suggested New Definitions for Proportional Limit and Yield Point. L. H. DONNELL. *Mech. Eng.,* Vol. 60, Nov. 1938, pp. 837-838. Discussion. The inadequacy of the present definitions, because of present greater refinement in measuring method, is explained and it is proposed to express the stress at which plasticity first appears, the proportional limit, by $\sigma_{p1} = 1.5\sigma_{¼E} - 0.5\sigma_{¼E}$, and the yield point by $\sigma_{y1} = 1.5\sigma_{¼E} - 0.5\sigma_{¾E}$, where $\sigma_{¼E}$ and $\sigma_{¾E}$, respectively, designate the stresses at which the stress-strain slope is ¼ and ¾ of the original slope E. For materials such as structural steels, these formulas give values close to the proportional limit as usually indicated, and to the true yield point. For materials that have no true proportional limit or yield point the formulas give values for points in the stress-strain relation of the material closely approximating actual conditions. The application and usefulness is demonstrated, especially for Al and Al alloys. Ha (T-8)

Determination of Expansion Coefficients by the Powder and Rotating Crystal Methods (Die Bestimmung von Ausdehnungskoeffizienten nach der Pulver- und der Drehkristall-Methode) M. STRAUMANIS, A. IEVINS & K. KARLSONS. *Z. anorg. allgem. Chem.,* Vol. 238, July 1, 1938, pp. 175-188. Experimental. Linear and crystallographic expansion coefficients may be determined with a precision equal to or exceeding that of other methods for temperatures below 70° C. by operating the X-ray diffraction cameras in thermostats in which the temperature is maintained constant to about 0.03° C. The expansion coefficients of various salts and very pure Al were determined and compared with values in the literature. HFK (T-8)

Conversion Relations for Brinell, Rockwell and Vickers Hardness Numbers (Umrechnungsbeziehungen zwischen Brinell, Rockwell und Vickershärtezahlen) H. v. WEINGRABER. *Tech. Zentralblatt prakt. Metallbearbeit.,* Vol. 48, Oct. 1938, pp. 741-742. Original research. The Rockwell C hardness values deviated among themselves to the greatest extent, followed by Brinell hardness numbers determined on different machines. The deformation of the steel balls is blamed for this. Using a tungsten carbide ball improves the reliability of the readings considerably. The harder the test piece, the smaller the penetration of the Rockwell diamond cone and the greater the error due to slight variations of the contour of the tip of the penetrator. The author presents in graphical and tabular form conversions for all 3 hardness scales; the following formula covers the Brinell H_n and Vickers hardness H_p units only: $H_n = H_p$ (for H_n equal to or less than 300), $H_p = 1.2\ H_n - 60 = 1.2\ (H_n - 50)$ (for H_n equal to or more than 300), and $H_n = 0.83\ H_p + 50$ (for H_p equal to or more than 300). The conversion relations derived are valid for steel only and do not hold for non-ferrous metals. EF (T-8)

Gamma Radiation for Non-destructive Testing of Materials (Die Gammadurchstrahlung als zerstörungslose Werkstoffprüfung) O. TH. KORITNIG. *Oberflächentech.,* Vol. 15, Oct. 4, 1938, pp. 189-190. Review. The effect of γ radiation from radioactive elements is stronger than that of X-rays, for γ-rays have a shorter wave length and, therefore, greater penetrating power. Cu alloys of about 150 mm. and steel of 200 mm. thickness can be examined with them and still show defects clearly, but require exposures up to 100 hrs.; the distance of the sample from the source of radiation is about 70 mm. The procedure is explained in detail, and means for shortening the time of exposure are discussed. The present most-used radioactive element is mesothorium, as it is cheaper than Ra. The γ-radiation method is recommended only for pieces of large dimensions. Precautions to be observed both in evaluating the film and for protection against the harmful physiological effects of the rays are briefly mentioned. Ha (T-8)

New Manual Hardness Tester (Neuer Handhärteprüfer) *Tech. Blätter,* Vol. 28, Sept. 18, 1938, p. 560. Description of a new patented Rockwell hardness tester, developed by Dr. Müller of Focke-Wulf Airplane Works at Bremen, that weighs 1 kg., making possible hardness measurements on large pieces that cannot be tested by rigidly located hardness testers. Vickers determinations can also be made with this apparatus. [The abstractor tried one of the first models of this new apparatus and found the hardness readings in good agreement with other modern Rockwell hardness testers, such as the German tester made by Reicherter, Esslingen.—G. N.] GN (T-8)

Theories and Experiences on the Internal Damping of Materials (Teorie ed esperienze sullo smorzamente interno dei materiali) R. GIORANNOZZI. *L'Aerotecnica,* Vol. 28, Oct. 1938, pp. 1095-1133. Mathematical discussion and correlated abstract of published work on damping. The bibliography is to be published later. It is necessary to test materials in exactly the condition of service to secure information of greatest engineering value. HWG (T-8)

Quantitative Spectrum Analysis, in Particular the Determination of Vanadium in Steel (Die quantitative Spektralanalyse, insbesondere die Bestimmung von Vanadin in Stahl) J. WILKEN. *Arch. Eisenhüttenw.,* Vol. 12, Sept. 1938, pp. 133-140. Original research. Suitable lines for determining the V content in steel are given. A spectrograph with high resolution must be used. SE (H-8)

Tension-impact Testing. D. S. CLARK & G. DÄTWYLER. *Mech. Eng.,* Vol. 60, July 1938, p. 559. An arrangement of an Izod pendulum-impact machine in combination with an oscillograph is described that records the tensile forces acting on the specimen during the short time of the impact as electrical voltage changes in a force-time diagram. From this force-elongation and stress-strain diagrams may readily be obtained. Ha (T-8)

Non-destructive Thickness Measurements. *Metallurgist (Suppl. Engineer)* Oct. 1938, p. 165. Brief review, with extended abtract of paper by A. Trost in *Stahl u. Eisen.* See *Metals and Alloys,* Vol. 9, Oct. 1938, p. MA 616 L/6. VVK (T-8)

Quantitative Spectrographic Analysis. Standardization of Technique. D. M. SMITH. *Metal Ind., London,* Vol. 53, Nov. 18, 1938, pp. 485-488. Discussion of standardizational technique and development of methods suitable for routine analysis. The usual modes of excitation of spectra are the arc, spark and flame, or modifications of the same. As a preliminary to chemical analysis, a rapid spectrographic examination may save a considerable amount of trouble. Quantitative analysis may be made by the following methods: Comparison sample, internal standard, auxiliary spectra, auxiliary alloy, synthetic spectra, logarithmic sector, stepped sector and non-recording microphotometer. Each method is described. The analysis of pure metals is still the best example. With the provision of reliable standards for comparison and calibration purposes, it is a comparatively easy matter to standardize a routine method capable of giving results that are more reliable and consistent than those of routine chemical analysis. For routine examination of high purity materials, it is doubtful whether the extra time involved by the use of the microphotometer is justified. Where one is dealing with the third to fifth place decimals, the one significant figure obtained by visual interpretation of the spectra is in all probability a sufficiently definite indication of the information required. In testing to specifications in many cases the only information required is that a certain limit is not exceeded; the spectrograph gives all the information necessary for such work, and the exact composition is unimportant. 28 references. RWB (H-8)

Testing of Clad Steel Sheets (Prüfung plattierter Stahlbleche) W. RÄDEKER. *Stahl u. Eisen,* Vol. 58, Oct. 27, 1938, pp. 1153-1160. Practical. To determine the adhesion of the clad layer, 2 pieces of the sheet were cut and the clad layers strongly soldered together. The base portions were then welded to rods forming a tensile specimen when machined, the 2 bonding surfaces to be tested being toward the middle of the reduced gage length. This afforded a tensile test of the bond between the clay layer and the base. Bend, impact and metallographic tests are also described. SE (T-8)

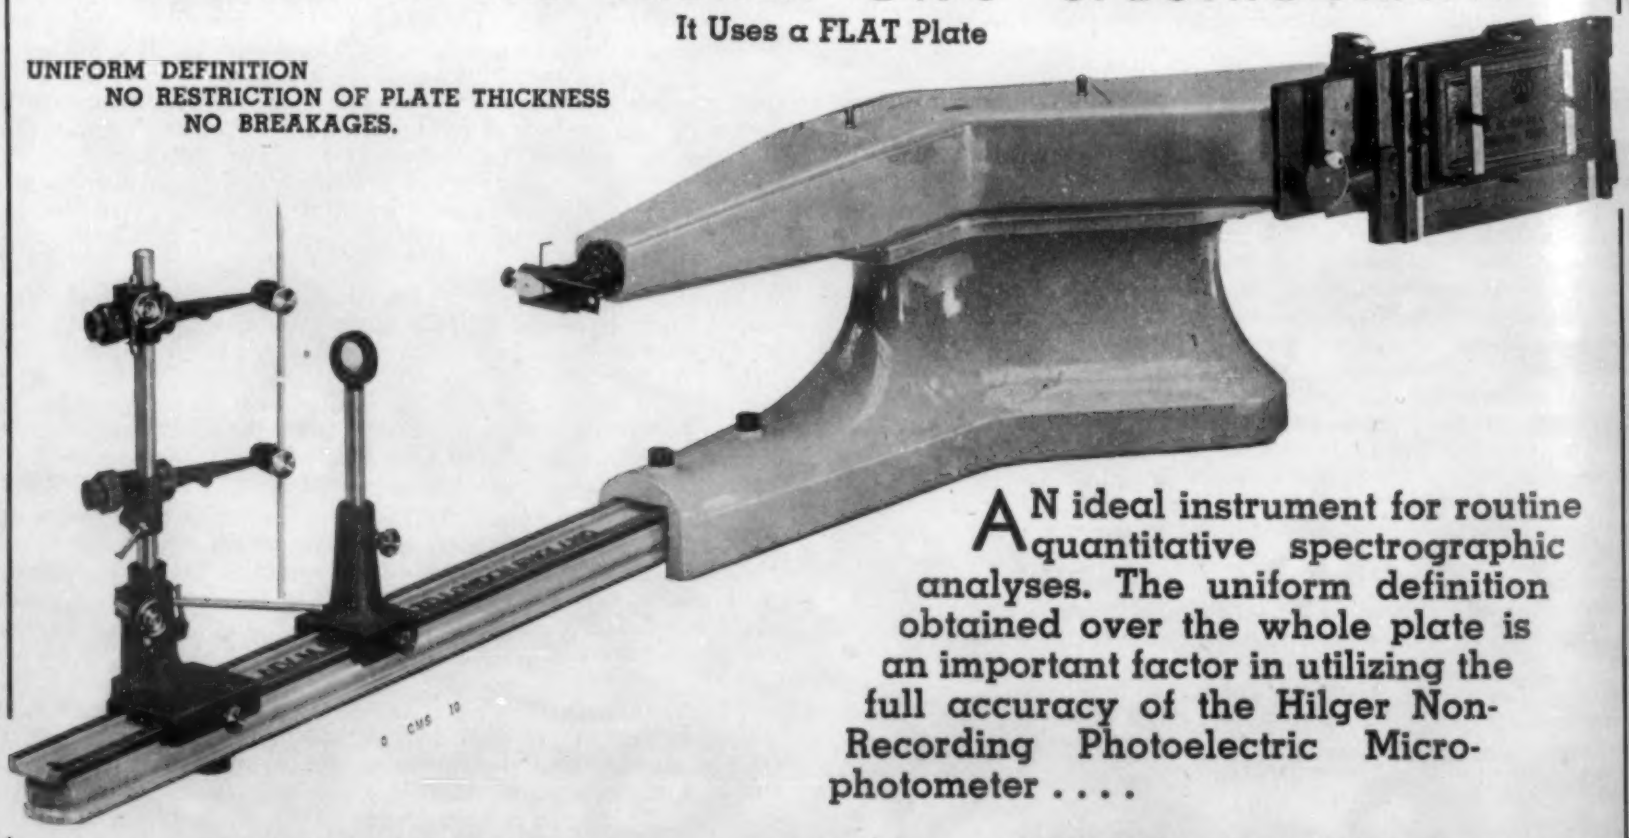
Artificial Radioactivity as a Test for Minute Traces of Elements. G. T. SEABORG & J. J. LIVINGOOD (Univ. Calif.) *J. Amer. Chem. Soc.,* Vol. 60, Aug. 1938, pp. 1784-1786. Research shows how it is possible to detect and identify very small amounts of impurities by means of their characteristic half-lives, after the substance containing the impurities has been rendered radioactive by bombardment with charged particles of high energy or with neutrons. With the help of chemical analysis after the bombardment, impurities present to the order of one part per million can sometimes be detected. A gallium impurity of 6 parts per million was found in a sample of Fe. Without chemical analysis, one part in 1,000-10,000 can usually be detected. MEH (H-8)

8a. Fatigue Testing

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in co-operation with the A.S.T.M. Research Committee on Fatigue of Metals. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Fatigue Bending Strength of Fillet and Butt Welds (Dauerbiegefestigkeit von Kehl und Stumpfnahtverbindungen) A. THUM & A. ERKER. *Z. Ver. deut. Ing.,* Vol. 82, Sept. 17, 1938, pp. 1101-1106. Research. The fatigue strength of sheets of 15 mm. thickness and 500 mm. width, welded perpendicularly to another sheet either by a fillet or butt weld, was investigated, with attention given also to different subsequent treatments. Both types of welds had originally a bending fatigue strength of 13,000-14,000 lbs./in.^{2} Milling in the weld increased the strength to 20,000 lbs./in.^{2} for fillet and to 22,000 lbs./in.^{2} for butt welds. Interior stresses caused by the welding process have a very slight effect on the bending fatigue strength, so that stress-relief annealing resulted in practically the same fatigue strength as the original. Cold-deformation by hammering gave no improvement. The bending fatigue strength of the welded seam worked down to sheet thickness was the same as that of the parent material. Ha (8a)



Effect of Surface Decarburization and Prior Heat Treatment on the Endurance Properties of Stretched Steel Wire (Einfluss von Randentkohlung und Wärmevorbehandlung auf Dauer- und Zeitfestigkeit von Stahlspanndrähten) F. MODERN ANALYSIS

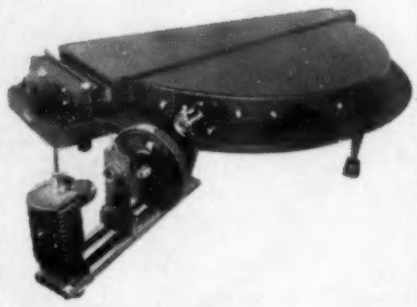
Carbon Determinator



SPECTROGRAPHIC EQUIPMENT

The Applied Research Laboratories Spectrograph is the modern spectrograph.
Low operating cost.
Constant dispersion and excellent resolution over the entire spectrum range.
Spectrogram length — 12½ inches. Camera holds 100 ft. of film, avoids frequent reloading of camera.
High photographic speed with speed control.
Film calibration by step sector. Not sensitive to vibration of building.
Will stay in adjustment.
Minimum of adjustment required saves time and insures reproducibility.
Emission or absorption spectrographic analysis.
Suitable for qualitative and quantitative analysis.

Speed up your laboratory and make it a working tool. Prevent waste by keeping the laboratory in step with production.

Obtain accurate carbon determinations in two minutes with the Carbon Determinator.

Secure accurate, sulphur determinations in five minutes on ferrous and non-ferrous metals and other sulphur bearing materials with the Sulphur Determinator.

Flash Welding of Rails. H. C. DRAKE (Sperry Products, Inc.) *Welding J., N. Y.,* Vol. 17, Oct. 1938, pp. 17-21. Descriptive. A special train is sent out for welding along track. The train consists of locomotive for steam generation, car with 2 turbo generators for welding current, flash welding car, car with furnace for stress-relieving weld and adjacent rail, also grinders for finish grinding weld, and other cars for lining up rail. Rail has been welded in lengths up to 1400 feet. The aim of this process of welding is to produce a joint comparable to the rail itself in hardness, tensile strength, strength under the drop test, and resistance to repeated stress. The question of resistance to repeated stress is considered to be of prime importance in view of the fact that for several years an average of about 10,000 failures or incipient failures from internal fissures are found annually on the railroads of the U. S. and Canada. The fatigue behavior of full-section welded rail joints was determined with an H. F. Moore rolling-load testing machine (see "Progress Report of the Joint Investigation of Fissures in Railroad Rails, *Proc. Am. Ry. Eng. Assn.,* Vol. 36, 1935, pp. 1065-1090; see also *Metal Progress,* Vol. 28, Nov. 1935, p. 46.) This testing machine subjects the rail specimen and the weld not only to bending moment but also to heavy wheel load, which seems the most important factor in developing internal fissures. The development of fissures during a rolling-load test is determined by an electrical drop-of-potential method (the Sperry "hand test"). The effect on resistance to repeated stress of stress relief and removal of flash by grinding was studied. The most effective stress-relieving treatment used was: (1) air cool for 3½ min. after welding, (2) heat to 1250° F. in 3 min. in an oil fired furnace, (3) remove from furnace and cool under an asbestos covering to 600° F. in 20 min., (4) cool in air. Data on rolling-load and other tests are given together with cuts of typical failures.

J. S. MARSH, SECTION EDITOR

Gases and Metals. COLIN J. SMITHELLS. *Foundry Trade J.*, Vol. 59, Sept. 1, 1938, pp. 159-162. Review plus original research. Gases may be present in a piece of metal, as (a) surface gas, (b) blowholes, (c) true solution and (d) in combination. Of the common gases, H_2 is the most readily soluble in a large number of metals. O_2 more frequently gives rise to a definite oxide phase. N_2 is soluble in a limited number of metals, and although there is evidence of simple solubility in some cases, all metals that dissolve this gas are known to form nitrides under suitable conditions. Compound gases can diffuse into metals only after dissociation. As a rule, these gases give rise to at least one compound. The oxides of C may yield both oxides and carbides in the metal, hydrocarbons give rise to dissolved H_2 and a carbide phase, water vapor breaks down to H_2 and an oxide phase. True solution is an endothermic process, and solubility therefore increases as the temperature is raised. Solubility should be related to temperature by an equation. $S = Ce^{-E_S/2KT}$ where C is a constant and exponent E_S represents the heat of solution. X-ray pictures show that as H_2 is absorbed the lattice of the metal gradually expands, and although the exact positions of the H atoms are unknown, they must presumably be interstitial. H_2 does not in any case give rise to a compound that separates as a distinct phase visible under the microscope. When Cu melted in air is allowed to freeze, the excess O_2 in solution is precipitated as a Cu-Cu_2O eutectic, and 2 phases are present in the solid metal. The Ag-O system presents some unusual features. The solubility temperature curve has a minimum at about 400° C., increasing again at both higher and lower temperatures. This means that the heat of solution is positive below 400° C. and negative at higher temperatures, and suggests that O_2 is mainly present as Ag-O below this temperature, and as dissolved O_2 above 400° C. If Ag is first saturated with H_2 and then heated in O_2, it is embrittled, O_2 diffuses-in much faster than H_2 can diffuse-out. In all cases of simple solution the absorption of gases is proportional to the square root of the gas pressure. In cases of compound formation, there will be an upper limit to the solubility, corresponding to the composition MH_n when the metal is saturated, and further increase in pressure will not result in increased absorption. H_2 alone diffuses so rapidly through most metals near their melting points that it can seldom develop as bubbles and blowholes. O_2 alone is usually precipitated as oxides when cooling leads to supersaturation. It is only when both these elements occur together, as they always will in the absence of special precautions during melting, that unsoundness results. An interesting discussion of a rimming steel ingot is given. During the solidification of such an ingot, a considerable amount of gas—CO and CO_2—is evolved and bubbles up through the molten metal. Analysis shows that the gas in the blowholes is mainly CO. AIK (9)

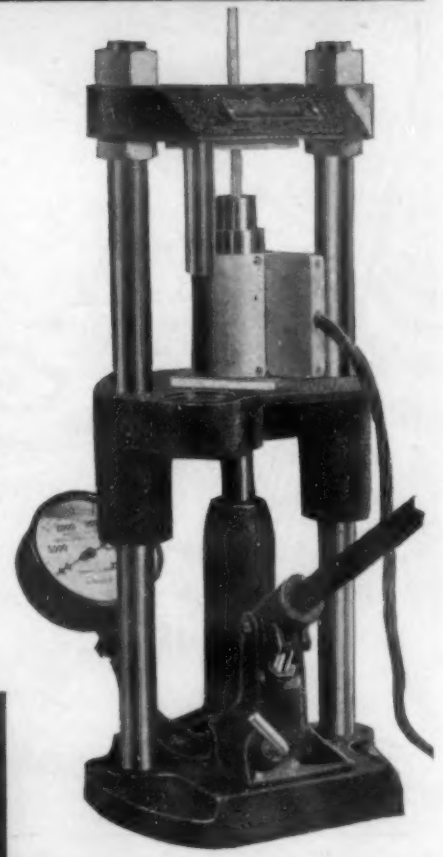
The Super-microscope (Das Übermikroskop) B. v. BORRIES, H. RUSKA & E. RUSKA. *Chem. Ztg.*, Vol. 62, Aug. 6, 1938, pp. 561-565. The super-microscope allows a magnification of 30,000 as compared with 2,000 maximum of an optical microscope. The definition is so good that it allows an additional optical magnification up to 4 or 5 times. The total magnification amounts to about 100,000. The principle of the invention is to work with rays whose wave length is much smaller than the light rays, *i. e.* cathode rays. The "lens-system" consists of coils enclosed in cases shaped like pole shoes, giving very small focal lengths. The rays become visible by change in wave length, which is effected by means of a fluorescing screen. The cathode rays can also be used for exposing photographic film. It is necessary to enclose the object to be investigated, the screen and the light-sensitive plate in the vacuum. Locking the object into the vacuum takes only 1 min., the plate 2 min. Another distinction of the new device is that it shows the distribution of masses, whereas the optical microscope shows the distribution of colors and refraction index. Major fields of application have been in medical and biological research, although the super microscope has been used for investigation of dyes, ores and other pulverulent materials. [Its usefulness in metallurgical research has still to be proved. R. P. S] RPS (9)

Fundamental Processes of Recrystallization in Precipitation-hardenable Alloys (Ueber die Grundvorgange bei der Rekristallisation aushärtbarer Legierungen) H. BUMM & H. G. MÜLLER. *Metallwirtschaft*, Vol. 17, Aug. 26, 1938, pp. 903-910. Original research and theory. A recrystallization study of 7 ternary Fe-Ni-Cu alloys, containing Fe and Ni in the ratio of 59/41 with 0, 1, 2.7, 6.0, 8.1, 10.8 and 13.1% Cu. Coercive force and permeability measurements were used to determine the beginning and progress of recrystallization with X-ray transmission photograms being used occasionally to verify magnetic data. Electric resistance measurements were used to follow the course of precipitation of a Cu-rich phase. After annealing at 1000° C., the alloys were quenched and cold rolled 99% without intermediate annealing. Subsequently, the alloys were annealed at various temperatures from 300° to 850° C. for varying time intervals and tested. The decrease in stress associated with recovery causes a small decrease in resistance and coercive force and a small increase in permeability, while recrystallization sharply increases coercive force as well as sharply decreasing permeability. Slow recrystallization does not affect the electrical resistance, while decomposition of a solid solution does. The beginning of recrystallization was not the same for all alloys; there was a definite incubation period before recrystallization took place at a constant temperature. Once recrystallization had taken place the rate of increase in permeability or decrease in coercive force is a function of grain growth. In general, it was found that with a constant amount of deformation, increasing the temperature would decrease the incubation period for recrystallization and increase the rate of grain growth. As the Cu content of the alloys became higher, the recrystallization temperature and the incubation time were increased, while the rate of grain growth decreased. The alloy containing no Cu recrystallizes at 500° C., while that containing 13.1% Cu recrystallizes above 800° C. A comparison is made between the authors' study and analogous experiments on the recrystallization of salts. On this basis a general theory of recrystallization phenomena is advanced. GA (9)

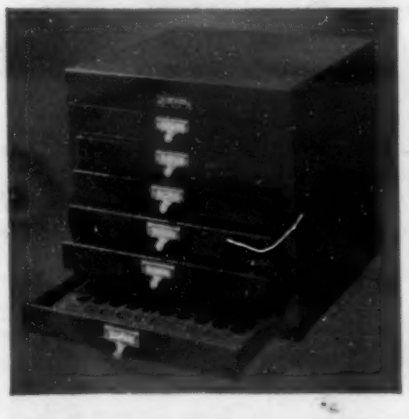
The Crystal Structures of the Iron-palladium Superlattices. RALPH HULTGREN & CARL A. ZAPFFE (Harvard Univ.) *Z. Krist.*, Vol. 99, Aug. 1938, pp. 509-512. In English. Original research. Previously reported structures of FePd and $FePd_3$ are in disagreement with the authors' determinations. Debye patterns of a 51.9 atomic % Pd alloy quenched from above 700° C. show a face-centered cubic structure with atoms distributed at random. At 650° C. and below a tetragonal structure with superlattice was found. At intermediate temperatures, a mixture of the 2 patterns was present. At 600° C., $a = 3.825$ A.U., $c_0 = 3.723$ A.U. and $c/a = 0.9664$. At low temperatures, c/a decreases; c/a also decreases with higher Pd content. It is remarkable that there is an increase of atomic volume on ordering. This may be connected with the change in magnetic properties. The FePd superlattice is more stable with an excess of Pd than at its theoretical composition. At 60 atomic % Pd, it is stable up to 775° C., while the 51.9 atomic % Pd sample decomposes at about 675° C. This is surprising, as perfect order can be present only at 50 atomic %. There is an $FePd_3$ ordered state of the same structure as $AuCu_3$, which is face-centered cubic. An expansion of the $FePd_3$ lattice takes place during ordering. In the disordered state $a_0 = 3.837$ A.U.; in the ordered, $a_0 = 3.840$ A.U. It also is not most stable at its theoretical composition; at 30 atomic % Fe it persists up to 775° C., and at 25 atomic % Fe only to about 675° C. A 2-phase region separates the 2 superlattices. EF (9)

Local Analysis and Micrography (Analyse Locale et Micrographie) P. COHEUR. *Rev. Universelle Mines*, Vol. 14, Sept. 1938, pp. 702-703. Descriptive review. Several examples show how a local spectrum analysis, made by directing a high-tension electric spark to a definite spot on a surface, can help materially to clear up doubts on composition or irregularities at the respective spot, which otherwise could not be obtained except by destructive methods. Crystallographic determinations can be made easily in this manner and be a valuable supplement to micrographic investigations. Ha (9)

Metal Crystals. An Examination of their Physical Characteristics. BRUCE CHALMERS. *Metal Ind., London,* Vol. 53, Sept. 9, 1938, pp. 243-246; Sept. 23, 1938, pp. 295-298; Sept. 30, 1938, pp. 323-325. Review. Of the 4 methods (condensation, freezing, electrolysis and recrystallization) of forming large metallic crystals, those of freezing molten metal and recrystallization have been used almost exclusively for experimental work. The orientation of a single crystal produced by careful annealing after straining is the same as that of the nucleus from which it grew, and shows a distinct preference for certain directions relative to the direction of application of stress; the orientation is not under control of the investigator. The possible residual effects of crystal boundaries and previous strain are not present in the solidification method. The orientation of the resulting crystal is approximately predictable from the direction of growth. 3 methods have been used for obtaining crystals of any desired orientation: (1) Cutting from large crystals in the required direction; (2) growing a single crystal in a glass tube provided with branches inclined at a variety of angles to the original direction of growth, and (3) the seeding method. The method of specifying structure by atom position is discussed in detail. Many, if not all, the properties of single crystals depend on the direction, in relation to the crystal axes, in which they are measured. Microscopic examination of the "pits" formed during etching gives some information on the crystal axes. This method is not easily susceptible to accurate measurement and has not been widely used. Another method is to observe the direction in which a beam of light is reflected by the surface of the etched specimen. A third method of determining the orientation without the use of X-rays consists in observing the surface markings that appear when single crystals are stretched. These markings are the intersections of definite crystallographic planes in which slip occurs. This method is destructive but can be used on wires that are too thin for optical reflection. The modulus of elasticity of single crystals depends on the direction of measurement, with a maximum value along one axis, and a minimum along another; the value of the polycrystalline metal lies somewhere between these 2 extremes. Measurements of this sort are difficult to make because most single crystals are soft. Plastic distortion of a single cylindrical crystal occurs as if it consisted of discs, each of which retains its shape, the discs sliding over each other. In metals having hexagonal structure, slip will take place only along the basal planes (001). The cubic metals are more complicated. In face-centered cubic metals, slip may occur on the (111) plane, while in the body-centered lattice, slip may be on the (110), (112) or (113) planes. In Sn with a tetragonal lattice, slip may occur on the (110), (100), (101) or the (121) planes. Furthermore slip will take place in these planes only in certain directions. Slip takes place in a given direction if the resolved shear force exceeds a value characteristic of the crystal. The normal component of that force has no effect on the force required to cause one plane to slide over another; the normal force exerts an influence in certain cases (Zn) where cleavage may occur instead of slip. Slip bands appear as: (1) A few widely spaced bands first, with subsequent slip taking place by new bands between them or (2) simultaneous formation of all the slip bands, with further slip taking place on the originally formed bands. Twinning cannot be described as either plastic or elastic distortion, because it is permanent and takes place suddenly, either under impact or when a sufficiently large force is applied. Twinned parts of the crystal must be regarded as having recrystallized into a new lattice as a result of displacement of the atoms from the original lattice by an applied force. In anisotropic materials, results obtained by experiments on polycrystalline samples depend on the distribution of orientation of crystallites in the specimen, and, therefore, on the previous treatment, mechanical and thermal, to which the specimen has been subjected. Measurement of directional properties in polycrystalline specimens give no indication of distribution of orientation. Investigations of optical properties of single crystals have little value in connection with fundamental properties of crystals. Magnetic properties show considerable variation with orientation. Available investigations on metallic diffusion in single crystals show that diffusion takes place more readily in some crystallographic directions than in others. The main problem that confronts those investigating metal crystals is to explain the mosaic structure, and the association of "glide" and work hardening. RWB (9)



X-ray Studies of Metals at Elevated Temperatures (Röntgenographische Untersuchungen von Metallen bei hohen Temperaturen) H. ESSER, W. EILENDER & K. BUNGARDT. *Arch. Eisenhüttenw.*, Vol. 12, Sept. 1938, pp. 157-161. Research. The change in lattice parameter with temperature of Pt, Au, Ag, Cu, Al, Ni, and Fe was determined. The magnetic changes in Ni and in Fe are stated to be accompanied by very slight inflections in the lattice parameter-temperature curves, but these are not shown clearly. The changes in the coefficients of thermal expansion with temperature were also determined dilatometrically, and the results by the 2 methods compared. SE (9)



METALLURGICAL MOUNTINGS

AB

SPECIMEN MOUNT PRESS

Pioneers a new technique for the metallurgist, and solves the problem of specimen mounting. It eliminates differential etching action frequently encountered with fusible alloys. The advantages of extreme edge studies, convenience in handling, speed and economy, contribute to the popularity of the new AB Specimen Mount Press.

ALL STEEL SECTIONAL AB SPECIMEN CABINET

provides convenient storage space for 600 specimens per 6-drawer section. Indexed spacers keep each specimen in its own compartment.

TRANSOPTIC MOUNTINGS

The dream of the metallurgist became true with our introduction of the transoptic mounting technique. For visibility of specimen from all sides, for ease in making electrical connections in electrolytic etching, Transoptic mountings are a definite step forward.

Polymorphic Transformation in Alloys of Iron with Arsenic and Antimony. V. N. Svechnikov & V. N. Gridnev. *Metallurg,* Vol. 13, Jan. 1938, pp. 13-19. In Russian. Original research. The Fe-As alloys had 0.05% C and up to 4% As, while the Fe-Sb alloys contained 0.11% C and up to 4% Sb. The starting and ending temperatures of the $\gamma \rightleftarrows \alpha$ transformation were determined during heating and cooling. The Fe-As and Fe-Sb alloys belong to the systems with a closed γ field. The parameters were determined; As and Sb increase the parameter of α phase and also form solid solutions by interstitial filling rather than by substitution. BZK (9a)

Effect of Low Cooling Rates on the Transformation Temperatures of Carbon Steels (Einfluss kleiner Abkühlungsgeschwindigkeiten auf die Umwandlungstemperaturen der Kohlenstoffstähle) F. Wever. *Naturwiss.,* Vol. 26, June 17, 1938, pp. 393-4. Review plus original research. Amount of undercooling of A_1 is only slightly affected by C content. With increasing cooling rates, the amount of undercooling rapidly increases to extraordinarily large values, i.e. with a cooling rate of only 0.01° C./sec., the equilibrium is shifted from 721° C. to 700° C. JZB (9a)

Influence of High Pressures on the Transformation of Carbon Steel. I. N. Efremov, Ya. P. Slesiskii & P. I. Georgievskii. *Metallurg,* Vol. 13, Jan. 1938, pp. 20-24. In Russian. Original research. The decomposition of austenite in 0.87% C steel was investigated while cooling under pressure at various speeds. The steel contained 0.23 Mn, 0.21 Si, 0.008 P, 0.01% S. Under pressures of 280,000-330,000 lbs./in.^{2} martensite and troosto-martensite structures were formed. The use of lower pressures produced other metastable structures (troostite and sorbite). BZK (9a)

Grain Size and Structure of Steel at High Temperature. I. T. Baruzdin. *Metallurg,* Vol. 13, May 1938, pp. 13-21. In Russian. Original research. The method consists of keeping the polished sample at 650°-1000° C. for 45 min. to 12 hrs. in a porcelain tube completely filled with dry dissociated NH_3 gas. Pressure in the tube is maintained at 30-90 mm. water even while the sample and the tube are being cooled. The austenite grains were visible on the whole sample surface, with the grain boundaries sharp and distinct. The time required for the test is ½ to ⅓ that for the McQuaid-Ehn test. BZK (9a)

The Iron-Iron Tungstide-Iron Titanide System (Das System Eisen-Eisenwolframid-Eisentitanid) R. Vogel & R. Ergang. *Arch Eisenhüttenw.,* Vol. 12, Sept. 1938, pp. 149-153. Research. The Fe-W-Ti system was studied thermally and microscopically in the composition ranges up to 50% W and 25% Ti, that is up to the sections Fe_2W_2-Fe_2Ti. These compounds form a continuous series of solid solutions. A ternary α solid solution of Fe_2W_2-Fe_2Ti separates out from the melt. The solid solubility line of this α constituent as well as the liquidus lines were determined. SE (9a)

Method of Determining Small Quantities of Residual Austenite in Steel. A. A. Kuznetsov. *Metallurg,* Vol. 13, May 1938, pp. 28-33. In Russian. Original research. A method is described for determining small amounts of residual austenite in quenched steel by the differential measurement of saturation. For steel containing 0.41% C, 0.34% Si, 0.47% Mn, 0.017% P, 1.31% Cr and 3.12% Ni, the amounts of residual austenite after quenching in air, water, and oil from 850°-1100° were 5.4-3.5, 1.7-4.2, and 3.9-5.3% respectively. For steel containing 0.22% C, 0.33% Si, 0.33% Mn, 0.013% P, 0.85% W, 1.30% Cr and 4.34% Ni, the amounts of residual austenite after quenching in air and oil from 850°-1050° were 4.3-5.7 and 2.1-0.9%, respectively. BZK (9a)

Investigation of Alloys of the Iron-nickel-sulphur System. G. G. Urazov & N. A. Filin. *Metallurg,* Vol. 13, Feb. 1938, pp. 3-17. In Russian. Original research. The liquidus surface of the ternary system consists of 3 primary fields: (1) Solid solutions of metals, (2) solid solution of Fe and Ni sulphides and (3) FeS. Investigation of the system FeS-Ni_3S_2, containing 42.5% Ni, showed that by decreasing the temperature below the eutectoid the concentration of the ternary solid solution decreases. Its decomposition results in the formation of free metals and the compound $2FeS.Ni_3S_2$. No ternary eutectic was observed. BZK (9a)

Possibility of Measuring the Internal Stress of Cast Iron by X-rays. Toshio Nishihara & Kohei Kozima. *Trans. Soc. Mech. Eng., Japan,* Vol. 4, May 1938, pp. 110-113. In Japanese. English abstract p. S-19. Original research. The same testing method previously used for the determination of internal stresses on the surface of a machine part made of pure Fe was applied to cast Fe. The inter-relation between internal stress induced by bending and lattice constant was experimentally established. A graphical presentation shows this inter-relation to be almost linear for cast Fe, although the accuracy of the results is not quite so good as with pure Fe. EF (9a)

The Diffusion of Hydrogen Through Nickel. C. B. Post (Carpenter Steel Co.) & W. R. Ham (Penn State) *J. Chem. Phys.,* Vol. 6, Oct. 1938, pp. 598-605. Original research. The diffusion of H through commercial and very pure anode Ni was determined from 1100° to 150° C. The diffusion rates vary in a perfectly regular manner throughout this region, except for a discontinuity at the Curie point. The Rydberg series found in Fe has not been found in Ni. A very exact agreement with the formula $R = AT^Z p^Y x^{-b/T}$ was found in all cases. After very long heat treatment with H, resulting in decarburization, the value of Y in the above equation for anode Ni becomes +0.5 with the possible exception of a region within 3° of the Curie point. The magnetic transition of Ni as shown by diffusion is abrupt, the isobars below the Curie region being as straight as those above. There is always a sudden drop in the value b, as calculated from the simple equation $R = A^{-b/T}$ at the Curie point, that value changing in the purest Ni from 6600 to 5800 with rising temperatures. No systematic breaks appear in the isobars at high temperatures, such as are found in pure Fe, but, nevertheless, the value of z indicates that the diffusion of H possesses appreciable energy within the lattice. The Curie region shows marked hysteresis and is similar to the Curie region of pure Fe in this respect. Existing theories of ferro-magnetism seem to require modification inasmuch as the Curie transition in Ni appears to take place about as abruptly as the body-centered face-centered transition in Fe. A variation in H concentration in Ni near the Curie point does not markedly affect the latter. The loss of ferro-magnetism at 360° C. is essentially an atomic phenomenon and should not be associated with conditions in aggregates of atoms or atomic domains. During the Curie transformation, for a finite time, there appears to be an additional electron in the valence shell of some Ni lattice points. A possible description of the change from the ferro-magnetic to the para-magnetic condition in the transition elements is that an electron is moved from the 3d shell to one of the 4-levels followed more or less quickly by the drop of another 4-level electron back to such a 3d shell as to result in pairing of electron spins in the 3d shell. EF (9b)

X-ray Studies on Cobalt-tin Alloys and a Comparison of the Systems Co-Sn, Fe-Sn and Ni-Sn (Röntgenuntersuchung von Kobalt-Zinnlegierungen und ein Vergleich des Systems Co-Sn, mit Fe-Sn und Ni-Sn) O. NIAL. *Z. anorg. allgem. Chem.*, Vol. 238, July 1, 1938, pp. 287-296. Experimental. α-cobalt dissolves only a very small amount of Sn. At 1000° C. β-Co dissolves up to 2.5 atomic % Sn. Four intermediate phases exist in the system: A phase γ′ having a NiAs type structure with dimensions between $a_0 = 4.096$, $c = 5.161$ A.U. and $a_0 = 4.116$, $c = 5.177$ A.U. that contains 41-42 atomic % Sn. In this type of Co-Sn lattice are excess Co atoms in random distribution. Below 550° C. these atoms become ordered and γ′ changes to a superstructure phase γ, the structure of which is probably hexagonal with dimensions $a = 16.356$, $c = 5.198$ A.U. The third phase is CoSn, which is hexagonal with $a = 5.268$, $c = 4.249$ A.U. and has the same structure as PtTl. Space group D_{6h}^1 — C6/ mmm. The fourth intermediate phase is $CoSn_2$, which is tetragonal with $a = 6.348$, $c = 5.441$ A.U. Space group D_{4h}^{18} — 14 mcm. A revised diagram of the Co-Sn system is given. Comparison of the systems Fe-Sn, Co-Sn, and Ni-Sn shows that they have in common only a phase of the NiAs type. CoSn has an analogue in FeSn, but otherwise the 3 systems are different. HFK (9b)

The Indium-lead System (Ueber das System Indium-Blei) S. VALENTINER & A. HABERSTROH. *Naturwiss.*, Vol. 26, Aug. 5, 1938, p. 517. Research. Earlier results indicated a continuous solid solution, which seemed improbable, since Pb is face-centered cubic, and In is tetragonal. In and In with a little Pb have a face-centered tetragonal structure with $c/a = 1.08$. At 10 atomic % Pb a face-centered tetragonal phase with $c/a = 0.94$ appears, which increases until it is the only constituent at 20 atomic % Pb. At 27 atomic % Pb, the Pb lattice first appears, with a lattice constant that is only 2% smaller than that of pure Pb. Above 35 atomic % Pb, only the Pb lattice can be detected. JZB (9b)

The Manganese-vanadium System (Einige Beobachtungen am System Mangan-Vanadium) H. CORNELIUS, W. BUNGARDT & E. SCHIEDT. *Metallwirtschaft*, Vol. 17, Sept. 16, 1938, pp. 977-980. Research. Mn-V alloys containing from 0 to 80% V were investigated, using thermal analysis, microscopic examination and X-ray diffraction studies. All alloys, especially those with more than 90% Mn, are very hard and brittle. Solidification temperature rises with increasing V content until at 60% V it is over 1770° C. The solid solubility of V in Mn is about 5% at high temperatures. 3 compounds were found, and the structures of 2 determined. GA (9b)

The Phases CoTe-CoTe$_2$ and NiTe-NiTe$_2$ (Ueber die Phasen CoTe-CoTe$_2$ und NiTe-NiTe$_2$) S. TENGNER. *Naturwiss.*, Vol. 26, July 1, 1938, p. 429. Research. Both groups of phases cover a large range of compositions, since CoTe (NiTe) gradually goes over into CoTe$_2$ (NiTe$_2$) with increasing Te. As the Te content increases, there is first a scarcity of atoms in the lattice, then irregular empty spaces, and finally the original lattice of the NiAs type becomes one of the CdI$_2$ type. The same phenomenon may be noticed in the Ti-H system: With small amounts of H_2, the H atoms are situated between the Ti atoms, then with increasing H_2, Ti_2H, TiH, and TiH_2 are formed without any 2-phase regions in between. JZB (9b)

The Structure of Cr-Mo Alloys (Ueber den Aufbau der Chrom-Molybdän Legierungen) W. TRZEBIATOWSKI & H. PLOSZEK. *Naturwiss.*, Vol. 26, July 15, 1938, p. 462. Research. The melting point of Cr is 1770° C. (determined on samples sintered in H_2 at 1200° C. and then resistance-melted in vacuum). Cr and Mo form a continuous solid solution with a minimum in the liquidus at 15 atomic % Mo and 1700° C. The lattice constant increases practically linearly with composition. These results do not agree with some thermoanalytical results, which indicated a eutectic at 1460° C. between Cr and a Mo-rich solid solution. JZB (9b)

The Iron-zinc System (Ueber das System Eisen-Zink) H. BABLIK, F. GOTZL & F. HALLA. *Z. Metallkunde*, Vol. 30, Aug. 1938, pp. 249-252. Experimental. X-ray and goniometer studies of a single crystal of the δ_1 phase, containing about 8% Fe, showed the unit cell to have the dimensions $a = 12.80$, $c = 57.6$ A.U. with a space group C_{6v}^4 or D_{6h}^4, and to contain 550 ± 8 atoms. The structure of $FeAl_3$ (*Z. Kristall.*, Vol. 88, 1934, p. 179) was also confirmed, with $a = 47.54$, $b = 15.485$, $c = 8.14$ A.U. GD (9b)

Relationship between Workability and Crystal Structure of Cubic and Hexagonal Lattices (Zusammenhänge zwischen Verarbeitbarkeit und Kristallstruktur von Kubischen und hexagonalen Werkstoffen) A. BURKHARDT. *Metallwirtschaft*, Vol. 17, Oct. 14, 1938, pp. 1083-1087. Descriptive. Compares the forming characteristics of Zn with Cu and Al. The effects of cold rolling, cold drawing, hot rolling and annealing are considered and related to characteristics of the lattices of the metals involved. GA (9b)

Cast Iron or Light Metal Casting (Grauguss oder Leichtmetallguss)? M. MAJER. *Giesserei,* Vol. 25, Aug. 26, 1938, pp. 424-427. Review. The factors to be considered in choosing between cast Fe and light metal castings are discussed; cast Fe is classified into 4 groups: Ordinary cast Fe (DIN 1691) with 2% Si, 0.7% Mn, 0.7% P, 0.1% S, tensile strength 23,000 lbs./in.², bending strength about 43,000 lbs./in.², Brinell hardness 120-160; cast Fe of better strength (DIN 1891), with 1.8-2% Si, 0.8% Mn, 0.5% P, 0.09% S, 26,000 lbs./in.² tensile strength, 51,000 lbs./in.² bending strength, hardness 150-180; special cast Fe (DIN 2691) with 1.6-1.8% Si, 0.8-1% Mn, 0.4% P, 0.08% S, 37,000 lbs./in.² tensile strength, 71,000 lbs./in.² bending strength, hardness 180-220; heat-resisting cast Fe with 2% Si, 1% Mn, 0.2% P, 0.08% Mn. These 4 groups are compared with 4 groups of light metals: Ordinary Al castings with up to 5% Cu, Zn, Si, and some Fe, Mn, tensile strength 17,000-24,000 lbs./in.², bending strength 50-80% higher, hardness 60-90; silumin castings with 11-13.5% Si, and remainder Al, tensile strength 24,000-31,000 lbs./in.², bending strength 50-80% higher, hardness 50-60; silumin-gamma with 11-13.5% Si, 0.4-0.6% Mn, 0.1-0.5% Mg, and remainder Al, tensile strength 36,000-43,000 lbs./in.², bending strength 50-80% higher, hardness 80-100; corrosion-resistant alloys, such as hydronalium or KSS, with 4-12% Mg, up to 1% Mn, 0.1-0.5% Si, and up to 1% Sb, 21000-28,000 lbs./in.², tensile strength, 50-80% higher bending strength, hardness 60-70. Material, weight, wear resistance and machinability all enter into the question of relative cost. Ha (10) — 3 — 4 — 5

German Development of New Brake Linings (Beitrag über eigene Arbeiten zur Entwicklung von Bremsbelägen aus deutschen Rohstoffen) RUDOLF OSWALD. *Deut. Motor Z.,* Vol. 15, Feb. 15, 1938, pp. 54-56. Original. The object of the author's experiments was to replace asbestos fibre in brake linings by metallic wool. Al and steel wool (0.03 mm. diam.) is embedded in resin or synthetic rubber. The new linings are wear-resistant, rigid, heat-conducting and not more sensitive to oil and grease than asbestos base linings. EF (10) — 6 — 7

The Effect of Boron on Nickel Steels. *Metallurgist (Suppl. Engineer),* Aug. 1938, pp. 146-148. Correlated abstract of 6 references. Improvement in properties of steel through boronizing or direct alloying is usually sought in the direction of increased hardness, but the surface layer produced by cementation with ferro-boron is claimed also to confer resistance to acid attack and to high-temperature oxidation. The increased hardness of B-containing steels is believed due to the presence of Fe_2B, which forms with up to 8.8% B; the compound is more soluble in α-iron than in γ. Fe-B alloys contain a brittle eutectic that may be harmful. The B-Fe-Mn diagram at 2% Mn is similar in many respects to the Fe-C diagram, and B alloys on quenching show Brinell hardnesses up to 400 and are softened by tempering. The austenitic Cr-Ni steels show a diminishing solubility for B with fall of temperature, and are therefore subject to precipitation hardening. Small amounts of B raise the Brinell hardness, yield point and tensile strength, and reduce elongation and impact values of normalized Ni steels. In quenched steels, B re-inforces the hardenability of the steels. Reheating the quenched alloys at 50° C. brings a marked increase in tensile strength; reheating at 150-250° C. lowers the tensile strength of B-Ni steels below the as-quenched value. VVK + FPP (10a) — 8 — 9

Cast High-chromium Manganese Steels. *Metallurgist (Suppl. Engineer)* Aug. 1938, pp. 158-160. Extended abstract of "The Influence of Manganese up to 20 per cent on the Structure and Properties of Cast Alloys with 30 per cent of Chromium." See *Metals and Alloys,* Vol. 9, Dec. 1938, p. MA 731 L/5. VVK (10a) — 10

Strong Trend Toward Use of Steel in Airplane Construction. *Steel,* Vol. 103, Sept. 5, 1938, pp. 15-17, 90. Survey. With the trend toward larger military and transport planes, stainless and heat-treated alloy steels are playing increasingly important parts. Some metallurgical engineers predict that stainless steel will soon be the most prominent metal in aircraft construction, and visualize the all-steel plane. Estimated requirements of stainless steel alone for a 4000- to 5000-plane year would be about 5000 tons, on the basis of present size. Steel comprises nearly 20% of the basic structural weight of a modern 21-passenger transport plane. The larger the plane, the greater the proportion of steel. Of the more than 2 dozen different kinds of steel used in present-day planes, most important in amount are the Cr-Mo and stainless steels. The former is used for highly stressed structural parts where welding is necessary and space is limited. The latter now are used primarily where corrosion resistance and heat resistance are the important factors. Ni steels are used for threaded parts. Among the latest developments are Ni-Cr-Mo steels, such as S.A.E. 4340 and 4345. Their excellent depth-hardening properties make them suitable for large sections. Steel castings are not widely used, but there are indications that their application may become more common. Ni alloys, particularly Inconel and K Monel, are receiving more recognition. Early disadvantages of Mg alloys have been overcome, but results of service tests in progress will decide how much will be used in the future. MS (10a)

X-ray Measurement of Stresses in Mild Steel after Exceeding the Yield Point in Bending (Roentgenographische Spannungsmessungen bei Überschreiten der Fliessgrenze an Biegestäben aus Flussstahl) F. BOLLENRATH & E. SCHIEDT. *Z. Ver deut. Ing.,* Vol. 82, Sept. 17, 1938, pp. 1094-1098. Research. The results of experiments, described in detail, indicate that in rods of various sections which were not stressed uniformly, partly below and partly beyond the flow limit, 3 ranges must be distinguished: (1) An elastic range of small dislocations, in which Hooke's law applies; (2) a transition zone in which the flow obeys the stress conditions, but where the dislocations are of the order of elastic deformations; and (3) a flow range where the flow conditions are valid for the stresses exerted, and the deformations can become very large. The flow limit under bending is no greater than under tensile stress and is independent of the section. The location of the neutral axis is not affected, irrespective of the bending moments causing stresses beyond the flow limit in some fibres. 9 references. Ha (10a)

The Nickel Cast Irons. A. B. EVEREST. *Foundry Trade J.,* Vol. 59, Oct. 6, 1938, pp. 253-254. Extended abstract. Review. Influence of Ni on cast Fe, types of Ni cast Fe, Ni in foundry, improvement of machinability, strength, hardness and wearing quality, heat resistance, magnetic properties, electrical properties and expansion properties are discussed. Ni is a graphitizer. It stabilizes the pearlitic matrix of the castings, and at the same time refines the structure and makes it more dense. Ni lowers the critical temperature so that progressive additions render the matrix of the Fe successively sorbitic, martensitic and, finally, austenitic. The austenitic cast irons are non-magnetic. The first Ni cast Fe developed in this connection was Nomag (Ni 12, Mn 6%). If Ni content is increased above that normally employed in this class of casting, the metal becomes magnetic again. The austenitic cast irons are of special value because of their high electrical resistance, this being 140 microhms/cm.³ AIK (10a)

Lightweight Development in Railroad Equipment Using High-tensile Steels. A. E. STUEBING. *Southern & Southwestern Railway Club Proc.,* Vol. 26, May 1938, pp. 8-28. Survey. The specific requirements of steel used in freight cars are explained, and the characteristics of the low alloy, high strength and Cu steels most commonly used are given in a table. The corrosion resistance must be high, especially as the plates are subjected at the same time to severe abrasion. Paint adheres better to the Cor-ten plates, for example, than to other materials, and cars made of this and similar steels give decidedly better service than standard steel cars. In corrosive atmospheres, Cor-ten has from 2-3 times the life of Cu steel. Ha (10a)

Do you know which one of the many types of Stainless Steel now available is BEST adapted to your particular service requirements?

Allegheny Ludlum offers *complete* service in all stainless alloys—chrome nickel or straight chromium types. Space does not permit listing every grade, but full information on the numerous modifications meeting the specific chemical and physical requirements of your processes is always readily available. This valuable data has been compiled over many years by our research and metallurgical departments, and is typical of the thorough cooperation offered by this organization. Technical bulletins describing these various types of Allegheny Stainless Steel will be sent upon request.

ALLEGHENY STAINLESS STEEL GRADES

CHROME NICKEL TYPES

Fifteen standard grades and many modifications are available . . . led in breadth of application by Allegheny Metal 18-8—used everywhere for its maximum resistance to corrosion and gleaming, permanent beauty of surface . . . and Allegheny Metal 25-12—widely employed as the most readily workable alloy combining high temperature resistance with high strength. Available to industry in all standard commercial forms and quantities.

STRAIGHT CHROMIUM TYPES

Nineteen Allegheny grades and several modifications afford assurance of finding the correct type for your purpose. Three of these grades, outstanding in general service to industry, are: Allegheny 46—for applications requiring combined strength at temperature, corrosion resistance and facility of fabrication; Allegheny 17—for resistance to chemical and atmospheric corrosion joined with facility of fabrication; Allegheny 28—for maximum temperature resistance, where fabrication demands are moderate.

OFHC

OXYGEN FREE HIGH CONDUCTIVITY

A Superior Copper

FOR ALL PURPOSES

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Light Alloys in Aircraft Construction. Recent Developments and Future Trends of Practice and Research. R. LE COEUVRE. *Metal Ind., London,* Vol. 53, Nov. 4, 1938, pp. 437-442. Presented before the Royal Aeronautical Society. Light alloys are being increasingly applied in aircraft construction, even in the face of constant improvement in heavy metals whose strength/weight ratio can at times exceed that of light alloys. *Recent Industrial Development:* In engines, Al alloys with 10% Cu were formerly used that developed 6½-7½ tons./in.², as-cast. Development of heat treatable alloys has increased this figure to 18½-21 tons/in.² Further development has made it possible to repair damaged crankcases by welding. Mg alloys have likewise been improved and good results have been obtained at temperatures up to 300° C. by additions of Ag and Ce. Equally important have been improvements in production methods, such as pressure die-casting for Mg and certain Al alloys for carburetor bodies, and press forging of pistons and other parts. Finer grain and generally improved characteristics are produced by subjecting parts to pressure, during solidification, in an autoclave. Aeronautical construction will tend more toward the use of sheet and strip for structural members. The method for assembling and mounting light metal parts can still be improved; replacement of the present cumbersome, stationary riveting machines by portable machines that will drill sheet and place and hammer the rivets will be an important improvement. Al-Mg alloys have superior salt water resistance and are easily weldable. Alloys of less than 7% Mg are heat treatable, amenable to deep drawing, may be worked hot or cold and easily welded. Their tensile strength is 20-23 tons/in.² with 25% elongation. Alloys of 7-9% Mg are somewhat stronger, may be worked cold or hot, but have a brittle range at 150°-350° C. Such alloys may be welded but the strength of the joint is inferior. Additions of Ti improve these alloys. Mg-base alloys are used as-cast for landing gears, wheels, supports, and various equipment while sheet is used for tank construction. The sheet material is easy to weld and develops 18-20.5 tons./in.² with 10-14% elongation. Owing to their corrodibility, however, Mg alloys must be protected, either by electrolytic or dichromate dip treatment, before painting. Welding offers a solution to the problem of producing water tight joints in seaplane hulls and floats, but does not overcome the danger of electrolysis. The use of less noble metals at points of contact has been suggested. Zn or Cd are suitable for this purpose, and may be conveniently applied by metal spray. *Trends of research:* Attempts to improve the mechanical properties while retaining the welding and stability properties are described. Difficulties with spot or seam welding of light alloys arise from the high electrical and thermal conductivities of the metal, relatively low fusion point, presence of oxides, and corrosion hazards caused by use of Cu electrodes and the necessity of changing the electrodes often. Excessive electrode pressure cold works the metal and will cause corrosion; if pressure is too low, pores and cracks are formed. Al-Mg alloys weld better than Dural. Industrially, heat treatment of Al-Mg alloy welds and stoving for protection could be simultaneously effected. Tests to produce watertight assemblies by seam welding have not given uniform satisfaction. Radiographic control of welds is an old, and when properly applied, very useful process. Research in automatically protected alloys, exposed to sea water, has been conducted for years. By addition to the Al base metal of suitably chosen constituents, the particles of which are finely divided, it is possible to obtain on the surface a continuous passive film. Invisible films, of a thickness less than the wavelength of visible light, are the most flexible, adherent and, consequently, the most protective. *Future industrial developments:* In the automotive field, the number of workers per unit per day has decreased from 110 in 1920 to 12 in 1936, through application of mass production methods. What has happened to the automobile can be extended to aircraft construction. In an average assembly, the working times are in the following ratio: Purely mechanical work 15%, semi-mechanical work 25%, assembly and mounting 60%. In an effort to reduce time of installation, the use of the following refinements might be applied: Exclusive use of weldable light alloys, power draw presses, electric welders, bend presses, welding machines, shears, band saws, planing machines, large heat treatment furnaces and large anodizing baths for treatment of assemblies. The use of the chignolle and the portable punch should be excluded. RWB + EF (10b)

Al and Its Alloys. F. A. FOX. *Machinery (London),* Vol. 52, Aug. 4, 1938, pp. 549-553; Sept. 1, 1938, pp. 673-676. Comprehensive review. Al alloys are used for (1) high electrical conductivity; (2) high thermal conductivity; (3) corrosion resistance; and (4) oxidation resistance. Solid solution type alloys are generally used for forging, while eutectic types are used for castings. Properties and composition of common English Al alloys are given. JZB (10b)

The Development of New Uses for Silver. A. J. DORNBLATT. *Mining Congr. J.*, Vol. 24, Oct. 1938, pp. 31-34. Major industrial uses are in electroplating and photography; largest engineering uses are in Ag-solders and brazing alloys. Ag alloys are also used in automobile and airplane engine bearings, electrical contacts, welding rods and electrodes, and in Ag-clad metals for chemical equipment. Studies are now being made of the possibility of using Ag salts as fungicides and insecticides. In the metallurgical field, promising results have been obtained by addition of Ag to Mg-base alloys, bronze and Fe. BHS (10b)

Stressed-skin Airplanes of Aluminum Alloy. B. M. FOSTER. *J. Inst. Engrs., Australia,* Vol. 10, July 1938, pp. 263-272. Descriptive. The chief characteristic of the "stressed-skin" type of construction is that the fairing is built of this metal or other material and is made to perform the dual function of load-carrying structure and aerodynamic fairing. Some of the types of construction and some of the methods used in solving the problem of design are described. WHB (10b)

Investigation of Bearing Bronzes for Rolling Mills. N. A. FILIN. *Metallurg,* Vol. 13, Jan. 1938, pp. 105-111. In Russian. Original research. Six bronzes were investigated with a view toward utilizing them as anti-friction alloys. Best results were obtained with the following alloys: (1) 57 Cu, 37.5 Zn, 1.5 Al, 2.5 Mn, 1.5% Pb. (2) 54.7 Cu, 38.4 Zn, 2.9 Mn, 4% Pb. (3) 87 Cu, 9.5 Al, 3.5% Pb. These are less expensive than Sn-bronzes and their microstructure shows that they may be used under friction conditions. BZK (10b)

10c. Effect of Temperature

H. C. CROSS, SECTION EDITOR

The abstracts in this section are prepared in cooperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Light Metals for High Temperature Service. *Light Metals,* Vol. 1, Sept. 1938, p. 283. Review. Of Mg alloys intended for use at high temperatures, a Mg-Ce-Co-Mn alloy is recommended. This material contains 10% Ce and 1.5% each of Co and Mn. A short time tensile test at room temperature shows 37,000 lbs./in.^{2} ultimate strength, while at 300° C. the strength is lowered to no less than 14,800 lbs./in.^{2} A table of 14 Mg alloys is shown giving short time tensile results from room temperature to 300° C. It seems possible that, with more suitable heat treatments, some of these values could be improved upon. The creep rate for a given alloy depends, in large measure, upon its prior heat treatment. As service applications of light metals are usually short, the total strain during a creep test of short duration is often a better design criterion than the results of a long time test. The curve of limiting creep stress against temperature lies below the proportional limit-temperature curve at 300° C. and higher. It has been observed that softening and change of microstructure may occur during a creep test without altering the creep rate. This is at variance with established results on Fe and steel where changes in structure are accompanied by changes in creep rate. There is definite need for information on effect of prior aging on creep of age-hardenable Al alloys. Unlike steels, non-ferrous alloys do not show a definite stress value which may be described as a "fatigue limit." Mg alloys have, however, a more definite fatigue limit than Al alloys. In the latter there is no definite correlation between tensile strength and fatigue resistance. Age hardening has only a very slight effect on the endurance limit. Considerable data are included on the endurance limit of Al alloys after various treatments and at different temperatures. The endurance limit at 3 different temperatures of Electron (composition and heat treatment not given) is as follows: 15° C.—9,400 lbs./in.^{2}; 150° C.—5,700 lbs./in.^{2}; and 250° C—2,280 lbs./in.^{2} The elastic modulus of Al alloys falls off rapidly with temperature. Tapsell has found the modulus of duralumin to be as low as 2,500,000 lbs. at 350° C., compared to 10,000,000 lbs. at room temperature. Other workers have found a considerably smaller falling off with temperature. Structural permanence under low stressing, coupled with resistance to oxidation are requirements which Al alloys in general easily meet. But certain applications, such as aero-engines, require extraordinary combinations of properties, and selection centers about permanence of properties, short-time tensile data at elevated temperatures, as well as creep resistance, and fatigue properties. More and more data are constantly required as the complexity of service application grows. In regard to developing light metals for temperatures in excess of about 250° C., Be-rich alloys are a possibility, or recourse may be had to duplex materials in which the part subject to the highest temperature may not be a light metal. See also *Metals and Alloys,* Vol. 9, Dec. 1938, p. MA 134 R 5. AUS (10c)

Giving

CHROME STEELS

greater

resistance

to heat

In certain industrial operations—such as oil refining—steel is subjected to a service involving an extraordinary combination of stress, high temperature and corrosion. Too severe for ordinary grades of plain carbon steel! Yet a 5% chromium addition to the steel more than paid for its cost, in terms of its unusual resistance to corrosion and to stress at high temperature.

The chief disadvantage of this type of steel, however, was a tendency to harden and become brittle—even when cooled at normal rates from temperatures encountered in welding or annealing. This was due to its chromium content.

As a solution to this problem, a Titanium-treatment for chrome steels was developed which has effectively overcome the air-hardening tendency. Due to its strong affinity for carbon, Titanium practically removes all carbon from combination with chromium (preventing the formation of martensite on cooling) and thereby keeping the steel soft under all conditions.

This problem is typical of the many on which TAMCO Engineers and TAMCO Research have offered helpful assistance. Perhaps you, too, can benefit through TAMCO co-operation. Write: The Titanium Alloy Manufacturing Co., Niagara Falls, N.Y. (Representatives in leading cities throughout the world.)

V. V. KENDALL, SECTION EDITOR

Corrosion Control—Studies and Operating Experiences. *J. Am. Water Works Assoc.*, Vol. 30, Aug. 1938, pp. 1342-1387. A series of brief papers as follows: **Engineering and Economic Aspects of Pipe Corrosion and Its Control.** THOMAS H. WIGGIN, pp. 1343-1352. Experiences recounted. Internal corrosion of pipes is very prevalent—almost universal—and the expense of good protection for metal pipes, such as cement-lining or tar enamel, is amply justified for metal pipes, while other less corrodible pipe, such as reinforced concrete or cement-asbestos, have also their place. Cleaning has its place, but one should be prepared for yearly re-cleaning if high coefficients are to be sustained. Lime treatment has proved of only limited value in the writer's experience in preserving flow coefficients. Degasification, as used by Powell and Burns, has been very successful in a closed system; how much exposure in open tanks will nullify its benefits remains to be demonstrated. **The Effectiveness of Chemical Treatment for the Control of Pipe Corrosion.** GEO. D. NORCUM, pp. 1353-1365. As the result of experiments which are still progressing, involving the routine inspection of pipe lines carrying water undergoing chemical treatment, the author offers the following generalizations: Corrosion can take place without the production of any red water and without any increase in the Fe content of the water in the distribution system. A coating can definitely be laid down in pipes by lime treatment. The coating spreads over the surface of old scale, but corrosion seems to be still going on within the tubercles. It could not be determined if the lime treatment was retarding the rate of tuberculation. Mains that have been mechanically cleaned corrode much more rapidly than those that have not been cleaned. **Calcium Carbonate Units and Corrosion Control.** I. M. GLACE. pp. 1375-1383. Excellent review with personal experience. **Correcting Corrosivity of Zeolite Softened Waters.** D. E. DAVIS, pp. 1375-1383. Data are reported from a number of communities on the use of the Langelier Saturation Index with zeolite softened waters. Ca and pH are the 2 factors exercising the greatest influence in affecting corrosion in zeolite treated waters. The ionic exchange of Ca for Na in zeolite softening tends to make the softened water more corrosive than the raw. This may be offset by increases in pH due to aeration (and loss of CO_2) or to direct absorption of H ions in the zeolite. **Experience with Zeolite Water Plant.** H. M. OLSON, p. 1384. The author's experience indicates that a zeolite system should be run undersaturated until scale in the piping system has been dissolved and then $CaCO_3$ correction made to protect the pipe. **Accomplishments with Chloramination.** J. WALTER ACKERMAN, p. 1385. Experience with Cl and ammonia treatment of 12 miles of 24 in. cast Fe pipe proved very satisfactory. **Use of Sodium Silicate in Corrosion Control at a Rayon Plant.** CARL ALEXANDER, pp. 1386-1387. Water should contain at least 50 to 60 p.p.m. silicates, calculated as silica, to form a protective film. At this plant, aluminum sulphate was used with lime and sodium carbonate as secondary treatment. Secondary treatment was replaced satisfactorily by sodium silicate. Sodium aluminate (which contained a certain percentage of silica) is now used. VVK (11)

Corrosion of Interior Parts of High-pressure Boiler Feed-pumps (Korrosion an Innenteilen bei Höchstdruck-Kesselspeise-pumpen) G. WEYLAND. *Wärme*, Vol. 61, May 21, 1938, pp. 379-382. Original research. Shows in some 10 illustrations corroded parts of high pressure boiler feed pumps. Pressure, operating time and general description of construction material are given without correlating these data with the corrosion observed; however no corrosion effects were noticed in pumps feeding water of a pH value of 8 and higher, while severe corrosion attacks took place at pH = 6.4 and 6.5 under comparable working conditions. Tests were made by using 4 different materials in a pump. After 1500 hrs. service, the runners made of cast electric furnace steel containing 1.5% Mn were corroded, therefore, corrosion resistant material must be employed for all pump parts if pH is lower than 7. EF (11)

A Study on the Electrode Potentials of Metals and Alloys in Nitric Acid Solution. YOICHI YAMAMOTO. *Sci. Papers Inst. Phys. Chem. Research, Tokyo*, Vol. 34, Sept. 1938, Abstract Suppl., pp. 34-35. English abstract. Original research. The single electrode potential of 21 pure metals, 2 non-metals (C and Si) and 6 alloys was determined in HNO_3 solutions of various concentration. A definite relation between the electrode potential determined 20 min. after immersion and the atomic number was established. No simple correlation between electrode potential and rate of attack was observed. The series of electrode potentials in fresh water and in HNO_3 solutions after 20 min. was as follows: (from lower to higher) *In fresh H_2O:* Mg → Zn → Mn → Cd → Pb → Fe → Si → Sn → high C-steel → Al → Sb → Ta → Co → Mo → Cr → 18/8 → 13% Cr stainless steel → 80/20 Ni-Cr → Ni → Bi → Monel metal → brass → Cu → Ag → W → Hg → C → Au → Pt. *In 5% HNO_3:* Mg → Mn → Zn → Cd → Pb → Al → Fe → Sn → Co → high C-steel → Ni → 13% Cr steel → Sb → 80/20 Ni-Cr → 18/8 → Bi → Monel metal → brass → Cu → W → Cr → Mo → Ta → Ag → Hg → Si → C → Au → Pt. *In 20% HNO_3:* Mg → Mn → Zn → Cd → Pb → Sn → Al → Fe → Ni → high C-steel → Co → 13% Cr steel → Bi → 80/20 Ni-Cr → 18/8 → Monel metal → brass → Cu → Sb → Ag → Mo → Ta → W → Hg → Au → Cr → Si → C → Pt. *In 40% HNO_3:* Mg → Mn → Cd → Zn → Sn → Pb → Ni → Al → Fe → high C-steel → Co → Bi → Monel metal → brass → Cu → Sb → Hg → 13% Cr steel → Ag → Mo → 80/20 Ni-Cr → 18/8 → W → Ta → Si → Cr → C → Au → Pt. *In 60% HNO_3:* Mg → Mn → Cd → Zn → Sn → Pb → Co → Bi → brass → Cu → Al → Sb → Ag → Hg → Monel metal → Ni → Mo → passive high C-steel → 80/20 Ni-Cr → 13% Cr steel → 18/8 → passive Fe → W → Ta → Cr → Si → C → Au → Pt. The experimental results are also given for 10%, 30% and 50% HNO_3 solutions. EF (11)

Influences of Many Factors on the Solubility of Copper-zinc Alloy in Acid. Part II. HARU KUGE. *Sci. Papers Inst. Phys. Chem. Research, Tokyo*, Vol. 34, Apr. 1938, pp. 434-446. In English. Original research. The solubility of Cu, 90/10, 80/20 and 70/30 Cu-Zn in 1 *N* HNO_3 was studied in relation to grain size. The test pieces were suspended at the end of an agitator, rotating at 320 r.p.m. The mechanical and thermal treatments applied to obtain different grain sizes are described fully and the results presented in microstructures. *Copper:* The larger the grain, the greater the solution rate. No difference was found between a grain size of 60 μ^2 and 93 μ^2. The next size studied was 500 μ^2. *90/10 brass:* 4 grain sizes falling between 50 μ^2 and 150 μ^2 were studied. Solubility increases almost rectilinearly with grain size. *80/20 brass:* Grain sizes of 33, 177 and 225 μ^2 were obtained by 3 different heat treatments. At 40° C., solubility increases proportionally to grain size but at 50° C., only a general trend in this direction was found. *70/30 brass:* 5 different grain sizes between 33 μ^2 and 280 μ^2 were studied at 50° C. Up to 200 μ^2, the larger the grain, the greater the solubility. Between 200 μ^2 and 300 μ^2 hardly any increase of solubility was found. A maximum point in solubility may occur owing to the presence of 2 opposite effects: The larger the grain, the greater the e.m.f. and, consequently, the solubility. But the greater the boundary area, which means the smaller the grain, the stronger the galvanic action between the impurities at the grain boundaries and the adjacent metal. (For Part I, see *Metals and Alloys*, Vol. 9, Aug. 1938, p. MA 515 L/1). EF (11)

Corrosion-resistant Steels for Ammonia Synthesis. A. V. SMIRNOV. *Zhur. Khim. Prom.*, Vol. 15, No. 2, 1938, pp. 30-38. In Russian. For parts operating at 500° C. and 750 atm., a Cr-Mo steel (0.2% C, 6.0% Cr, 0.5% Mo) is recommended. An alloy of the "Amfi" type (60% Ni, 9% Cr, 3% W, 2% Mn) is resistant to all corrosion and heat conditions encountered in ammonia synthesis. N_2 is described as being at least as important as H_2 in its influence on corrosion. NA (11)

THIS MODERN HIGH-SPEED, HIGH PRODUCTION MACHINE, REQUIRED GEARS OF . . .

AMPCO METAL

(Baker No. 3½—16 Three Way, Unit Type Way Driller and Tapper)

ONLY AMPCO METAL MET THE DEMANDS FOR SHOCK-PROOF, WEAR RESISTANT, AND SILENT OPERATING QUALITIES!

This remarkable Baker machine takes care of four operations, accurately and at high speed—drilling, reaming, chamfering, and tapping—on steering handle support arms. Gear trains must be built to "take it" and that's why Baker chose Ampco Metal for vital gears.

The driving heads are equipped with Ampco Metal gears running with heat-treated, SAE 2340 steel gears. This combination successfully meets all demands for shock-proof, wear resistant, and silent operating qualities.

Ampco Metal is the usual choice of machine tool builders for extreme service parts where long life is also demanded.

The Modern Method of Manufacturing Aluminum Powder. H. MEYERSBERG. *Aluminum & Non-Ferrous Rev.*, Vol. 3, Aug. 1938, pp. 299-302. Descriptive. The older process used Al lumps or Al foil as initial material. The lumps were produced by pouring Al on a water cooled fly-wheel; the foil had to be cut up. The powder was produced by stamping. The main disadvantage of this process is the danger of explosion during stamping and polishing operations. In the new process an inert gas, such as N, is used for protection. Flaky Al powder, required to have floating properties, should have an oxide film on the surface. Therefore, 1-3% O_2 is added to the protective gas; this percentage involves no explosion hazard. The modern way of disintegrating Al foil includes tearing up by hand, passing through magnetic separator and dissecting into small fragments in a saw box or similar machine. The final "flatting" is done in a drum that contains steel balls and a gear that lifts the balls up and drops them on the material during rotation. The number of balls usually used in ball mills does not yield the best results. The flake output increases with the number of balls, reaches a maximum, drops drastically, and reaches a second maximum 3 times as high as the first one. The amount of the steel balls corresponding to this second maximum of output is used for commercial production (patented in England). The drum itself is filled with the controlled atmosphere during the operation.

History of the Steel Industry in the Chicago District. G. C. KIMBALL (Carnegie-Illinois Steel Corp.) *Blast Furnace Steel Plant*, Vol. 26, Sept. 1938, pp. 919-920, 940-941. The Fe and steel industry was founded in Chicago in 1857 with the establishment of North Chicago Rolling Mill Co. Other pioneering plants were: Union Rolling Mill Co., founded in 1863, and Union Coal, Iron & Transportation Co. at Joliet. All 3 manufactured Fe rails. In 1865, North Chicago Rolling Mill produced the first steel rails rolled in U. S. These were rolled from Bessemer ingots produced at Wyandotte, Mich. Bessemer converter was installed at North Chicago Rolling Mill shortly thereafter. Union Rolling Mill Co. built 2 blast furnaces in 1868 and a Bessemer plant in 1871. Joliet Works began operations in July, 1870, and completed a Bessemer plant in 1873. Present South Chicago plant of Carnegie-Illinois Steel Corp. was started in the early 1880's with 4 blast furnaces, a Bessemer plant and a mill for rolling heavy rails. Construction of Gary Works began in 1906. Present annual capacity of district is over 15,000,000 gross tons of ingots.

Recent Developments in the American Iron and Steel Industry. CLYDE E. WILLIAMS (Battelle Mem. Inst.) *J. Iron Steel Inst.*, Advance Copy No. 16, Oct. 1938, 22 pp. Up-to-date review. The subjects reviewed include blast-furnace raw materials, blast-furnace operation, pig Fe, Fe and steel scrap, residual metals in scrap, open-hearth operation, Bessemer and free-machining steels, grain-size control, pit practice, mill practice, steel sheets and strip, metallic coatings, enamelling sheet, surface treatment and priming coats, sheet for atmospheric corrosion resistance, low-alloy high-strength steel, alloy steel for heat treatment, special-purpose steels and stainless steels. JLG (12)

The Sintering of Hard-metal Alloys. W. D. JONES. *Metallurgist (Suppl. Engineer)* Oct. 1938, pp. 171-175. Extended and critical review of paper by Meyer & Eilender in *Archiv. Eisenhüttenwesen*. See *Metals and Alloys*, Vol. 9, Oct. 1938, p. MA 625 R/6. VVK (12)

"TRENDS" . . .

a new department on page MA126, interprets today's news in the light of probable future developments. This will be a regular monthly feature. You will want to read it.

Developments in the Manufacture of Metal Powders. J. C. CHASTON. *Metal Treatment*, Vol. 4, Summer 1938, pp. 49-52. Review. Al paint powders are now being produced in special ball mills in which an impact action is produced either by the use of internal shelves (in the Hametag process) or by careful adjustment of mill speed and charge (in the Hall process). In the Hametag process, the material is removed from the mill and conveyed through the polishing machine by an inert gas that avoids danger of explosion. In the Hall process, milling is performed in a solution of stearic acid and Al stearate in light oil, and no subsequent polishing is necessary. Spherical shaped Pb powder for paints is made by attrition in a slow-running ball mill. Reference is made to the hydride process and some miscellaneous methods of making metal powders. 11 references. JCC (12)

Alloy Steel Designed for Specific Uses. VINCENT T. MALCOLM (Chapman Valve Co.) *Foundry*, Vol. 66, July 8, 1938, pp. 32, 33, 80, 83; Aug. 1938, pp. 28-29, 76, 78; Sept. 1938, pp. 30-31, 65-67. Practical. Divides special steels into those having high strength and toughness; those that resist wear, creep or elevated temperatures; those for welding; those that resist corrosion and oxidation; and free machining and non-seizing steels. Outlines briefly the functions of Cr, Ni, Mo, V, W, Ti, Co, Ni and Zr in various types of steels. Considers also variables met with and casting losses. Includes tables giving chemical composition of series of steels and their heat treatment. The 2nd instalment gives proper method of procedure to avert defects in castings. The final instalment describes the proper method of heat treating.
VSP (12)

Construction and Manufacture of Forged Iron Cannons for Firing Stone Balls in the Middle Ages (Aufbau und Herstellung der Schmiedeeisernen Steinbüchsen des Mittelalters) K. RITTER. *Tech. Mitt. Krupp, Tech. Ber.*, Vol. 6, Sept. 1938, pp. 113-127. A history of the cannons for firing big stone balls is given; they were built first in the middle of the 14th century and disappeared in the 16th. The Fe or steel used for them can be compared with a modern mild steel of 0.05% C, and had a tensile strength of 45,500 lbs./in.^{2}, elastic limit of 31,000 lbs./in.^{2} and an elongation of 35%. The manufacture in different countries is interestingly described. The cannon in some cases were capable of firing stone balls up to 200 lbs. An atlas of 11 tables illustrates technically interesting pieces. 13 references. Ha (12)

National and International Importance of Some Problems of German Metallurgy (Einige Aufgaben der deutschen Metallurgie, ihre nationale und internationale Bedeutung) E. HOUDREMONT. *Stahl u. Eisen*, Vol. 58, Nov. 3, 1938, pp. 1185-1199. General. Some of the metallurgical problems that Germany has attacked in furtherance of its 4-year plan, and to utilize low grade domestic raw materials wherever possible, are also of interest to other countries. Among these are: Smelting pig Fe with a more acid slag, and desulphurizing later with Na_2CO_3, thus making use of low Fe high SiO_2 ores; ore concentration; recovery of Mn and V; substitution of cheaper alloying elements and use of clad metals.
SE (12)

Scanning the Year's Progress in Metals, Their Treatment and Fabrication. *Steel*, Vol. 103, Oct. 10, 1938, pp. 126-128, 130, 137-138, 140, 143, 146, 148, 150-152, 154, 156, 158-159, 162, 164. Comprehensive review. Consists of a number of short articles, each written by an authority, on various phases of metallurgical development. Both ferrous and non-ferrous metals and alloys are discussed. MS (12)

Powder Metallurgy. G. J. COMSTOCK.. *Mech. Eng.*, Vol. 60, Nov. 1938, pp. 801-806. An account is given of the increasing importance to industry of the fabrication of objects from metal powders, and the development of methods of manufacturing metal powders is briefly described. Four principal commercial products are at present being made by powder metallurgy: (1) The refractory metals W, Mo and Ta, (2) electrical contact and electrode materials, (3) porous bearings, and (4) hard cemented carbides for tool and die materials. The manufacturing methods, equipment used for them and a variety of examples are described. 18 references. Ha (12)

books

Metal Coloring and Finishing

Hugo Krause

Chemical Publishing Co. of N. Y., New York, 1938. Cloth, 6¼ x 9¼ in., 222 pages. Price $5.00.

For some time there has been need for a comprehensive reference text in the field of chemical metal coloring and corrosion protection. This need was partially fulfilled with the advent of the new edition of Krause's book in 1937. Unfortunately it was in German and thus not available to many American and English readers. The present translation by an anonymous author, however, is a disappointment and in no way lives up to the original work. It is full of errors and appears to have been very carelessly done and proof read. For example, one glaring error which occurs repeatedly is the translation of *Salzsäure,* the German word for hydrochloric or muriatic acid, by *nitric acid.* The translator's apparent unfamiliarity with common terms of the art leads to the translation of the German verbs *beizen, dekapieren, brennen,* etc., all meaning to pickle a metal, by such obviously misfit, and even misleading, words as to *stain, to burn, to peel,* and even *to anneal.* The last mentioned gem occurs in a number of instances. Such well-known processes as the Bullard-Dunn electrolytic pickling process, correctly described in the original, are not so in the translation. Much of the descriptive matter is so confused in the translation as to be useless.

All of the book, of course, is not bad. Many sections are well translated. But in order to know which information is correct and which is not the reader would have to have a copy of the German edition at his elbow.—IVER IGELSRUD.

Handbook of Brinell, Rockwell and Vickers Hardness Testing *(Der Kugeldruckversuch nach Brinell, die Härteprüfung mit Vorlast und die Härteprüfung nach Vickers—ein Handbuch)*

Georg Reicherter

Julius Springer Verlag, Berlin, 1938. Paper, 6¼ x 9 in., 200 pages. Price RM 4.50.

This book isn't at all what its title makes it out to be. It is a combined catalog and instruction book for using a dozen types of hardness testers made by Reicherter. The usual precautions for obtaining accurate readings are given and the usual conversion tables appended.

It should obviously be given free to any purchaser of one of the machines listed and is equally obviously not worth its price on a hand book basis.—H. W. GILLETT.

Blast Furnace Practice

Ralph H. Sweetser

McGraw-Hill Book Co., New York, 1938. Cloth, 6½ x 9¼ in., 356 pages. Price $4.00.

Since the books of J. E. Johnson, Jr., were published, some twenty years ago, blast furnace design and operation has been written up only in articles on specific matters. Much work by Joseph and his associates has been published by the Bureau of Mines in scattered form. Only those intimately connected with the blast furnace, who have assimilated such publications as they came out, have a connected picture of the whole field.

Sweetser gives such a picture, as seen through the eyes of an experienced blast furnace superintendent, who strives to turn to account in actual practice, every new fact and new thought brought out by research, and whose practical experience lets him winnow the wheat from the chaff.

Everything a blast furnace superintendent might be concerned with gets more or less comment in the volume. The chapters cover the design, construction and repair of the furnace and auxiliary equipment, raw materials, theory and chemistry of the process, operating the process, by-products of the blast furnace, and the commercial, economic and accounting side. The writing is in a reminiscent vein throughout, with side comments culled from the author's own experience. Sweetser usually has pretty definite opinions on most moot points and doesn't hesitate to state them. The blast furnace man's jargon is freely used, usually with explanations of the terms. One peculiar phraseology is in referring to molten iron as it goes to the open-hearth in the hot metal process, as having "combined carbon."

The personal touch of Sweetser's style would carry conviction to any reader (even if he did not know Sweetser, as blast furnace men all do) that the author is writing from long experience. Few technical books are written as authoritatively as this; most authors deal with subjects so wide that much of the contents of their books are necessarily second-hand. Sweetser, on the contrary, has had close contact with everything discussed. Many quotations are given from others, but only because they express what he also believes on first-hand evidence.

Blast furnace men will not be able to get along without adding the book to their library, and metallurgical engineers in general will want it because it gives a readable, coherent picture of a branch of the industry whose literature has hitherto been scanty.—H. W. GILLETT.

Twenty-third Annual Review of the Silver Market

Handy & Harman, New York, 1938. Cloth, 5 x 7 in., 30 pages.

This volume is devoted chiefly to appraisal of the U. S. Government's silver-buying policy. It is estimated that this has cost over a billion dollars, 82% of which went to foreign producers, and has resulted in a decreased use of silver throughout the world. As a Bombay correspondent puts it: "India is slowly losing the fascination she has had for silver for centuries and is turning to other types of investment. With China in the hands of the Japanese, the U. S. Treasury will be the only admirer of silver."

The economics of the case indicate that so much damage is being done the country by the hand-out to silver producers that the ultimate repeal of the Silver Purchase Act of 1934 is considered probable.

Owing to general business shrinkage, total consumption of silver by arts and industries in the U. S. and Canada in 1938 showed a 13% drop from the previous year. Motion pictures and silver-plated ware each only used 5% less, jewelry and sterling silverware lost 15%. The dental trade also used less silver. Purely industrial use showed a 35% decline. Use of silver in electrical and chemical trades in England is on the increase. Basic conditions indicate a continued growth of industrial uses in the U. S.—H. W. GILLETT.

Forging Practice

C. G. Johnson

American Technical Society, Chicago, 1938. Cloth, 5¾ x 8½ in., 136 pages. Price $1.50.

The series of books of which this little volume is a typical unit represents an interesting and useful publishing innovation. Simple, elementary, authoritatively written, and inexpensive, each book is evidently intended for non-experts of various classes: Trade school and technical high school students, metallurgical engineering students in their early college years, and in general anyone in industry who needs to know how certain things are done, without necessarily having to do them.

We particularly recommend this and similar books to young men just out of college, and just starting out on a metallurgical career, whose academic training has probably ignored many of the practical points discussed by the author, a professor in mechanical engineering at Worcester Polytechnic Institute. Industry expects the metallurgical engineer to have a somewhat broader knowledge of his subject than he can get in the present-day courses in "metallurgy." He will be impelled not only to learn as early as possible what happens to the structure and properties of metals when they are worked, heated, cooled, joined, etc., but also to be familiar with the engineering equipment available for performing these operations. Books like this therefore fulfill a real need in making such information available in brief and generally accurate form.

The treatment is extremely practical and covers not only "forging" as it is ordinarily understood, but hot and cold rolling, roll piercing, cold swaging, pressing, drawing and spinning, and extrusion. Equipment, methods, metallurgical effects and auxiliary operations, such as heating and heat treatment, are discussed for each process.

Of course, as one would expect in any book of this size, the treatment cannot be very intensive, but it does cover adequately the general field of plastic working in useful, understandable fashion.—FRED P. PETERS.

The Mineral Industry During 1937

G. A. Roush

McGraw-Hill Book Co., Inc., New York, 1938. Cloth, 6½ x 9½ in., 778 pages. Price $12.00.

This volume appears each year and this one supplements the 45 previous issues. As in the past, it brings up-to-date statistical and general information on the industry in this and other countries. There is also included some general technological and trade information. In this volume there are 33 contributors who are generally recognized as authorities in their respective fields. Much of the principal minerals and metals are discussed and much valuable general information is offered. The sections on Foreign Coins, the State Geological Surveys, the Trade Associations of the United States, the Professional Organizations of the United States and Canada, the Current Tariff Rates on Mineral and Metal Products and Weight Conversion Factors will be referred to by many.

The introduction to this volume calls attention to the fact that the editor completes his 25th volume with this issue. Because of this he has thought, and rightly so, that the time is opportune to present a brief summary of developments during these 25 years. This is contained in a special section—"The Mineral Industry, 1913 to 1937." In it will be found considerable data and comments of interest.

A change in the method of indexing has been inaugurated and it is a good one. A detailed index of the contents of each section is placed at the beginning of each one so that the reader will have this more readily available for reference and guidance instead of being obliged to hunt through a general index.—EDWIN F. CONE.

Stephen Timoshenko—60th Anniversary Volume

Macmillan Co., New York, 1938. Cloth, 6¼ x 9½ in., 277 pages. Price $5.00.

This collection of 30 separate papers, by as many students or associates of Timoshenko, on the occasion of his 60th birthday, is a type of appreciation of a great teacher and scientist that is common abroad, rare in this country. The individual authors hail from Canada, England, Germany, Holland, Poland, Turkey, and the U. S.; Cambridge, California, Cal. Tech., Columbia, Harvard, M.I.T., Michigan, Oxford, Stanford, and Yale Universities; from the Goodyear-Zeppelin, Timken, and Westinghouse industrial organizations, and a few other scientific groups. Authors with strictly English names are much in the minority, and most of those are from England and Canada; the American authors, with a few exceptions, have foreign names. One wonders whether foreign training or ability inherited from foreign-trained ancestors, is required before an American has the proper background to grasp the type of mechanics which Timoshenko has been a pioneer in developing.

When a metallurgical engineer is forced to deal with problems in design that require difficult and special mechanics, he finds Timoshenko's books and articles not only sound and authoritative, but as clear and understandable as it is in the nature of such things to be. Some of his students and associates who wrote these 30 articles have learned something of his clarity, some might take a few more lessons.

The majority of the articles are straight mechanics that do not directly touch metallurgical engineering, but enough of them deal with questions of stress concentration, fatigue, wear and creep to make the volume of interest to metallurgists and engineers concerned with these problems. Articles in this class are by Ellis, on forgeability of copper, Horger on axle fatigue, Karelitz on dry friction, MacGregor on true stress in the tensile test, Nadai on mathematics of creep, Peterson on stress concentration in fatigue, Prandtl on plastic flow and elastic after-effect, Soderberg on creep, Taylor on plastic strain, Waters on relaxation and Weibel on photoelasticity. Most of the data and points of view of these authors have been previously published elsewhere, but space limitations have forced them to boil it down so that these articles are often more usable than the longer originals.

The volume is a deserved tribute and its contents have value. Its preparation was in the hands of a committee headed by Prof. J. M. Lessells, who also wrote the interesting introductory account of Timoshenko's career.—H. W. GILLETT.

German Grammar for Chemists and Other Science Students

John T. Fotos and John L. Bray

John Wiley & Sons, Inc., New York, 1938. Cloth, 5¾ x 8¼ in., 323 pages. Price $2.25.

This book was prepared primarily for the student of science and technology who is interested in acquiring a reading knowledge of German books and periodicals. With the increasing pressure of other subjects, students of chemistry and metallurgy cannot afford two or three years to obtain a reading knowledge of technical German, a necessity for the chemist, metallurgist or metallurgical engineer who wishes to keep in touch with developments.

Some years ago, the reviewer offered a course in Metallurgical German at the Carnegie Institute of Technology, and later at Columbia, without prerequisites. This book would have been very effective if available at that time.

The book will prove valuable to those who must acquire a reading knowledge of technical German, but will also prove of value to those who feel they already have acquired this reading knowledge.—RICHARD RIMBACH.

Revere's New Mill

Revere Copper & Brass Inc., has announced completion of a $3,250,000 brass and copper mill at Rome, N. Y., as part of a huge modernization program. In making the announcement, C. Donald Dallas, president, declared, "This new mill is the culmination of a plant improvement program started several years ago. In the past 5 yrs. several million dollars in addition to this has been expended in Revere plants at Rome, Chicago, Detroit, Baltimore and New Bedford, Mass." The Revere executive pointed out that much of the modernization program was carried out during a period of depressed business. "Heavy industry," he said, "cannot modernize during a period of great business activity. The idea that heavy industry must stop all capital outlay and accept plant depreciation and equipment obsolescence in dull times is all wrong."

Revere's new mill at Rome incorporates the latest innovations in straight-line production in the copper and brass industry. The mill has a monthly capacity of 2,000,000 lbs. of brass strip up to 20 in. in width and its compactness is indicated by the fact that this capacity is contained within a floor area of 72,000 sq. ft. which is believed to be the lowest ratio in the industry. Innovations include a new escalator conveyor system whereby the brass slabs are automatically fed and re-fed into the breakdown mill, each sequence being controlled by a series of electric eyes.

The new brass mill is adjacent to Revere's copper rolling mill in Rome, N. Y., built in 1929, and having a monthly capacity of 10,000,000 lbs. of sheets and strip up to 48 in. in width. This installation includes 4 stands of 4-high rolls operated in tandem and thus is claimed to be the largest continuous mill in the industry.

Electroplaters' 1939 Convention

The Newark Branch of the American Electro-Platers Society, which has been awarded the annual convention for 1939, is to make this convention the largest and best ever held by this society. The convention will be an international affair and will be held at Asbury Park, on June 19 to 22.

By making this convention an international one and also because it is only about an hour from New York City, twofold benefits will be derived. The location at Asbury Park will make it convenient to attend the New York World's Fair which many will want to visit.

N.C.E. Gives Metallurgy Course

The Newark College of Engineering announces a special evening course in physical metallurgy and heat treatment, which started Friday, Jan. 13, 1939. The course is given for men actively engaged in the metal industries (preferably with preparation in college physics and chemistry, or its equivalent), and consists of a series of lectures and laboratory work. Lectures cover the manufacture of iron and steel, a detailed discussion of binary and ternary alloys and the effect of alloying constituents on steel. Laboratory work includes the microscopic examination of 15 to 20 metals, carburizing practice, use of the dilatometer, calibration of a thermocouple, and an intensive study of the effect of thermal treatment on carbon steels and non-ferrous alloys.

The laboratory is equipped with polishing equipment, hand microscopes, and two metallographic outfits. The furnace equipment includes both gas and electric furnaces, some of which are automatically controlled as to temperature. Both millivoltmeter and potentiometer type pyrometers are available.

The course is scheduled for 6 hrs. a week for 15 weeks on Wednesday and Friday evenings, 6:30 to 9:30. For further information, readers may address the registrar, Newark College of Engineering, 367 High St., Newark, N. J.

Youngstown To Make Leaded Steels

Lead-bearing steel will be produced by the Youngstown Sheet & Tube Co., licensed under the Ledloy patents of the Inland Steel Co. The use of lead-bearing steel for all kinds of machining operations has spread with amazing rapidity, Ledloy sales records show. Conservative examples of the faster machining speeds permitted vary from 30 per cent to more than 100 per cent, with tool life increased from 200 to 300 per cent.

The addition of lead by the Inland process has no measurable effect upon the physical or heat treating qualities of steel in any analysis, except perhaps for slight grain refinement, it is stated. It is interesting to note that Ledloy is but 0.04 per cent heavier than standard steels. This would amount to the volume of 3 cu. in. per ton of steel. Recent tests also show that lead-bearing steels may be coated or plated by the dipping or electroplating process in the same way and with the same results as regular steel.

International Acetylene Association to Meet In Houston

The 39th Convention of the International Acetylene Association is to be held in Houston, Texas, on March 8 to 10, 1939. Headquarters will be at the Rice Hotel.

In announcing the unanimous decision of the officers and directors, the secretary of the association referred to the splendid convention of the association in Birmingham last year—the first in the South—also to the increasingly numerous requests and invitations that have been received by the association during recent years to visit the great Southwest.

An interesting technical program, covering the most important developments in the application of the oxy-acetylene process of welding and cutting is in preparation.

Erratum

In an article—A French Appraisal of Rimmed vs. Killed Steels—in our December, 1938, issue, there is an error in the caption of the illustration on page 348. The composition of the split ingot should read 0.20 per cent carbon and not 0.020 per cent.

Navy to X-ray Vital Parts of Fleet

The United States Navy has turned to one of science's newest and most powerful life-savers—X-rays—for use in the New York and Philadelphia Navy Yards.

Capable of detecting all-important defects in metals up to 3 in. thick, the new units are expected to pick out flaws not only invisible to the unaided eye, but indistinguishable in the finished radiographs to all but experts specially trained to "read" them. Once spotted, the defective areas will be automatically replaced, with a consequent probable saving of life and limb on the high seas. In the air the safety factor is even more vital.

The new Westinghouse unit is designed to prevent such accidents by inspecting vital members before ships leave the airports or the ways. An important feature of the new unit is that, although it weighs three-quarters of a ton, it can be loaded aboard ship and moved about easily on its balloon tires. It is approximately 3 ft. wide by 5 ft. long over all, with a 10-ft. tube-stand. Yet so delicately balanced are its counterweights that the tube-head can be manipulated with ease.

Research on Chilled Car Wheels

The Association of Manufacturers of Chilled Car Wheels has established a research project at Battelle Memorial Institute on chilled irons for use in car wheels, according to an announcement by F. H. Hardin, president of the association, and Clyde E. Williams, director of Battelle Memorial Institute. The work will comprise a critical study of the material in current use and of new compositions in the iron-carbon group of metals.

International Foundry Congress 1939

Planned by the Institute of British Foundrymen, under the auspices of the International Committee of Foundry Technical Associations, the next International Foundry Congress will be held in London from June 12 to 17, and will be followed by a tour of the principal foundry centres of Great Britain from June 18 to 24 and from June 25 to 30. The President of the Congress will be W. B. Lake, J. P., president of the Institute of British Foundrymen for 1939-40, and one of England's pioneers in the electric furnace steel foundry industry. A number of prominent industrialists and scientists have consented to give their patronage to the Congress, the secretary of which will be T. Makemson, secretary of the Institute of British Foundrymen.

Inland Lights a New Blast Furnace

Inland has just completed, and lighted, its fifth blast furnace. This is a new 1,000 ton per day furnace of the very latest type.

An interesting program and ceremony was carried out. It has been 12 yrs. since the last Inland furnace was built.

● James H. Critchett and Francis B. Morgan have been elected vice-presidents of Electro Metallurgical Co., a unit of Union Carbide and Carbon Corp., New York. Dr. Critchett has been in charge of research work, and Mr. Morgan has been works manager for this company.

● Dr. F. R. Morral, formerly a professor at Purdue University, has become associated with the Continental Steel Corp., Kokomo, Ind.

● John F. Baker, formerly with Surface Combustion Co., is now representing the Ajax Electric Co., Inc., in the Pittsburgh district.

Free Service Department

Replies to box numbers should be addressed care of METALS AND ALLOYS, *330 West 42nd Street, New York.*

POSITION WANTED: Welding technician, with ten years' experience in research, development and supervision in the field of Shielded Arc—(Hand and Automatic) Gas and Resistance Welding. Thoroughly trained in "Welding Metallurgy." Broad knowledge of metals and methods of welding and testing. Capable of supervising all features pertaining to code welding, including X-ray work. Age 34. Married. Box MA-118.

POSITION WANTED: Executive, sales promotion experience, engineering background, analyst, statistician, 14 years' experience large manufacturer welding supplies, played leading part in organizing field service personnel, age 46, married, steady worker. Box MA-119.

POSITION WANTED: New England Representative. Metallurgical engineer desires connection with supplier or manufacturer of chemicals, minerals, metals or equipment, who is interested in personal representation in this area to the industrial and jobbing trade. Box MA-120.

POSITION WANTED: Foundry Metallurgist, age 26, single, 2½ years' gray iron foundry metallurgist. Two years as chemical analyst, ferrous metals. Technical training with practical experience. Available immediately. Box MA-121.

A LARGE firm of manufacturers wishes to purchase a patented or proprietary article, involving the use of aluminium or magnesium castings in large quantities.

Please submit details to Box No. 6, c/o Metals and Alloys, 330 West 42nd St., New York, N. Y.

trends

by Edwin F. Cone, Editor

Banks and Research

Recently we had a questionnaire from the vice president of a large bank in the east asking "what important developments will assert themselves in your field as a result of research in the next three years?" The information was desired as the basis of a general article on "new things coming along in various industries to fan bankers' interest in research and develop research mindedness in their dealings with industry." This is a laudable undertaking. It indicates a trend in the right direction—a better understanding by financial interests of the soundness of investments in research laboratories and their achievements.

Controlled Atmospheres

We are impressed with the fact that, as we contact various individuals close to the situation, there is a strong tendency for controlled atmospheres, hitherto applied largely to the annealing and normalizing of sheet and strip, to be improved so as to be applicable to heating or quenching in heat treatment which will avoid pickling losses or the necessity of machining off a decarburized skin and the combination of controlled atmosphere heating with a skin gas carburizing action. Progress in the application of controlled atmospheres is rapid and our visits to various heat-treating departments bring out the fact that furnaces with such atmospheres are more and more being used.

Sponge Iron

Imports of sponge iron have expanded rapidly in recent years. In 1931 they were only 17½ gross tons per month but in 1936 and 1937 the average was between 156 and 162½ tons each month—all from Sweden. The 1938 volume has been less due to the "recession" in business. A considerable portion of this is used in powder metallurgy—largely for bearings—according to Gregory Comstock.

Bearings of Ag-Base Metal

Silver-base bearing metals are on the way. In some of the present-day large aircraft engines, the shortcomings of bearing materials have been realized. It is believed that the silver-base alloys will meet the more drastic requirements. This situation was discussed in an article in our December, 1938, issue by R. W. Dayton. Further elaboration will be available in a paper by the same authority before the mining engineers' convention this month.

Die Castings

We had the pleasure recently of hearing an instructive and comprehensive address by Charles Pack, vice president of the Doehler Die Casting Co., on "Die Castings." In reply to a question as to whether the heat treatable or age-hardening aluminum alloys are being die cast, he replied that they are being successfully made and used in the as-cast condition but are not being heat-treated. The present alloys do not lend themselves to such treatment, partly because of distortion. Mr. Pack believes that alloys of this character will be developed which can be die cast and heat treated.

German Electric Steel

That the trend in the production of electric steel in Germany is decidedly upward is revealed by a study of German statistics. For 1937, the latest official data, the electric and crucible (mostly electric) output was over 700,300 metric tons, an increase of 40.5 per cent over the 1936 total and by far the largest on record. This trend is particularly true since 1934. In comparison the same American production was 846,471 gross tons in 1937, an increase of only 9.5 per cent over 1936. In 1937 the German electric steel output was about 3.5 per cent of the country's total; the American was 2.37 per cent. If the present trend continues, Germany may surpass us in electric furnace steel.

Basic Open-Hearth Steel

A tendency in recent years which has gained momentum is the greater use of basic open-hearth steel. This grade is now being used for products which only a few years ago were considered poor in quality unless made of acid open-hearth. There have been marked improvements made in the processing and control of basic furnaces so that basic steel is regarded by many as good as acid. We know of one large plant which formerly made all of its steel in acid furnaces—at present most of these are basic and the product is of as high, if not higher, grade than ever.

More About Basic O.-H.

Statistical evidence of the trend to basic open-hearth steel is furnished by a study of data of the American Iron and Steel Institute. In 1917, of the total open-hearth steel ingot output, 95.73 per cent was basic; in 1923, this was 98.12 per cent. Four years later (1927) 98.67 per cent of the total was basic and 10 years later this proportion had increased to 99.27 per cent. In capacity calculations also, the data are similar. In 1917, basic open-hearth capacity was 93.96 per cent of total ingot. By 1937, or 20 years later, this had increased to 98.92 per cent. If this trend continues, the quantity of acid open-hearth ingot steel will soon have almost disappeared.

Foreign Ferromanganese

Because of competition from foreign producers of blast furnace ferromanganese, American makers were obliged in January to reduce their quotations from $92.50, seaboard, to $80 per gross ton of 80 per cent alloy. The principal sources of the foreign supply have been Holland, Czechoslovakia and Dalmatia. Some of this product has been made from "distress" supplies of manganese ore. This trend is pointed to as one result of the conditions in Germany from which country metal men have been forced into other fields of activity.

New Equipment and Materials

Manufacturers are invited to send to the Editor items which are suitable for this Department. Illustrations are acceptable, preferably in the form of cuts no more than 2 in. wide.

The FerroTemp Pyrometer

The Harry W. Dietert Co., Detroit, announces the "FerroTemp" which is a pyrometer unit for measuring accurately the temperature of molten grey and white iron by means of an immersion thermocouple. The thermocouple of the FerroTemp is 1⅛ in. outside diameter and 19 in. in length. The depth of immersing the thermocouple into the molten metal does not affect the accuracy of temperature readings. The life of the economically priced thermocouple is better than 100 immersions. Every thermocouple receives a stabilizing treatment insuring accuracy for life of the couple. The iron and slag will not adhere to the thermocouple. The FerroTemp comes to the maximum temperature 15 seconds after immersing the thermocouple in the molten metal.

The FerroTemp is available in two models. A portable type as illustrated and a stationary type, similar to the portable model with the exception that a flexible extension lead connects the FerroTemp to a wall type pyrometer with a large dial which may be read at a 50-ft. distance.

The FerroTemp of the portable model is equipped with a sturdy meter having non-breakable crystal covering the bold type temperature scale which is 6 in. in length. The temperature scale reads from 1600 to 3200 deg. F. The smallest temperature division on the scale is 20 deg. allowing easy estimation to 10 deg. at a glance. The weight of the portable model FerroTemp is 8 lbs. The overall length is 47 in.

The stationary model of the FerroTemp is designed to operate at a fixed location in the plant. It has the advantage of working in conjunction with a large pyrometer which records the temperatures.

Either model of FerroTempt unit is independent of the human error and may be used as a control instrument to measure the tempera-

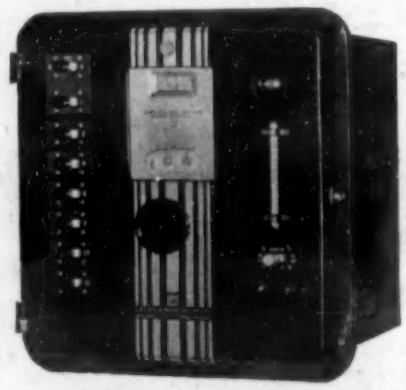
ture of the molten metal as it comes from the furnace or cupola. It may also be used to a great advantage to determine when a ladle of molten metal cools to a definite temperature as found most suitable for pouring a certain type of casting. For the intricately designed castings, practice has shown that, when the metal is poured at a temperature within 20 deg. of the ideal, defects are at a minimum.

A practice of measuring and recording molten iron temperatures from furnace or cupola every half hour has given information making it possible to adjust operating procedure to eliminate metal of undesirable temperatures.

Automatic Degreasing Machine

An automatic solvent degreasing machine designated as "Auto-Solv", has been placed on the market by the Mechanical Process Corp., South Orange, N. J. It is especially suited to cleaning small parts automatically. This is claimed to be made possible by a patented perforated scroll-type bucket.

The parts to be cleaned are deposited from the tote pan onto the loading table and, as the bucket passes a valve under the table, a measured quantity of material is dropped into it. The buckets are carried on a chain conveyor into the machine and through the lower tray of boiling hot solvent. Here they are rotated slowly in the liquid, gently separating the parts, and as a bucket leaves this bath, it passes through a shower of pure solvent and into another tray directly above the first. Again the bucket is rotated in this pure solvent where the parts are thoroughly rinsed. On leaving this tray, it is rotated slowly again where the excess solvent is drained and the parts are dried. When the container reaches the hopper, the bucket receives a rotation in the opposite direction, dumping the parts automatically into a waiting receptacle. An automatic control prevents mixing batches of parts.



The solvent used is D'Oilene "A" or D'Oilene "B", and provisions are made within the machine to constantly distill the dirty liquid and automatically separate the grease and oil from it, in order to provide a constant supply of pure solvent. The conveyor mechanism and its support are separate from the degreaser tank proper. Provisions are made for automatic control of the condensing water, steam supply, and overloading of the machine.

The outstanding features are the large capacity of the machine for the small floor area used, its simplicity of construction and operation, the economy of solvent and the low cost of the cleaning.

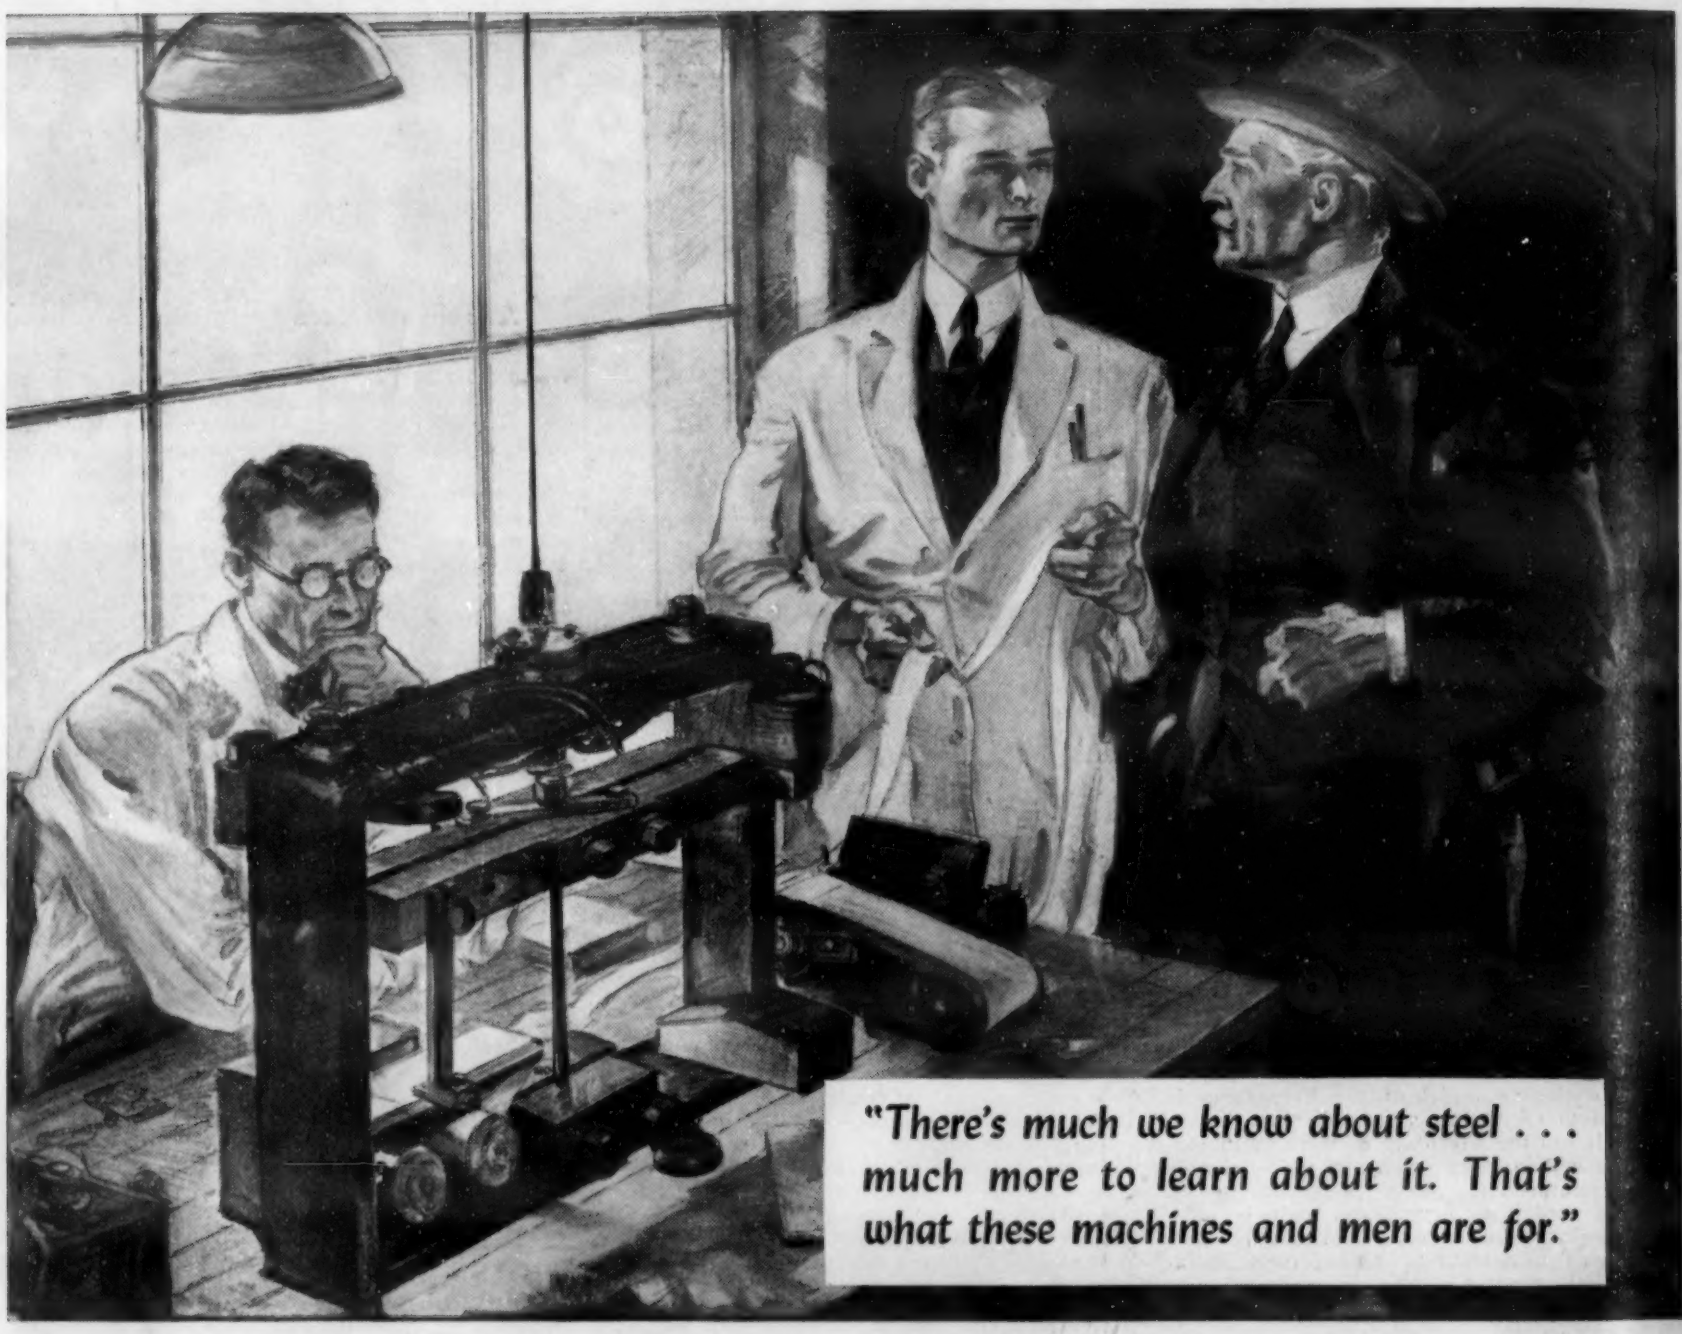
A Temperature Indicator

Ample space for toggle-type switches, for connecting any one of a number of couples to the measuring circuit, is provided in a new temperature indicator made by the Leeds & Northrup Co., 4934 Stenton Ave., Philadelphia. Installed wherever convenient, it enables an operator to measure temperatures of near or distant couples with equal reliability, by simply turning a knob, until a pointer comes to zero, and reading a temperature scale.

Use of a potentiometer measuring circuit, hand-standardized but with automatic reference-

junction compensation, eliminates uncertainties due to circuit-resistance variables. Scale is practically uniform and equally accurate throughout, and can be calibrated for single or double range, the latter for use with similar or different couples. Built-in terminals, check key and mercury thermometer can be included for checking with a portable indicator.

The rigid metal case mounts flush in panel, but can be equipped with hangers for surface mounting. The galvanometer is a sturdy replaceable unit. The only maintenance is occasional dry cell replacement. Warning that dry cell must be renewed is given when a red disc appears above the indicator scale.



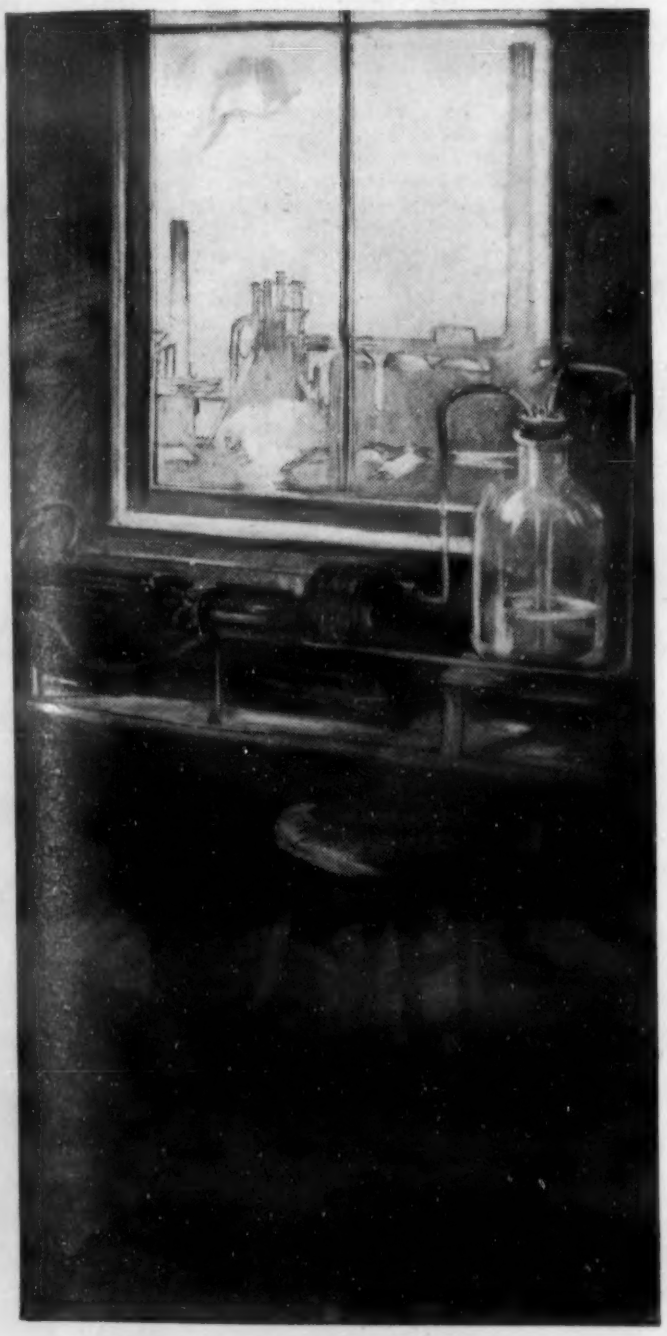
Separate selector switches can be used external to the indicator, if desired, or space for additional self-contained toggle-type switches may be obtained by assembling the indicator (with case removed) in a cabinet similar to that of the Micromax strip-chart recorder.

An Improved Sheet Mill

The Lewis Foundry & Machine Division of Blaw-Knox Co., Pittsburgh, announces a new improvement in its Lewis 3-high sheet mill. By streamlining of the mill tables, the rolling capacity of the mill is increased from a range of 1600 to 1800 pairs per 8-hr. turn to an output of 1700 to 2000 pairs.

(Continued on page MA 130)

STEEL YIELDS ITS SECRETS TO PRECISION INSTRUMENTS



And J & L metallurgists, reading and recording these revelations, find new facts that help improve and control the quality of steel.

"Steel is a stripling in age among the metals. There's much we know about steel—much more to learn about it. That's what these machines and men are for—to catch steel's secrets as they are revealed on indicator and chart. We collect

and classify this inner story into workable formulas for improving and controlling the quality of J & L Steel.

"This instrument, called a damping capacity tester, is one of the first of its kind to be used in this country. The innumerable graphs it has drawn for us contribute greatly to our knowledge of steel quality.

From a drawing by ORISON MacPHERSON

"Here in our new Pilot Plant is a complete steel works in miniature—the first of its kind—with 'pint size' steel furnaces, and little rolling mills. Here also is installed a physical testing laboratory as scientifically equipped for its purpose and as well staffed with technical men as that of a great university or research institute. It belongs to a steel company —an old and experienced steel company that looks to the future with youthful eyes. That's how J & L intends to maintain its position in the manufacture of controlled quality steels.

"Applied physics — underwritten and encouraged by Jones & Laughlin. Why? To make better steel, to supply customers like yourself with steel that works better and endures longer, that helps you to produce profitably finer finished products — articles of use and beauty for better everyday living here in America."

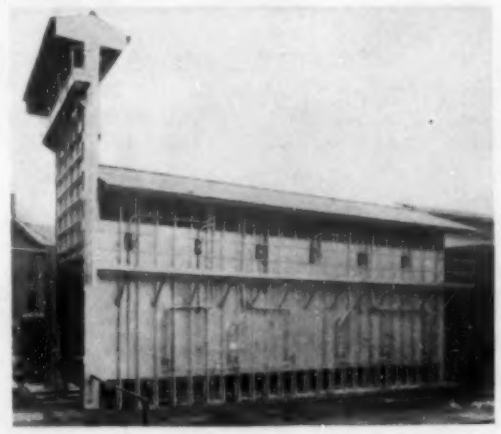
Triple Action Scrubber

The Peabody Engineering Corp., New York, announces the development of a new model scrubber for the removal of fog, dust and other particles from gas and air. It is a simplified, perfected adaptation of the scrubbing principles which characterize the company's various designs.

The new model will be known as the "Peabody Triple Action Scrubber," the separation of impurities being a three-step process. Gas enters tangentially near the base of the scrubber and is there relieved of coarse particles by cyclonic action. The gas passes upward through a zone of water or scrubbing liquid, supplied by slowly rotating sprays, operating at only 10 to 15 lbs. pressure. Dust particles mingle with water droplets at this stage. Continuing its travel, the gas encounters a plate with coarse perforations. On passing through these, the velocity of the gas is greatly increased and with it the velocity of the dust and water droplets.



The mixture of gas, dust and droplets is shot through the plate perforations directly at square impingement baffles, constantly wet, arranged so that the stream coming through each plate perforation strikes its individual baffle at maximum velocity. The dust particles and water droplets, on impact with the wetted baffle merge with the water surrounding the baffle. At this point, the real and final cleaning takes place. The dust particles hit the baffle with the directness of point blank rifle fire and, upon doing so, are effectively and permanently captured in the scrubbing liquid.

A liquid overflow pipe, located slightly above the level of the baffles, carries off the dust laden water, which leaves at the bottom of the scrubber shell. The gas or air, freed from impurities, is deflected around the baffles and continues upward toward the outlet of the shell. Eliminator vanes, located below the outlet, entrap any droplets of water carried upward in the gas stream, thus delivering dry gas.

Great efficiency is obtained in small sized scrubbing units. An interesting comparison is provided by a Peabody scrubber, 4 ft. in dia. and 6 ft. in height, doing the same cleaning job as a packed tower double the diameter and 130 ft. high. A new bulletin describing and illustrating the Peabody Triple Action Scrubber may be obtained by writing to the company.

Car Bottom Stress-Relieving Furnace

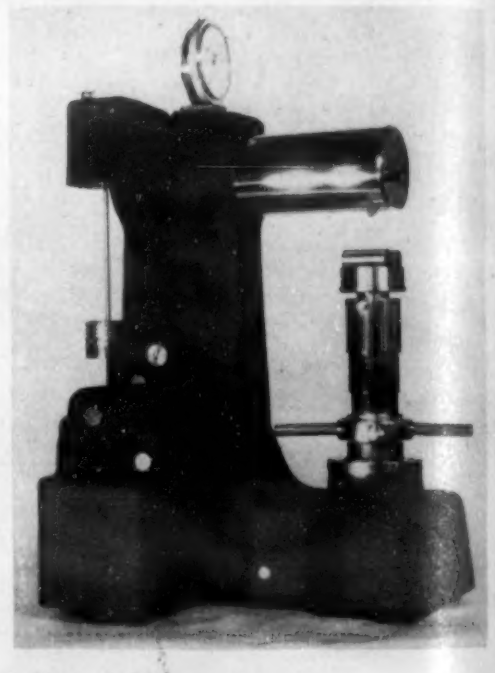
The American Car and Foundry Co., New York, has recently installed in its plant at Milton, Pa., complete equipment for the manufacture of fusion-welded tanks. To the Milton plant is allocated, exclusively, the building of

tank cars, and it has a capacity of 600 such cars per month.

This equipment includes one of the newest of car-bottom stress-relieving and annealing furnaces, designed and built by Morris Engineering Co., Philadelphia. The furnace is constructed of Babcock & Wilcox insulating firebrick. The open bottom is claimed to assure minimization of rail and car warpage. The inside dimensions are: 47½ ft. by 13 ft.; 17 ft. 3 in. high. The brick thicknesses are: Side wall and end wall, 13½ in. insulating firebrick; arch and door, 9 in. of the same material; car top 3 in. B & W insulating concrete is covered by 7½ in. insulating firebrick and paved with 4½ in. dense firebrick. A typical annealing cycle, including heating up to 1550 deg. F. and cooling, was 7¼ hr. for a tank weighing 33,000 lb., the oil consumption being 306 gal. Outside conditions were winter weather of December, 1938.

Inkless Recording Instruments—Indoor or Outdoor

Continuous accurate operation for 30 days without attention, at temperatures as low as minus 10 deg. F. and as high as 120 deg. F., is made possible by the new Type CF-1 line of inkless recording single- and double-range a-c ammeters and voltmeters announced by the General Electric Co., Schenectady, N. Y. The units are in the low-price range and are particularly well suited for voltage surveys, complaint investigations, and checking circuit load conditions. The inkless mechanism, which uses a typewriter ribbon, to make the record by a series of dots, results in greater simplicity, small size, and lightweight. There is no inkwell to clean, no pen to start, and nothing to freeze in cold weather. A cast aluminum alloy case of modernistic design protects the mechanism and further suits the new instruments for service while exposed to the weather. Although they are portable, the new instruments may be wall or pole-mounted.



Voltmeters are listed for the double range of 0-140/0-280 volts. Ammeters are for 0-5/0-10 amperes. Single range instruments can be supplied. The voltmeter is accurate to within 1½ per cent of full-scale value over the scale range normally used; that is, 110 to 130 and 220 to 260 volts, and to 3 per cent outside those limits. Ammeters are accurate to within 3 per cent of full-scale value. Type CF-1 recorders have a net weight of only 11 lbs. and are 10$\frac{9}{16}$ in. high by 8$\frac{9}{16}$ in wide by 5 31/32 in. deep. The chart is 4 in. wide (3½ in. record space) and is driven by a Telechron motor at 1, 2, or 3 in. per hr. A second Telechron motor operates the inkless mechanism.

The new line imposes an exceptionally low burden on instrument transformers—only 1 volt-ampere for the 5-amp. ammeter or the 140-volt voltmeter at 60 cycles.

New Rockwell Models

The Wilson Mechanical Instrument Co., Inc., 383 Concord Ave., New York, offers a new Rockwell model, furnished either as a "Model 3-CR Rockwell Hardness Tester" or as a "Model 3-CS Rockwell Superficial Hardness Tester" designed for the purpose of internal testing of large tubes and cylinders. The cylindrical tube being tested is simply projected over the horizontal testing arm. These machines can also be used for testing outer surfaces. These models are made in an 8 in. vertical capacity, 6 in. horizontal reach and will test internal surfaces down to 4 in. I.D.

The same sensitivity and accuracy are built into these special models as in the regular line and they have the same durable precision and rugged construction. Correct application of both minor and major loads is insured through the patented, frictionless, free-floating plunger system and mathematically correct loads and leverages. The operation is semi-automatic through motor operation. Standard readings are obtained on these machines. One of the most interesting applications, in several plants, is in the testing of airplane engine cylinders having nitrided surfaces.

A Metal Cleaner

A new metal cleaner that instantly removes stains and oxides from copper, brass, bronze and other metals, except aluminum, iron and zinc has been announced by Rapid Electroplating Process, Inc., 1414 S. Wabash Ave., Chicago. It is marketed as "1-Second Metal Cleaner" and is reported to contain no abrasives. It cleans by chemical action only and requires no rubbing. It has a jelly-like consistency and is applied with a brush and immediately wiped off with wet rag and then dried.

The substance contains no free acid or caustic and will not etch or harm the metal in any way even if permitted to dry on the surface. It retards the re-forming of oxide and because it contains no abrasive, makes it useful for rendering working surfaces chemically clean without leaving any gritty residue. It also cleans crevices inaccessible to some cleaners and leaves no powdery deposit.

Ordinarily copper, brass and bronze must be regularly and laboriously polished, each operation leaving a powdery deposit in crevices and on surrounding areas. It is claimed that by use of 1-Second Metal Cleaner, deposits are removed and polishing need only be done very occasionally when surface becomes badly scratched or abraded. *(Continued on page MA 131)*

The "Alnor" Multi-Point Pyrometer

This "Alnor Rectangular Type Pyrometer" was designed by the Illinois Testing Laboratories, Inc., 420 N. La Salle St., Chicago, to provide a rugged moderately priced instrument with multi-point switch, arranged for either back or bottom conduit connection and which would be fully water-proof, fume-proof and dust tight.

This pyrometer has proven to be exceedingly popular, not only with Diesel engine manufacturers, users, and engineers, for checking exhaust temperature, but it is also being used extensively for many industrial applications, which require close accuracy yet where a moderately priced multi-point pyrometer is desired.

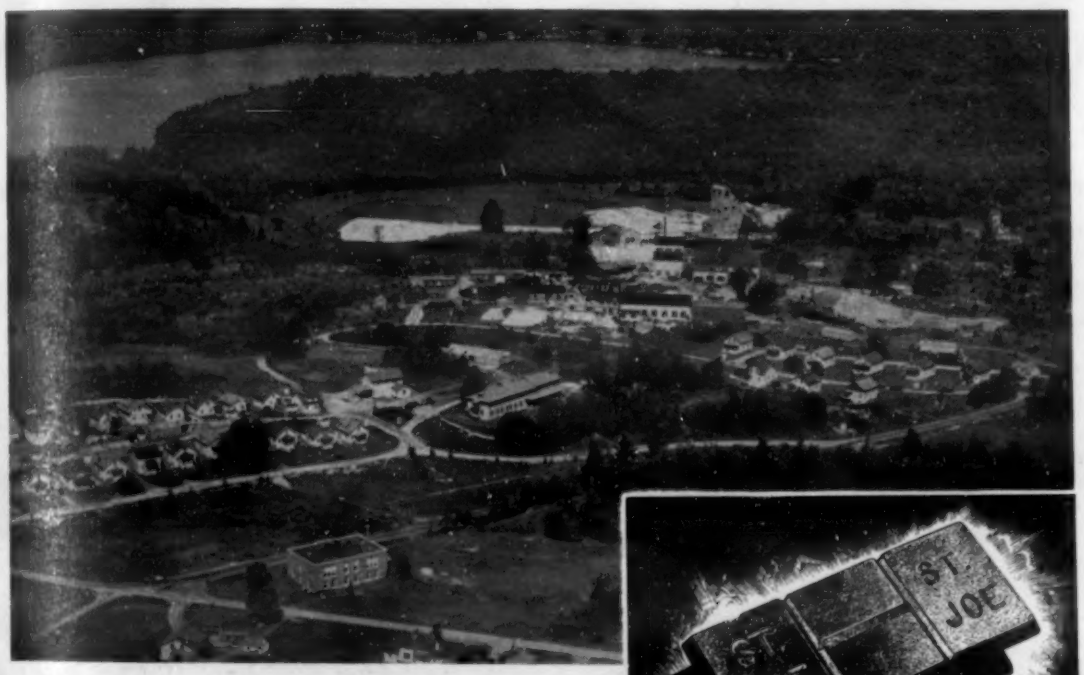
The movement of this pyrometer is ruggedly built and will withstand considerable vibration. However, where the instrument must stand severe jars and shocks such as when mounted on Diesel locomotives, shovels and excavators, a special shock resisting movement should be used. This will be furnished when specified at a nominal additional charge.

High accuracy is assured due to the simple, sturdy design, high torque, high quality of materials and workmanship. It has a scale 5 in. long with legible figures and sub-divisions. This with the broad spade pointer and fine needle provides quick accurate readings. The internal resistance is exceptionally high for this type of pyrometer. This assures greater freedom from errors caused by varying lengths of connecting wires.

The Flexi-Speed Carburizer

For some time the Timken-Detroit Axle Co., Detroit, and some other companies have been experimenting with a variety of unit or single containers for carburizing, in shape close to the contour of the object to be treated, mounting them on pusher trays of the usual type carburizing furnace. Despite the fact that this equipment (the unit container) greatly reduced the heating time, the warpage and improved the quality, the furnace capacity was also reduced because the area required was three times greater than that required for the larger carburizing boxes.

The experiments at Timken proved the advantages of the individual containers but the mechanics of moving these containers remained



unsolved for some time or until the General Alloys Co., Boston, introduced the "Flexi-Speed Carburizer." This is a special conveyor for moving the "stream-lined" containers through a furnace, as illustrated.

Some of the advantages claimed are as follows: (1) Permits absolute control of case depths with no experimenting—exactly predictable and repeatable results. (2) Handles mixed work of different case depth simultaneously, for example, a 0.030, 0.060 and 0.080 case may be run at the same time on different time cycles. (3) Is self-emptying. No costly waste and delays on each shut-down or change in cycle. (4) Can be run at any desired percentage of furnace production capacity. (5) Uses 80 per cent less compound per pound of work treated. (6) Employs minimum alloy weight per pound of work treated. (7) Eliminates "ram-rod" effect of pusher furnaces on alloy. (8) Low unit replacement cost. (9) Requires minimum size of furnace and floor area. (10) Offers a safe middle ground between box and gas carburizing.

FROM ORE TO METAL

The Story of St. Joe Electro-Thermic Zinc—Number 1 of a Series

THE BALMAT MINE

The mine, mill and town of Balmat, New York, developed and built by the St. Joseph Lead Company during the last ten years.

CLOSE TO THE BEAUTIFUL FOOTHILLS of the Adirondack Mountains, hidden for untold centuries under forest and lake, lay the great zinc deposit now known as the Balmat Mine.

Developed in 1927 and 1928 by the St. Joseph Lead Company, this great ore body which on the surface was a thinly mineralized non-commercial limestone, is currently shipping, with the old "Edwards mine" ten miles away, 60,000 tons of zinc concentrates, and 70,000 tons of iron pyrites per year.

One of the greatest zinc deposits in the United States, its large ore reserves are available for the smelter and refinery of the St. Joseph Lead Company at Josephtown, Pennsylvania, where the new St. Joe electro-thermic grades of zinc are produced.

A Cleaner, More Workable Clay

The Porcelain Enamel & Mfg. Co., Baltimore, Md., recently made the important announcement that it was about to introduce to the porcelain enameling industry a superior clay which had been refined by a new and revolutionary process. The material will be known as "Micronized Clay." A micronized product is one that has been broken down to a grain size ranging from one to 10 microns by the Micronizer reduction process. For purposes of comparison, the opening in a 200-mesh screen is 74 times larger than a micron. The material by this method is caused to grind itself rather than through contact with some other surface.

The refining of clay by the Micronizer process is claimed to insure a cleaner product; to increase efficiency through increased fineness; to be easier to handle; to reduce clay content; to have greater workability; to improve suspension; to have more rapid drain, and greater wetability; smoother set; and to reduce pitting and scumming to a minimum. All in all, Pemco Micronized Clay produces a finished product which is more durable and has closer texture.

(Continued on page MA 132)

Welding Helmets and Hand Shields

Four new welding helmets and four new hand shields have just been announced by the American Optical Co., Southbridge, Mass. These helmets and hand shields are made of the best grade vulcanized fibre, in either fabricated or one-piece construction, and are designed for comfort, safety, convenience and durability.

The helmets have a new free-floating headgear and an outside friction joint as standard equipment. Three types of glass holders are available: "Deep-Drawn Leakproof Steel," "Improved Bakelite," and the new "Dowmetal Lift Front," all of which assure maximum protection for welding plates and cover glass. An exclusive feature will be noted in these holders: They hold the welding and cover glass in position flexibly, not rigidly, in order to cushion the shock if accidentally struck. Glass can be easily changed without smudging or risk of breaking.

The hand shields are compact, lightweight, and well-balanced. Corrugated fibre handle, of new design, is deeply grooved to insure a firm, positive grip.

DU PONT CYANIDES & SALTS

for your

LIQUID BATHS

NO MATTER what your heat treating requirement, Du Pont offers a complete line of efficient, economical Heat Treating Salts for every purpose . . . shallow or deep case hardening, reheating, nitriding, coloring, tempering or drawing. Our Technical Service Staff will gladly cooperate with you in the selection and use of the proper Du Pont Heat Treating Cyanides and Salts to meet your individual needs. Contact our nearest office.

Wheelco Photo-Head

The Wheelco Instruments Co., 1933 S. Halsted St., Chicago, has just introduced the "Photo-Head" (photo-electric receiver), an adjunct to the Wheelco Flame-Otrol safeguard. It is designed for fuels other than gas, burning with luminous flames. The Photo-Head takes the place of the standard electrode, using the same Flame-otrol and affording the same instantaneous protection against flame failure. It provides safe, supervised, automatic ignition of oil burners, making the application of automatic on-off control possible with intermittent or constant pilots.

The Wheelco Photo-Head is designed to act instantly upon flame failure in furnaces, boilers, ovens and heaters. It is sensitive to the characteristics of a luminous flame, but not responsive to heat radiation from combustion chamber. In conjunction with the Flame-otrol, it shuts down the fuel supply with lightning speed, preventing entry of unburned fuel into combustion unit and eliminates this source of explosion hazard.

In cases where combustion equipment uses combination fuels, such as pulverized coal and gas, oil and gas or pulverized coal, oil and gas, the Photo-Head is used in conjunction with the standard electrode. Bulletin A-1105 gives complete detailed description.

"Kennametal" Tools

The McKenna Metals Co., 158 Lloyd Ave., Latrobe, Pa., manufacturers of "Kennametal" tools and blanks for steel and metal cutting, has issued a new 24-page catalog which is now available to all plant operating and purchasing officials. Kennametal is manufactured in three grades—hard, medium and soft alloys, and designated as KH, KM and KS, depending on the metals to be cut. Grade KH is the most generally applied grade where only one kind of hard carbide is used, as it machines not only steel, but non-ferrous alloys, and malleable iron as well as taking interrupted cuts on cast iron.

The basic ingredient of the steel-cutting grades of Kennametal, a synthetic tungsten titanium carbide composition, is the new substance corresponding to the chemical formula $WTiC_2$ which was developed by Philip M. McKenna. The main use of this compound at present is as an ingredient in the manufacture of hard carbide alloys in the form of blanks for tool tips, drawing dies, lathe centers, gage parts, rings, balls, rolls and other shapes, all harder than any tool steel.

MARCH, 1939

1. Ore Concentration

Crushing, Grinding, Plant Handling, Gravity, Concentration, Flotation, Magnetic Separation, Amalgamation, Cyanidation and Leaching.

2. Reduction

Blast Furnace Practice, Smelting and Electro-refining.—Ferrous (2a), Non-Ferrous (2b).

3. Melting, Refining and Casting

Open-Hearth, Bessemer, Arc, Induction, etc. Melting Practice and Furnaces. Foundry Practice, Equipment and Materials. Die Casting.—Ferrous (3a), Non-Ferrous (3b).

4. Working

Forging, Rolling, Drawing, Extruding, Punching, Stamping, Shearing and Machining.—Ferrous (4a), Non-Ferrous (4b).

5. Heat Treatment and Heating

Aging, Annealing, Carburizing, Hardening, Malleableizing, Nitriding, Normalizing, Surface-Hardening and Tempering. Furnaces, Soaking Pits, Refractories, Atmospheres, Fuels and Auxiliaries.—Ferrous (5a), Non-Ferrous (5b).

6. Welding and Cutting

Including Brazing, Hardfacing, Riveting and Soldering.—Ferrous (6a), Non-Ferrous (6b).

7. Finishing

Pickling, Cleaning, Sandblasting and Polishing. Electroplating, Metallizing, Galvanizing and Tinning. Coloring, "Oxidizing" and Non-Metallic Finishing.—Electrolytic Methods (7a), Non-Electrolytic Methods (7b).

8. Testing and Control

Methods and Equipment. Physical and Mechanical Property Testing. X-Ray and Magnetic Inspection. Spectrographic Analysis.—Fatigue Testing (8a).

9. Metallography

Structure and Constitution. Metallographic Equipment.—Ferrous (9a), Non-Ferrous (9b).

10. Properties and Applications

Including Relation of Properties to Engineering or Product Design.—Ferrous (10a), Non-Ferrous (10b), Effect of Temperature (10c).

11. Corrosion and Wear

Chemical and Atmospheric Corrosion and Oxidation. Abrasion, Cavitation and Erosion.

12. General

General Metallurgical Engineering, Powder Metallurgy, Economics, History, etc.

2·REDUCTION

Blast Furnace Practice, Smelting and Electro-refining.

Fixation of Sulphur from Smelter Smoke. Partial Pressures of Sulphur Dioxide Over Solutions of Sulphur Dioxide in Mixtures of Water and Various Aliphatic Amines. A. H. ROBERSON & G. W. MARKS. *U. S. Bur. Mines Rept. of Investigations* 3415, Oct. 1938, 45 pp. Research. All amines used were of commercial grade. Partial pressures of H_2O and SO_2 at 33, 50, 75 and 90° C. and 50, 60, 75 and 90% saturation of the following solutions are presented tabularly: Diethylene triamine (9.75, 18.01, 26.72 and 35.82%), triethylene tetramine (8.15, 16.13 and 25.41%), and monoethanol amine (no 50% saturation data) (11.53, 23.20, 34.69 and 46.81%). Limited data for the following solutions are presented: 21.65% ethylene diamine, 35.74% diethamol amine and 35.64% triethanol amine. These data indicated inferiority to the first group for the purpose in hand, and complete information was not obtained. Curves of relative viscosities of the 4 strengths of diethylene triamine solutions before and after saturation with SO_2 at 20-70° show gradual increase with increasing amine concentration before SO_2 saturation and enormous increases after. Densities of all solutions at 0, 25, 50, 60, 75, 90 and 100% SO_2 saturation, 25-85°, are shown tabularly. Volume changes from 0 to 100% saturation give J shaped curves, negative from 0 to about 90%, then rising very abruptly. The higher the amine concentration, the lower the curve drops, the quicker the break occurs and the higher the curve rises. Curves on SO_2 removal are presented. Boiling at 98-101° is more effective than heating at 91-93°. SO_2 removal decreases with increase in concentration, but not markedly above 60 mg. of amino N per cc. Extensive tables are presented showing concentration of H_2O, amine and SO_2 in all solutions and at all temperatures used in the partial pressure studies. The effective capacity of various solutions in g. SO_2/l. are 1:1 xylidine, 207; 9.82 g. $Al_2(SO_4)_2$/100 ml. solution, 74; ammonium sulfite-bisulfite—22.5 moles NH_3/100 moles H_2O, 171; 9.75% diethylene triamine (DET), 84.3; 18.01% DET, 124; 26.72% DET, 177; 35.82% DET, 207; 8.15% triethylene amine (TET), 64.2; 16.13% TET, 81.8; 25.41% TET, 119; 11.53% monoethanol amine (MET), 23.4; 23.2% MET, 57.6; 34.69% Met, 74.5; 46.81% MET, 94.5. Recent articles and patents are reviewed. AHE (2)

Furnace Charge Descent. A. J. BOYNTON (H. A. Brassert & Co.) *Steel*, Vol. 103, Oct. 17, 1938, pp. 50, 52-53. Aside from support afforded moving charge along walls of blast-furnaces, additional support is probably provided by columns of coke extending radially from tuyeres to central mass of stationary coke. In a furnace working correctly, stock movement is largely within an annular space adjacent to walls, until a depth is reached at which the furnace diameter is equal to that of hearth. Below this point, descent is less close to walls. Descent to tuyeres is through an annulus that becomes something like a circular system of funnels as tuyeres are approached. All the slag-forming elements and the Fe descend in outer annulus. First necessity for successful blast-furnace operation is a smooth and uninterrupted descent of charge. With correctly designed furnace and reasonably good size preparation of stock the chief factor in smooth descent is a thoroughly melted and fluid slag in the furnace region that lies between a point a little above head of bosh and the point shortly above tuyeres where coke begins to burn. The furnace produces more Fe with less fuel as bosh slags become more acid (up to consistency of charcoal slags) because blast temperatures as high as the stove equipment can generate can be used. Operation with refractory bosh slags prevents full application of hot blast. Furnaces with refractory ores or high-ash coke, or those located in a moist climate, may be improved economically by reducing limestone in burden and substituting desulphurizing treatment outside the furnace or by using a tuyere that can increase the area within which the coke is burned, thus increasing ease with which stock may descend to tuyeres. A variation developed by Carl Steinbacher has a 22½° lateral angle and is claimed to have improved operation by ability to carry blast temperatures above 1600° F. with uniform blast pressure and stock movement. Probably this tuyere causes change in the radial coke piers between the tuyeres to permit easier descent of charge. MS (2a)

Hot Blast Stoves. JAMES P. DOVEL. *Steel*, Vol. 103, Oct. 24, 1938, pp. 43-44. Method of increasing operating efficiency is suggested. Blast temperatures have been limited to 1300°-1400° F., as otherwise stack and peak temperature in the stove would go too high. Experiments were made using extra stoves changed every 30 min. to prevent damage to them. For each 100° F. rise in temperature, 5% ore was added. Under these conditions, stack temperatures reached 900° F., without damage to the blast-furnace equipment. About ⅝ of this waste heat was recovered by passing cold-blast counter-current through a recuperator similar to the old pipe stoves; waste-gas temperature was lowered to 400°-450° F. By mixing and burning some live gas with the inert gas entering the recuperator under thermostatic control, a straight-line heat chart is possible. Attainment of blast temperature of 1800° F., which will melt slag freely and represents ideal operating conditions, would save $1-$1.50 per ton, which can be accomplished on any furnace plant at a cost less than that of an additional stove. Equilibria between Aluminum and Sodium with their Chlorides and Fluorides in the Molten State. Contributions on Equilibria between Metals, Sulfides and Silicates in the Molten State. No. 6 (Die Gleichgewichte zwischen Aluminium und Natrium mit ihren Chloriden und Fluoriden im Schmelzflusz. 6. Mitteilung über Gleichgewichte zwischen Metallen, Sulfiden, und Silikaten im Schmelzflusz) W. JANDER & H. HERRMANN. *Z. anorg. allgem. Chem.*, Vol. 239, Aug. 12, 1938, pp. 65-81. Experimental. The reaction $3NaCl + Al \rightleftarrows 3Na + AlCl_3$ between 800° and 900° C. goes strongly to the left. The ideal mass action law is obeyed to a first approximation. The very small displacement of equilibrium with temperature is hard to reconcile with the difference in heats of formation of NaCl and $AlCl_3$, considering especially that molten $AlCl_3$ probably exists as $(AlCl_4)^-$ ions. The equilibrium $3NaF + Al \rightleftarrows 3Na + AlF_3$ is less displaced to the left at 1090° C. than in the chloride system, possibly because the Al is more strongly bound in the complex $(AlF_6)^{---}$ than in $(AlCl_4)^-$. The curve relating Na concentration in the metal to the Al content of the slag shows a decided break at 12.8% Al, the composition of $Na_3(AlF_6)$. Above this point the Na content of the metal quickly falls to around 0.004% Na, agreeing well with the Na content of un-remelted commercial electrolytic Al. If the Al content of the slag is less than 12.8%, about 10 times as much Na dissolves in the metal, and at 1% Al in the fluoride, the Na content of the metal rises to 0.1%. From the equilibrium constants above and below 12.8% Al, the dissociation of the $(AlF_6)^{---}$ complex ion could be determined. In pure cryolite melts this amounts at most to 1-2% at 1090° C. HFK (2b)

The Dwight-Lloyd Blast Roasting Section for Sintering Lead Ores at the Broken Hill Assoc. Smelters Proprietary, Ltd., Port Pirie, South Australia. P. J. WALSH. *Proc. Australasian Inst. Mining Met.* No. 107, Sept. 30, 1937, pp. 133-156. Descriptive. Average composition of charge for year ending July 1, 1937, was Pb concentrate 50.89, limesand 4.20, siliceous ore 5.24, electrolytic Zn Coy's residues 8.28, ironstone 1.17, crushed quarry slag 4.63 and granulated slag 25.59%. Detailed chemical analyses of concentrates from various mines and of the other components of the charge are tabulated. A portion of the S is eliminated in a preroast on standard Dwight-Lloyd machines. This sinter is crushed and reroasted on D-L's. Final sinter analyzes Pb 47.12, SiO_2 7.43, FeO 14.95, MnO 2.56, CaO 5.59, Zn 10.0, S 2.1% and Ag 17.5 oz./ton. Baghouse material from preroast analyzes SiO_2 0.4, FeO 1.7, MnO 0.38, CaO 0.96, MgO 0.18, Al_2O_3 0.12, Zn 2.35, S 9.2, Cl 4.8, Cu 0.12, As 0.33, Sb 0.16, Cd 1.194, Pb 65.0% and Ag 12.4 oz./ton; dust from final roast is similar. Baghouses, sintering machines and accessories are described. AHE (2b)

Progress in the Field of Metal Separation (Fortschritte auf dem Gebiete der Metalltrennung) W. KROLL. *Metall u. Erz,* Vol. 35, Nos. 10, 11, 1938, pp. 252-254, 282-286. Discussion and review of literature. The applications and limitations of metal purification of metals by oxidation, and the possibilities in purification through the introduction of metals having high affinities for the impurities, are considered. A theoretical treatment of metallic systems, intermetallic compounds and their heats of reaction precedes a discussion of practical applications. Many possibilities for the use of Si, B, C, Zn, Al, alkaline and alkaline earth metals as purifying agents are considered. Some of the more important applications are summarized in the Table:

Base	Impurity	Present as	Precipitant	Precipitate
Pb	Bi	In soln.	Ca	Bi_2Ca_3
Pb	Sb	" "	Na	NaSb
Pb	As	" "	Na	NaAs
Pb	Au	$AuPb_2$	Zn	Au_2Zn_3
Pb	Ag	In soln.	Zn	Ag_2Zn_3
Pb	Cu	" "	Si (Al)	Cu_3Si
Pb (Tl, Bi)	Cu	" "	S	Cu_2S
Sn	Sb	" "	Zn	Sb_2Zn_3
Sn	Sb	" "	Na	Na_3Sb
Sn	As	AsSn	Mg (Na, Ca)	NaAs
Sn	Fe	Fe_3Sn	Si	FeSi
Sn *	Cu	Cu_3Sn	Si	Cu_3Si

Physico-chemical Effects of Supersonic Waves (Physikalisch-chemische Wirkungen von Ultraschallwellen) E. HEIDEMANN. *Arch. Eisenhüttenw.,* Vol. 12, Oct. 1938, pp. 185-193. Descriptive. Magnetostrictive, piezo-electric, and air jet methods of producing supersonic waves are briefly discussed. Conditions of labile equilibrium are disturbed by supersonic waves. In liquids, the waves may cause chemical reactions to start by activation of dissolved gases. The waves may cause highly polymerized substances to form. Surface passivity is decreased and the electrolytic deposition potential of gases is generally lowered. The waves also have photochemical effects producing luminescence in liquids. In colloids, dispersion and coagulation may be produced in liquids and in aerosols. Dust and moisture may be separated from smoke and fog. Metals may be improved by supersonic waves—grain refinement was produced in light metals and low melting alloys. While the waves can no doubt be applied for test purposes, no such practical uses have yet been made. SE (3)

Italian Plant Features High Frequency Furnaces. M. KAUCHTSCHISCHWILI. *Iron Age,* Vol. 142, Sept. 22, 1938, pp. 40-44. Practical description of high frequency furnaces at the works of Cogne Co., Aosta. Furnace plant consists of 4 furnace units of 8 tons, 6 tons, 1760 lbs. and 330 lbs. each. Advantages claimed for high frequency furnaces are: Production of absolutely pure and high grade products, their instant readiness for operation, convenient regulation and high degree of economy. Includes tables giving operating characteristics for both the 6 and 8 ton furnaces for a certain period. VSP (3)

Induction Furnaces for Rotating Liquid Crucibles. E. P. BARRETT, W. F. HOLBROOK & C. E. WOOD (U. S. Bur. Mines) *Metals Tech.,* Vol. 5, Dec. 1938, T. P. 986, 12 pp. Descriptive. A high-frequency laboratory furnace with a rotating liquid crucible was used in certain slag-metal studies. Details of construction of 3 such furnaces are given. One furnace held 4½ lbs. of molten ingot Fe and, when rotated at 280 r.p.m., formed a liquid crucible approximately 2¾ in. internal diameter at the top by 2¼ in. deep. JLG (3)

Patterns Must Be Good. VAUGHAN REID (City Pattern Works) *Foundry,* Vol. 66, Oct. 1938, pp. 26-28, 50; Nov. 1938, pp. 27-28, 78. Practical discussion. The importance of proper apprentice training is considered and pattern design, use of proper lumber and method of construction described. For master pattern work, northern cork white pine is recommended, while for working patterns, Mexican mahogany is suitable. If metal pattern castings with smooth finish where they will not be machined is wanted, white pine should be used for master patterns. Flake glue seems to be the best. As for shellac, a grade A orange flake shellac free from rosin and not bleached with arsenic is recommended. VSP (3)

Seals Mold Surface without Flame. A. H. WAYCHOFF. *Foundry,* Vol. 66, Sept. 1938, p. 66. Brief practical description of a method of curing trouble with molding sand cutting or sloughing on small intricate castings. Use a fly sprayer and fill with Na_2SiO_3 and H_2O in equal proportions and spray mold face lightly with mixture, which will dry quickly. Spray face again heavily and let dry for about 30 min. Treatment prevents sand cutting by hot metal and makes a smooth casting without sand holes. May be used in casting brass, Al, Cu or Fe. VSP (3)

Shrinkage and Contraction of Cast Iron. A. A. TIMMINS. *Foundry Trade J.,* Vol. 59, Sept. 15, 1938, pp. 191-193. Review plus original research. Cast Fe shows 3 distinct volume changes: (1) During the liquid state (liquid shrinkage), (2) solidification shrinkage, and (3) solid shrinkage. Liquid shrinkage is directly proportional to the temperature drop. Composition does not materially alter the volume change. Solidification shrinkage is governed by: (1) The C content, and (2) the condition of C. White irons all show a volume decrease on solidification; this decrease is a maximum at 1% C and a minimum at 4.3%. In gray Fe there is also a contraction in volume when the C is low, but as the amount of C is increased, the contraction decreases, and is eventually offset by an expansion when C reaches eutectic composition. This is because the formation of graphite during solidification causes an increase in volume. Solid contraction depends on composition and the rate of cooling of the Fe. White irons contract in a manner similar to pure metals, except that at about 700° C. an expansion occurs, owing to the change of austenite to pearlite. Low-phosphorus gray irons contract to a lesser degree, because some graphite is precipitated during cooling in the solid state, with an accompanying expansion that tends to offset the normal contraction. Therefore, the addition of carbide stabilizers or faster rate of cooling will increase the contraction by retaining more C in the combined form. High-phosphorus irons contain large quantities of phosphide eutectic that remain liquid after the main part of the Fe has solidified, and on solidifying at 950° C. give an expansion. The effect of total C and P on an Fe containing 2% Si in the high C series was investigated. Porosity appeared at 0.3% P and increased in amount as P was raised. With the lower C (2.6%) porosity did not appear until about 0.75% P was reached. Thus, as P is raised the C content must be progressively decreased in order to have castings free from porosity. Both Si and P increase porosity when the total C is high. The porosity present in high C irons may to a large extent be due to the openness caused by coarse graphite flakes. Si and P lower the amount of C required for the eutectic composition by the amount equal to 0.3% for every per cent. When a large mass of high-C iron containing high Si or P cools down, a certain amount of graphite will be precipitated before the Fe solidifies, and, having greater facility for growth, will be present as coarse flakes imparting openness to the Fe. As the Fe is still liquid, these constituents cannot cause any useful expansion. When the Fe freezes, there is less C available for expansion and the Fe is porous. Influence of section thickness, effect of pouring temperature, contraction and its relation to warping and cracking are also discussed. AIK (3a)

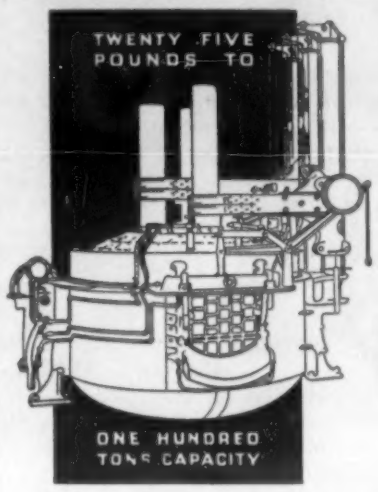
Desulphurization of Pig Iron (Beiträge zur Entschwefelung des Roheisens) W. OELSEN. *Stahl u. Eisen,* Vol. 58, Nov. 3, 1938, pp. 1212-1217. Original research. After a brief discussion of the fundamentals of desulphurization of pig Fe with Na_2CO_3 and Na silicates, and of the detrimental effect of SiO_2 in the slag and Si in the pig Fe, the favorable effect of CaO on desulphurization is brought out. CaO not only combines with some of the SiO_2, but also makes the slag more basic and combines to form CaS. CaO is especially effective after it dissolves in the slag, and additions of fluorspar help bring this about. The presence of even a small content of Mn in the pig Fe strongly increases the desulphurization by means of Na_2CO_3. The desulphurizing effects of the alkali carbonates are shown, Na_2CO_3 being by far the strongest and the effects of the others decreasing in the following order—K_2CO_3, $BaCO_3$, $SrCO_3$, $CaCO_3$. The addition of fluxes, such as CaF_2, $CaCl_2$ and other chlorides greatly increased the desulphurization, not by the action of the fluxes themselves but because they made the CaO and $CaCO_3$ fluid, in which condition the latter could react with and remove S. Na_2CO_3 is a very good flux for $CaCO_3$ but not for CaO; with $CaCO_3$, Na_2CO_3 forms a low melting (813° C.) double carbonate $Na_2Ca(CO_3)_2$. In line with the generalization that desulphurization takes place more readily under reducing conditions, it is shown that basic Bessemer and basic O.H. slags have a much stronger desulphurizing action on pig Fe than on steel. SE (3a)

The Effect of Deoxidation Treatments on the Ductility of Cast Steels. ALBERT P. GAGNEBIN (Internatl. Nickel Co.) *Trans. Am. Foundrymen's Assoc.,* Vol. 46, Sept. 1938, pp. 133-155. Research. The ductility of heat-treated cast steel is directly related to the distribution of sulphide inclusions. Steels with chain-like sulphides, arranged in a network around the primary grains, have low ductility because stress concentrations cause failure through the sulphide links, whereas steels with globular sulphides randomly distributed have high ductility. The arrangement of the sulphides depends largely on the O content of the melt, a high O content causing random distribution and a low O content resulting in the network formation. A critical amount of O is required for sound, ductile steel, and it is difficult to control this important variable; porosity may develop because of insufficient deoxidants, or low ductility may result because of a deficiency of O promoted either by reducing conditions during melting or by the use of a strong deoxidizer, such as Al. A melting practice was developed involving oxidation of the melt, then deoxidation with Si-Mn, Ca and Al, which thoroughly kills the steel, produces random sulphide distribution and consistently results in steels having high ductility, high impact resistance and high yield ratios. CEJ (3a)

Freezing of Rimmed Steel. HENRY D. HIBBARD. *Iron Age,* Vol. 142, Oct. 13, 1938, pp. 69-70, 72, 74, 76. Practical description of what happens during teeming and freezing of rimmed steel by considering the sequence of gas liberation in the mold, and results of such liberations on character of steel ingot. Skin-holes have been found filled chiefly with H_2 gas, and intermediate holes chiefly with CO. Central holes are thought to be filled with N_2 or NH_3. Sources of H_2 in fluid steel includes: (1) That in crude Fe of the charge; (2) H_2O vapor or steam in the air used in making producer gas; (3) H_2O vapor in the air used for combustion; and (4) H_2O vapor formed by combustion of H_2 in fuel. The only agency that drives off H_2 is the boil. Mn tends to check boil and, for this reason, should not be too high in charge. Cooling and freezing of metal are gradual and continuous throughout, from beginning of teeming until ingot is solid. The most important effect of effervescence in the mold is to carry off H_2 that survived the boil. Proper effervescence in mold is essential. If rate is too slow, H_2 holes form too near the surface because saturation comes sooner. Considers also segregation and scum formation. VSP (3a)

New Resistance Melting Furnaces (Neue Widerstandsschmelzöfen) O. GENGENBACH. *Elektrowärme,* Vol. 8, Oct. 1938, p. 260. Recent investigations of the change in charge composition during melting in a furnace with a graphite heating element showed that no increase in C occurs, and that rather, especially in high-alloy steels, a slight loss in C takes place. The results of 8 melts of tool and rustless steels of various composition are given in detail; the melting temperatures were between 1500 and 1600° C. The furnace had a lining of corundum cement. The average melting time was 54 min., and the average energy consumption 1 kw. hr./kg. Ha (3a)

Influence of Some Melting Factors on the Quality of Roller Bearing Steel. A. F. MYRTSYMOV. *Metallurg,* Vol. 13, Jan. 1938, pp. 39-54. In Russian. Practical. The most successful means to combat oxides in roller bearing steel are as follows: Proportioning the charge so that, upon melting, it will have not less than 1.35-1.40% C and not less than 0.5% Mn. The boil should last for 1 hr., 10 min. Mn should not drop below 0.20% during melting. At the end of boiling, the C should be 0.80-0.85%. Refining under a carbide slag should last for 2 hrs. or 2 hrs., 15 min. to carburize the bath by 0.05-0.10%. BZK (3a)



Open Hearth Design and Construction. GEO. L. DANFORTH, JR. *Blast Furnace Steel Plant,* Vol. 26, Dec. 1938, pp. 1183-1187. Practical. Outlines lay-out and equipment of modern open-hearth steel plant and discusses design and construction of a modern 125-175 ton open-hearth furnace. Pan-type hearth is generally preferred. For a furnace tapping 150-ton heats, the bottom could well consist of 3½ in. of insulation. 7 in. of first quality firebrick, 4½ in. of chrome brick, 9 in. of magnesite brick and 19 in. of sintered magnesite mixed with 15-20% of open-hearth slag. Hearth area should be 5-5½ sq. ft. per ton steel cast per heat, when hearth is measured on sill elevation inside of 18 in. of brickwork in front and back walls and 22½ in. at ends. Binding should be of rigid or semi-rigid type and self-supporting. Front buckstays should be of slab type, H_2O cooled. Rear buckstays should be of slab type, formed with proper angle for full sloping back wall. Port end and slag pocket binding should be of heavy steel sections. Door and door-frame should be H_2O cooled, the latter tapered. Prefers straight ring ribbed roof. 18-in. roof with 22½-in. ribs gives most economical total results on a 150 ton furnace, and should be good for at least 350 heats. Skewback channels on entire roof should be suspended on rods rather than fastened rigidly to buckstays. Venturi-type port should be used so that flame extends 2/3 the distance from port to port and does its maximum work on incoming end of hearth. When preheated gas is used for firing, 2 slag pockets divided by a substantially built, gas-tight division wall are required. Size of air slag pocket should be 1½ times that of gas pocket. Regenerator chambers should be of ample cubical capacity, but need not be oversize. Prefers chambers with common division wall. Air chamber should be 1½ times as wide as gas chamber, and spring of the 2 roofs should balance their thrusts. Checkerwork should provide stable construction, adequate brick mass for heat storage, large amount of exposed brick surface for heat transfer, and passageways for free and well distributed gas flow, and should have reasonable cost for installation and maintenance. Brick shape used mostly is 9 x 3 x 4½ in. MS (3a)

The Strength and Ductility of Cast Steel during Cooling from the Liquid State in Sand Molds. Part II. H. F. HALL. *Iron Steel Inst., Third Report Steel Castings Res. Committee,* 1938, pp. 73-86. Original research. Tensile tests were made with apparatus described in the Second Report for determining the properties of cast steel during cooling in the mold. An increase in the Mn content to 1.2% in 0.18% C steel caused a very slight lowering of the temperature at which ductility set in, followed by a rather quick increase in tensile strength and elongation. A further increase in Mn to 2.5% had relatively little effect. High S (0.07%) caused a pronounced lowering of the temperature at which the steel acquired ductility and a marked decrease in tensile strength at temperatures down to well below 1200° C. Tests were also made on high-C and high-alloy steels, and on low-C steels at a slower rate of straining. A test to indicate the susceptibility of a steel to hot tearing was developed. It consisted of a casting composed of a set of test bars of graduated size. Each test bar possessed end flanges and an enlarged middle portion, or bulb, which, by reason of its delayed cooling, predisposed this part of the bar to failure. These bars fractured by contraction pull when critical values of the bulb dimensions were exceeded. The controlling factor could be varied by a change in the ratio either of the length or of the diameter of the enlarged portion to that of the rest of the bar. Such a casting, when used in connection with the tensile tests, would afford a direct comparison of the susceptibility to contraction cracks with the tensile data determined. For Part I, see *Metals and Alloys,* Vol. 8, Aug. 1937, p. MA 507 L/4. JLG (3a)

Heat Transfer. C. H. VOM BAUR. *Steel,* Vol. 103, Oct. 31, 1938, pp. 40-41, 62. Practical. Limiting the rate of heat input to an electric arc melting furnace resulted in increased economy and efficiency. As heating or melting of metal is limited by efficiency of heat transfer through it, application of heat at rates above this value adds to losses. Results of 377 heats in a 2-3 ton Héroult furnace, used for making acid steel for casting from steel scrap, are presented. Voltage was 110 volts per phase, inherent reactance was 10-12%, and no choke coil was used. After a campaign operating with all power available during melting, charging and melting practice were changed, graphite electrodes used and power reduced from 1900 to 1520 kva. Best results were obtained by using about 360 kw. per ton charged during the melting period. Comparison of 105 heats in each campaign, with the same sidewall number, showed an average of 694 kw-hr. per net ton when using all power available, and 647 with reduced power. Difference in kw.-hr. during this time was 15,400, or, at $.016 per kw-hr.; $246.40 more for electricity and $36.75 for electrodes. Time saved was only 2½ hr. When a 12-in. diameter C electrode, formerly used, was too short to function, the entire electrode aggregate was pulled out, thus losing heat in the hot end. In the new set-up, a new 8-in. graphite piece was added to the hot remainder in furnace, resulting in a saving of about 38 kw.-hr. per net ton. MS (3a)

Mechanism of Solidification and Segregation in a Low-carbon Rimmed-steel Ingot. ANSON HAYES (Am. Rolling Mill Co.) & JOHN CHIPMAN (Mass. Inst. Tech.) *Metals Tech.*, Vol. 5, Dec. 1938, T. P. 988, 41 pp. Original research. An experimental and theoretical study of segregation in rimming-steel ingots of low-C steel is presented. According to the general theory developed, segregation results from the distribution of impurities between solid and liquid. A second major factor is the formation of an enriched film in the liquid adjacent to the solidifying interface and the entrapment of part of this film in the growing crystals. This entrapment is in turn greatly affected by rate of solidification and rate of stirring, the latter being almost entirely dependent on gas evolution. A further contribution is the loss of C and O by gas evolution and of the latter by precipitation of non-metallics. A mathematical treatment is presented that applies to a simplified hypothetical type of segregation in which equilibrium exists between solid and liquid phases, and the enriched film is completely mixed with the bulk of the solution. Such a process would yield the maximum segregation. The literature on the distribution of impurities between solid and liquid Fe is critically reviewed in the light of thermodynamics, and a table of distribution ratios and segregation coefficients is given. The ingot selected for experimental study was from a heat of mild steel, which has been used in the previously reported study of evolution of gases. The ingot was sampled from surface to center at points corresponding to 1/5, 1/2 and 4/5 of its height. The study included determinations of O and N by vacuum fusion. As solidification proceeds the concentration of impurities in the solid metal decreases to a minimum at a depth of 2 to 3½ in., then increases to a maximum at a depth of 4 to 4½ in. where the secondary blowholes occur. From this depth to the center the composition is practically constant. Longitudinal segregation of impurities towards the top of the ingot is particularly noticeable in connection with S and C. The average composition of the ingot, found by integrating the analytical results, is in agreement with the ladle analysis, except for C, where it is 0.028% lower, and O, which was not included in the ladle analysis. From the ladle and ingot analyses, the gas-evolution data, and from samples taken from the residual liquid during solidification, it is shown that the total amounts of both C and O in solid, liquid and gas phases during solidification are essentially constant. A study of the distribution of non-metallic inclusions was made. In the further development of the theory of segregation, based on results of experimental study, it was necessary to estimate carefully the composition of the liquid during solidification. It is shown that a vertical concentration gradient exists during the rimming period and that it gives rise to longitudinal segregation. The cause lies in the elevation of parts of the enriched film by upward currents near the solid surface. The entrapment of a fraction of the excess impurities in the enriched film is studied mathematically and the fraction entrapped is calculated from the simultaneous compositions of solid and liquid metal. S and Cu show essentially the same entrapment, while a much smaller fraction of C and O is entrapped. The entrapment figures for S are considered more dependable than those for the other elements. Assuming that the fractions entrapped are the same for Mn and Cu as for S, it is possible to compute the segregation curves for these elements in the middle cut of the ingot. The calculated curves are in good agreement with the analytical results. Similar methods are applied to the entrapment of C and O on the basis of the assumption that part of the enriched film is evolved as gas and that the fraction of the remainder entrapped in the solid is the same as for the nonvolatile elements. On this basis the fraction of the film evolved as gas is computed, as well as the total weight of C and O evolved from the film. The film loses about 3/10 of its C content and more than ½ of its O. The total C and O losses are known from the rate of gas evolution. The greater part of the C and less than ½ of the O evolved have their origin in the enriched film itself, the remainder coming from the adjacent liquid. JLG (3a)

Judging the State of Refinement in the Basic Bessemer by Analyses of the Outgoing Gases (Beurteilung des Ablaufes des Frischens in der Thomasbirne mit Hilfe der Abgasanalyse) R. FRERICH. *Stahl u. Eisen*, Vol. 58, Oct. 20, 1938, pp. 1138-1143. Review plus original research. The outgoing gases during the basic Bessemer blow were determined, data being presented mainly on the relative amounts of CO and CO_2 given off during the course of the blow. While the C is being burned out, the outgoing gases contain about 30% CO and 5% CO_2. The author has attempted to calculate the degree of oxidation of the bath from the amount of O put into the blast and from the amount of CO and CO_2 given off. At the height of the blow, when the C reaction with O is very lively, there is a slight reduction in the FeO content of the bath. This is only while there is still considerable C in the bath; as soon as the C burns down to below about 0.2% the bath is very rapidly oxidized. Rapid determination of the outgoing gases may prove of aid in controlling the Bessemer blow. SE (3a)

The Graphitization of Cast Iron (Ueber den Vorgang der Graphitisierung des Gusseisens) E. PIWOWARSKY. *Giesserei,* Vol. 25, Oct. 24, 1938, pp. 523-533. Review plus research. The process of graphite formation is well understood for C- and Si-rich cast Fe, in which the graphite can crystallize directly from the melt; not so simple, however, are the conditions permitting direct or indirect graphite formation in Si-poor cast irons. Exhaustive study of these conditions by means of cooling curves showed that graphitization is based on 3 phases, a eutectic crystallization, an exothermic disintegration process, and a strongly endothermic transformation, which is connected with an endothermic dissolving process. The varying sequence of these 3 processes is the reason for the different characters of the S-shaped cooling curves. Eutectic crystallization occurs from both the solid solution-graphite mixture and the solid solution-carbide mixture. The exothermic disintegration consists very likely in a precipitation of elementary C from a complex silico-carbide. The third phase, which is connected with a temperature drop of 30°-50° C., is probably due to the transformation of the α-Fe liberated in the disintegration phase, into γ-Fe and to the diffusion of part of C into the new γ-Fe. These 3 stages are discussed theoretically and thermal equilibrium calculations are made to show the correctness of the deductions and the agreement with experimental findings as revealed in the micrograms. Also, the anomalous ferrite formation in thin-walled castings occurs usually if the Si content of the α-Fe is so great that the γ-transformation is partly or entirely suppressed. 18 references. Determinations of the Viscosity of Molten Pig and Cast Iron by a Torsion Method (Bestimmung der inneren Reibung von Roh- und Gusseisen nach den Torsionsverfahren) E. DIEPSCHLAG & O. GESSNER. *Z. anorg. allgem. Chem.,* Vol. 239, Sept. 3, 1938, pp. 197-215. Critical review plus research. The existing methods for determining viscosities of liquids and of molten metals are carefully reviewed, and it is shown that a torsion viscosimeter of a type theoretically treated by Margules should be most suited for studies on molten metals. A rotation viscosimeter was designed and constructed that may be used for determining the absolute viscosities of liquids and metals at high temperatures. Measurements made on water, oils and mercury at room temperature were in excellent agreement with published results obtained by various methods. All the results obtained on molten metals, however, appear to be much higher than any previously published values, which have always indicated that the viscosities of molten metals are of the same order of magnitude as water. The values here obtained on molten Fe are 50-100 times as great, and correspond to the viscosities of heavy machine oils. Since there are no other data at present that were obtained by the torsion method, it is impossible to say whether the absolute viscosities obtained are correct as they stand or whether they are the result of an undiscovered source of experimental error. The present method seems to be sensitive, easy to use, and gives reproducible results. The viscosities of a number of pig and cast irons were determined at various temperatures above their melting points. HFK (3a)

The Effect of Treating Cast Iron with Caustic Soda. T. L. JOSEPH, F. W. SCOTT & M. TENENBAUM (Univ. Minnesota) *Metals and Alloys,* Vol. 9, Dec. 1938, pp. 329-335. This article deals with the treatment of gray Fe with caustic soda in respect to the following: Elimination of S, changes in chemical and oxide analysis, transverse tensile strength and microstructure. A method of applying caustic soda below the surface of the metal is described. A mechanical drawing of the apparatus used is included. The possibility of such a method may be of interest to blast furnace operators because there is a need for a means of applying desulphurizing agents with alkali bases so as to obtain greater contact with the metal and more complete reaction before the alkalies are volatilized. All additions were made to one ladle, which received the metal directly from the cupola spout. The end products of the chemical reactions were gases, fumes and slag. Appreciable reductions in the S content were observed, which in turn materially increased the transverse strength of test bars cast in dry sand molds. Tests showed that the efficiency of the caustic soda was decreased as the percentage of S decreased. The addition of NaOH to gray Fe had the tendency to cause the graphite flakes to become thinner and less blocky, as shown by 12 photomicrographs. CWH (3a)

Three Part Molding on Shaking and Lifting Molding Machine (Dreiteiliges Formen auf Rüttel- und Pressabhebeformmaschine) PAUL FRECH. *Giessereipraxis,* Vol. 59, Nov. 20, 1938, pp. 475-477. Description of a molding machine for a special type of casting, *viz.* cast Fe hollow bodies in which the outer and interior dimensions, *i.e.* the wall thicknesses, should be absolutely true to dimension, and the castings absolutely free of slag inclusions and pores. As the casting required 3-part molding, 3 molding plates and 3 molding machines are provided. The machines used are compressed air operated shaking molding machines, to attain uniform strength of the molds and high production capacity. The molding procedure is considered at length. GN (3a)

Control of Open Hearth Slags? *Blast Furnace Steel Plant,* Vol. 26, Oct. 1938, pp. 991-994, 1037. Description of some plant experiences with slag control. In order to determine what FeO in slag was desired, rolling results were checked against FeO, but no correlation was found. As a large part of the production was rimming steel, it was decided to concentrate on this type. Trying to control FeO by adding roll scale led to difficulties. However, investigation showed that heats high in FeO had low SiO_2 slags, those low in FeO had high SiO_2 slags, those with proper FeO had medium SiO_2 slags, and the sum of FeO, SiO_2 and CaO always was about the same. This indicated that by holding CaO constant, FeO could be changed by changing SiO_2. On heats with high FeO and C higher than desired, adding sand to slag proved to be a cheap way of lowering C and balancing up slag. When SiO_2 in slags was above 19%, many heats had high S, suggesting use of more CaO. Most of the above was determined after the heats were in the ladle. To use this information early in the heat, viscosity and pancake tests of slags were tried, but these were unsatisfactory. A rapid chemical method of determining SiO_2 in slag was developed, and the results were found to check better than the FeO determinations. Now slag samples are analyzed as soon as possible for SiO_2 and FeO. If SiO_2 is high, CaO is added. If SiO_2 is low and FeO fairly low, no additions are made for a while. If SiO_2 is low and FeO high, sand is added, provided there is plenty of C. Melters were able to come within 1% of the final SiO_2 desired most of the time. SiO_2 determination also helped with soft heats, where formerly erratic results were obtained when pig-Fe was added to raise C. Now if soft heat has low SiO_2 and high FeO, a little ferrosilicon is added before pig-Fe. If SiO_2 is high, pig goes in alone. It was decided to keep FeO high, so as to get good rimming action, which meant holding SiO_2 well below 16%. However, this required more CaO and longer time per heat, and the steel tended to be sluggish. Checking of a large number of tapping slag compositions against defects showed that about 19% SiO_2 was the optimum amount. Nevertheless, if the author [evidently a superintendent] wishes to be sure of a special heat, he still relies upon the judgment of the first helper." MS (3a)

Theory of Hydrogen Elimination During Electric Steel Making. N. CHUIKO. *Teoria i Pract. Met.,* No. 7-8, 1938, pp. 48-55. In Russian. An extended original investigation from the physical chemistry standpoint. The elimination velocity of H_2 from molten steel is directly proportional to the H_2 concentration in the metal. A study of a large number of heats shows an always present drop in H_2 content during boiling which is greater with a higher gas content. Pronounced deviation in the numerical values recorded is associated with simultaneous H_2 absorption taking place during boiling, hydrogen content in the furnace atmosphere varying between 1.83 and 26.4%. With low carbon elimination rates, H_2 absorption most strongly affect the reactions of C removal, particularly when H_2 concentration is low. When C is eliminated at a lesser rate than 0.1% per hour, H_2 is not removed. On this account, a C elimination rate of 0.2-0.3% per hour can be recommended in acid furnaces without overoxidation of the metal. H_2 content in acid steel varies between 0.001-0.00173% after melting down and between 0.00062 and 0.0008% at the end of boiling. In basic steel the content of the gas ranged from 0.002% after melting down to 0.0005% after boiling. (3a)

Teeming Temperatures. ERWIN H. WALDMAN (Andrews Steel Co.) *Steel,* Vol. 103, Nov. 21, 1938, pp. 44-45. Practical. Recommends use of optical pyrometer as a control instrument to aid in improving open-hearth practice, and gives details of procedure. Melter foreman should be the man to use the pyrometer. When heat is ready to tap, he should make the usual tests, and if heat is found ready to tap, pyrometer should be used. Before these temperature tests are made, all additions to be made in furnace should be completed. Readings should be taken of steel and slag inside of furnace and of steel stream as it flows from runner into ladle and as third ingot is being poured. Readings, furnace conditions, teeming practice, etc., are recorded and, after heats are followed through to completion, correlated so as to determine standard tapping and teeming temperatures. To secure such temperatures for every type and classification of steel made, at least 20 data temperatures should be obtained by each melter for each and every kind of steel made. A different standard temperature for a certain kind of steel may be assigned to each melter, if advisable. Use of pyrometer will insure continuity of quality and uniformity, insofar as temperature factor is concerned. MS (3a)

Electric Furnaces in European Steelworks. D. F. CAMPBELL. *Iron Steel Inst.,* Advance Copy No. 5, Oct. 1938, 14 pp. Review. Modern European practice with arc and induction furnaces is described. Electric furnaces for smelting Fe ore are briefly discussed, and steel-making furnaces described in detail. The relative merits of hydraulic and electric regulation of electrodes, fixed and removable roofs, various types of charging baskets, fixed and rotating hearths, and amorphous, graphite and Soderberg electrodes are considered. JLG (3a)

Critical Consideration of Methods Devised for Saving Coke in Cupola Melting (Kritische Betrachtung von Verfahren, die zwecks Brennstoffersparnis beim Kupolofen erdacht sind) BERNHARD OSANN. *Giessereipraxis,* Vol. 59, Oct. 23, 1938, pp. 435-438; Nov. 6, 1938, pp. 462-465. Practical. Saving of coke in cupola melting should not be overemphasized. The heat balance of a cupola is given. Coke consumption of 9% in melting is considered to be normal. Among the methods of decreasing coke consumption are: (1) Preheating the blast, a practice that dates back to 1832. The Schürmann cupola working with preheated air is described. (2) Use of cupola with water injection, still a doubtful method. (3) Melting with enriched blast, a practice that is too expensive. (4) Melting with dried air (Gayley). (5) Use of cupola with blast in the upper part of the cupola (Poumay method), said to be of doubtful value. (6) Utilization of waste gas heat to generate steam and hot water. (7) Use of Ibbrügger cupola with utilization of waste gases for melting purposes (this method has been discarded). (8) Use of cupolas with oil, powdered coal and gas firing, which are all uneconomical. (9) Methods of treating the coke with lime or clay (Corsalli and Magyar method, no longer in use). (10) Use of cupola with electric heating. All of these methods are critically considered Most of them are unsuccessful. 18 references. GN (3a)

The Fluidity of Iron-carbon and Other Iron Alloys. Part A.—The Fluidity of Alloy Steels. J. H. ANDREW, G. T. C. BOTTOMLEY, W. R. MADDOCKS & R. T. PERCIVAL. *Iron Steel Inst., Third Report Steel Castings Res. Committee,* 1938, pp. 5-32. Original research. Fluidity tests carried out with the standard spiral mold described in the Second Report were extended to Fe-C alloys containing varying amounts of Si, Cu, Cr and Ni, respectively. In order to correlate the fluidity numbers with the liquidus and solidus ranges, freezing- and melting-point determinations were made on all alloys dealt with. The system of plotting the fluidity values at temperatures 50° C. above the liquidus curve was adopted, but a better system is to plot the temperature at which the fluidity is 12 in. against the composition. The curves derived in this manner follow the liquidus curves very closely. It is evident from the results that temperature is the all-important factor with respect to fluidity, composition in itself playing a minor part. For previous work, see also *Metals and Alloys,* Vol. 8, June 1937, p. MA 344 L/2. JLG (3a)

Duplexing Malleable Cast Iron. GEORGE A. SCHUMACHER (Albion Malleable Iron Co.) *Foundry,* Vol. 66, Oct. 1938, pp. 22-24, 88, 90. Practical description of the metallurgical advances made in the last 50 yrs. by the Albion Malleable Iron Co., with special reference to present day practice. Duplex melting is done in a cupola and a pulverized-coal-fired air furnace. Twenty tons of metallurgically desirable white Fe/hr. can be produced at 2900° F. Charging is done mechanically. Cupola Fe is analyzed for total C, Mn and S every ½ hr. Molding is done by mechanized line molding and heap or bench type. Molding sand moisture content ranges from 4 to 4½%, permeability 65, green compression strength 8 lb./in.², clay content 3-5% and average grain fineries 65. High grade washed round grain silica sand is used for core mixtures. Batch type annealing ovens are used with a capacity of 35 tons of castings. Annealing cycle consists of about 24-30 hrs. of preheating; 28-32 hrs. of holding at 1600° F. and 66 hrs. of cooling. VSP (3a)

Development of the Dendritic Structure of Stainless Chromium Steels (Die Ausbildung des Primärgefuges bei nichtrostenden chromstählen) H. SIEGEL. *Stahl u. Eisen,* Vol. 58, Nov. 3, 1938, pp. 1218-1225. Original research. Ingots of low C 14.5% and 17% Cr steel of 250 mm.² cross-section, weighing 400 kg., were cast and transverse sections deep-etched to reveal the dendritic structure. This was then related to the inclusion content and "temperature value" as judged by the heat input; the variables considered were: Nuclei number, crystallization rate, degree of superheat and heat gradient at the solidification surface. In the examples given the dendritic structure (depth of columnar zone and fineness of crystals in interior granular zone) could be consistently explained on the basis of Tammann's laws of crystallization. SE (3a)

Inclusions and Gases in Steel. F. F. FRANKLIN. *Blast Furnace Steel Plant,* Vol. 26, Nov. 1938, pp. 1081-1084, 1096. *Heat Treating Forging,* Vol. 24, Nov. 1938, pp. 543-546, 553. Review of literature since 1936 on effects, methods of determination, types, occurrences, distribution, and control. In controlling inclusions and gases, excess deoxidizer must be avoided. Among the practices recently introduced for reducing gas or inclusion content of steel are (a) for high frequency melting, addition of 0.2-0.4% Fe-Mn and an acid slag before melting, followed by double removal of FeO-rich slag, replacing slag with a lime-silica mixture during refining, cutting off current before adding the last deoxidizer, then cutting it in again just before tapping; and (b) for open hearth practice, either boiling for 2½-3 hrs. (no more nor less), or agitation of the bath, *e.g.* by bubbling a neutral gas through it. The Perrin process and the use of alkali slags for removing inclusions from cast Fe are also discussed. MS (3a)

"In 1924, we purchased a 35KVA Ajax-Northrup High Frequency converter for use in the production of alloys for our research in metallography. For the most part, our work has involved studies on the graphitization of white cast iron.

"It is possible with the converter to produce the desired compositions quickly and easily. The simplicity of the alloy forming process has made it possible for the research workers to cover their metallographic problems thoroughly in a relatively short time.

"The induction furnace has been a great aid in the preparation of magnesium oxide crucibles for use in making high purity alloys. Some of our work has involved the heating of metals to high temperatures in vacuo or in inert or controlled atmospheres; the induction furnace is ideal for this kind of operation.

"Our Ajax-Northrup unit, which is one of the earlier models is still in good working condition.

"A number of Doctor's dissertations have been written here on work that has involved the use of our induction furnace. Some of these works have been published and are as follows:

Jennings, W. H., Pennington, W. A. The determination of the rates of graphitization at 925° C. in tungsten—manganese white cast iron. Trans. Am. Soc. Metals 22, 751-65 (1934).

Investigations on Transformations in Basic Open Hearth Slags During Melting, in Particular the Behavior of Lime (Untersuchungen über Umsetzungen in basischen Siemens-Martin-Schlacken während des Schmelz, verlaufes, insbesondere über das Verhalten des Kalkes) GOTTFRIED PRIEUR. *Doctor's Thesis, Tech. Hochschule Breslau.* 44 pp. The melting course of 9 experimental basic open hearth heats made with (1) high lime content in burden, (2) high limestone content and simultaneously high Si content in scrap used, or (3) low limestone content and high P content in slag. In all slag samples taken, the chemically unbound CaO content, forming a special phase, was determined by the method of Diepschlag-Matting. The investigation studied in particular the relations between (1) free CaO and burden composition, (2) CaO and the other slag oxides, (3) CaO and the acidic constituents of the slag, (4) the dissolution of FeO and CaO in the slag and the concentration of Mn and P in the heat. From the CaO concentrations found in the slags of the various heats, the course of Ca dissolution in the slag could be established. The chemical transformations in bath and slag attain an equilibrium state at a rather early stage. The location of the equilibrium is clearly related to the concentration of the slag components, and from these the course of the bath reactions can be predicted. 8 references. GN (3a)

Fluidity-temperature Relations of Cast Steels of Various Compositions. R. J. SARJANT & T. H. MIDDLEHAM. *Iron Steel Inst., Third Report Steel Castings Res. Committee,* 1938, pp. 45-60. Original research. The Ruff fluidity tester was used in the laboratory for making fluidity tests under closely controlled conditions on various steels. It was also used for some plant trials, and as a plant instrument it seemed to be practicable. There was a very definite correlation between temperature and fluidity and results were closely repeatable. Swedish charcoal Fe had greater fluidity than Armco Fe, even though the analyses were almost alike. For C steels the general form of the fluidity curves given in the Second Report was confirmed, with the exception of some divergence in the fluidity-composition curves for specified degrees of superheat above the liquidus. Additions of Al (up to 0.3%), of Si (up to 1%), and Mn (up to 1%) confer increased fluidity on low-C steel. The increased fluidity possibly results from increased deoxidation. Additions of Cu (up to 2% produce only a slight increase in fluidity, which in the case of a 2% Cu content is not increased by further additions of Si (0.5%) and Mn (0.5%). JLG (3a)

First Report of the Moulding Materials Sub-committee. *Iron Steel Inst., Third Report Steel Castings Res. Committee,* 1938, pp. 87-200. Original research. Among the subjects considered are: 1. Methods of testing molding sands for steel foundry use. 2. Relation of the "bond" in naturally bonded and synthetically bonded sands to "stripping" and "burning on," including the properties of reclaimed sand. 3. Effect of washes on stripping and the casting skin. 4. Investigation of the behavior of synthetic bonds with clean high-silica sand, weak clay-bonded sand, and influence of grain characteristics on bonding. 5. Effect of pressure on the sintering and softening of molding sands. 6. Methods for the preparation and reclamation of molding materials. 7. Investigation of the properties of core bonds. 8. Volume changes in molding sands and "compos" from 0° to 1400° C., including the effect of composition, grading, and ramming density. 9. Effect of thermal conductivity of the mold on the casting. JLG (3a)

Heavy Oil Burning and Its Control. A. J. FISHER. *Iron Steel Engr.,* Vol. 15, Dec. 1938, pp. 22-47. Practical. Modern methods of fuel engineering have made it possible to locate steel plants near the ore field and the steel consuming centers rather than near the coal fields. The first period in burning fuel oil, hand-controlled period, was from 1861 to 1932. The period 1932 to date may be called the automatic controlled period of fuel oil burning. Temperature and pressure recorder controllers, fuel oil control, oil burners and furnaces are combined to a unified oil system to obtain specific results. Furnace design is of utmost importance for an oil burning system. Various regulating and controlling devices, oil burners and oil conditioning systems are described. Combustion data and heat balance calculations are given. CBJ (3a)

Processing of a Multi-blade Water Turbine Wheel of One Piece of Cast Iron (Herstellung eines mehrflügeligen Wasserturbinenlaufrades aus einem Stück in Gusseisen) F. PASCHKE. *Giessereipraxis,* Vol. 59, Sept. 25, 1938, pp. 396-400. Descriptive. After a historical survey of making such heavy intricate castings of one piece, sweep molding applied to the particular case considered is described. Runners made by means of cores were not as successful as sweep-molded ones. The blade wall thicknesses were true to dimension; at least the differences observed were negligible. The processing time was thus considerably shortened and the production costs were essentially decreased. GN (3a)

The Development of the Open-hearth Steelmaking Processes in Recent Years in the United States of America. L. F. REINARTZ (Am. Rolling Mill Co.) *J. Iron Steel Inst.,* Advance Copy No. 12, Oct. 1938, 47 pp. Up-to-date review. A comprehensive and frank discussion of open-hearth equipment and practices in the United States. The annual capacity is now over 71,000,000 gross tons of ingots and castings. The basic open-hearth process has far outstripped in production its acid open-hearth or Bessemer rivals because of its greater flexibility from the standpoint of Fe analyses requirements, and because the basic process can use great varieties of Fe and steel scrap. JLG (3a)

Investigation of the Melting Process in a 300-ton Open Hearth Furnace. L. VLADIMIROV & G. BESKHMELNITSKAYA. *Stal,* Vol. 8, May 1938, pp. 35-41. In Russian. Practical. A 150-ton furnace that was rebuilt to hold 300 tons with a deep metal bath is compared with a 150-ton furnace operating on a 190-ton charge as follows: Average length of heat 14:54 hrs., *vs.* 12:58 hrs.; average daily production 482 tons *vs.* 360 tons; daily production per m.² hearth area 6.58 tons *vs.* 5.15 tons. Maximum production is obtained if the metal contains 1.1% C on melting, as this permits an intensive boil during the oxidation period. HWR (3a)

Casting Automotive Parts—Steel and Gray Iron Casting Methods at Ford Motor Co. of Canada, Ltd. *Can. Metals Met. Inds.,* Vol. 1, Nov. 1938, pp. 299-302. Descriptive. The melting equipment consists of two 12,000-lb. Swindell electric furnaces, one 8,000-lb. Pittsburgh electric furnace and two 10,000-lb. Brackelsberg furnaces. The metallurgical and technical methods employed in the production of the various types of castings made are described, with particular attention to the casting of crankshafts, steel hubs, camshafts and push rods. WHB (3a)

Works Results Using the Ruff Fluidity Test. T. R. WALKER. *Iron Steel Inst., Third Report Steel Castings Res. Committee,* 1938, pp. 35-43. Original research. The Ruff fluidity test was used at 2 steel foundries, and the results considered in reference to temperature of the steel as determined by an optical pyrometer and reports of the men pouring the steel. There was general agreement between fluidity and temperature and between fluidity and the workers observation on pouring. JLG (3a)

American Electric-furnace Practice. W. M. FARNSWORTH & E. R. JOHNSON (Republic Steel Corp.) *Iron Steel Inst.,* Advance Copy No. 7, Oct. 1938, 15 pp. Descriptive. Electric arc and induction furnace equipment and operation at the Republic plant is described in detail. Particular attention is given to raw materials used and the various modes of procedure in normal alloy-steel practice, stainless-steel practice and the duplex practice for making stainless steel. Logs of furnace heats are given. JLG (3a)

Melting in the Cupola (Das Schmelzen im Kupolofen) H. JUNGBLUTH & H. KORSCHAN. *Arch. Eisenhüttenw.,* Vol. 12, Oct. 1938, pp. 167-173. Practical. It is suggested that the air drawn into the cupola is burned to CO_2 at the glow zone near the tuyeres. The extent of the glow zone depends, not on the amount of coke, but on the amount of air. The increase in output with constant coke addition and increased air flow is due to the greater glow zone, which enables faster melt down of the charge. With constant air flow and increasing coke charge, coke which is not in the glow zone reduces CO_2 formed in the glow zone to CO. Under these conditions, the coke ratio is excessive and the efficiency is lower. This theory appears to be in accord with thermal data. SE (3a)

Foundry Pig Iron from Iron-poor German Ores and Its Use in the Foundry (Giessereiroheisen aus eisenarmen deutschen Erzen und seine Verwendung in der Giesserei) M. PASCHKE & C. PFANNENSCHMIDT. *Giesserei,* Vol. 25, Oct. 24, 1938, pp. 539-546. Practical. The new method of Paschke-Peetz for melting Fe-poor ores in the blast-furnace with a slag basicity (CaO/SiO_2) of only 0.8 against 1.25 in the usual process and desulphurization in a subsequent process has also influenced foundry practice in Germany to a certain extent. Mixtures of pig Fe from this acid process with scrap, ferro silicon, and other material to produce castings of desired quality are discussed and several examples are given with their physical properties. 12 references. Ha (3a)

Casting Properties of Metals (Les Propriétés de Fonderie du Métal et de la Fonte en Particulier, Conséquences Pratiques) MARCEL DUDOUET. *Bull. l'association tech. fonderie,* Vol. 12, Aug. 1938, pp. 172-177. A discussion of fluidity, shrinkage, cracks and gas pockets. Considers the effects of casting design, melting method and chemical composition on defects in cast Fe. WHS (3a)

3b. Non-Ferrous

G. L. CRAIG, SECTION EDITOR

Moulding Materials. Practice in Non-ferrous Foundries. FRANCIS W. ROWE. *Metal Ind., London,* Vol. 53, Nov. 11, 1938, pp. 471-473. The most common material for molds for non-ferrous alloys is, and always will be, natural siliceous sands. In recent years some use has been made of silica sands with additions of bonding materials. Because the thermal conductivity of the mold material influences the speed of cooling, the sand mold is at a distinct disadvantage as compared with the metal mold. The use of chills in sand molds do not give results equal to those obtained in metal molds. Centrifugal casting automatically compensates for liquid shrinkage, and produces finer grain castings. The difference in the physical properties of a small and large centrifugal casting is not as great as in a sand cast. The use of the green sand mold results in sharper castings, smoother skin, less flash and lower fettling cost. The advantages of a properly made synthetic sand are: Permeability is greater, and much greater strength is obtained. The cement-sand or Randupson process is rapidly coming to the fore. Properly made cement-sand molds have a much higher permeability than other types of molds, and possess extraordinary strength, even in very large masses. The basis is a sand of about 97% silica. This is mixed with 4-13% cement with water to ensure primary hydration of the cement only. While being rammed the molds are reinforced with Fe rods. The molds are made at a time saving of 20-60%, and require 24-72 hrs. to dry. The disadvantages of the process are: The sand has no green bond strength, the time required for air setting is usually 48 hrs., the sand must be used within 3-5 hrs. and all sand must go through a mixing plant both originally and for reconditioning. These are far outweighed by the advantages in overall labor cost saving, and technical advantages due to high permeability, great mechanical strength and freedom from scaling. It is equally adaptable to work usually done in box parts as well as work struck up in loam. It is not recommended for work usually done in green sand, such as small parts, but for all work usually done in dry sand or loam. RWB (3b)

The Relation between Casting Conditions and the Resistance of Metals and Alloys to High Pressures (Dichtigkeit von Metallen und Legierungen gegenüber hohen Drucken in Abhangigkeit von deren Gussbedingungen) G. WELTER & J. MIKOLAJCZYK. *Metallwirtschaft,* Nov. 11, 1938, pp. 1187-1191. Research. An apparatus is described wherein samples can be subjected to liquid pressures of 1000 atm. and gas pressures of 150 atm. Melting and casting conditions, such as flux, pouring temperature, size of section and location of specimen, were investigated for Al alloys. Thinner-walled sections are more dense as a rule. The same holds for Mg base alloys. Materials that exhibited no porosity under 350-400 atm. liquid pressure will show no porosity under 150 atm. gas pressure. Materials not permeable to liquids at 400 atm. will generally not leak up to pressures of 1000 atm. A Mg alloy and a Zn alloy were also briefly studied. GA (3b)

Effect of Casting Defects on the Strength of Light Metal Castings (Einfluss von Gussfehlern auf die Festigkeit bei Leichtmetallgusstücken) F. BOLLENRATH & E. SCHIEDT. *Luftfahrtforschung.*, Vol. 15, Oct. 10, 1938, pp. 511-516. Original research. Some defective castings of airplane parts made of Al and Mg alloys (analyses given) were tested to destruction under static and dynamic loads. To appraise the importance of defects in castings, one must know the regions of maximum stress in the member. Differences in structural homogeneity and wall thickness were found to exert a greater influence on the service life than blow holes, pipes and gas pockets of 3-5 mm. diam., unless the latter are located directly in the regions of maximum stress. In this case, a hole of 2 mm. diam., for instance, materially reduced the dynamic strength of an angle girder of Elektron. Changes of cross-sectional area must be free of defects. Otherwise, casting defects of 4-5 mm. diam. are admissible. Cracks and oxide skins perpendicular to the surface must be absent. Larger blow-holes of more than 5 mm. diam. and spongy castings should be rejected. Coupon tensile tests are no guarantee of the usefulness of a casting. The tests should be carried out on the casting itself, under conditions closely simulating actual service conditions. EF (3b)

A New Die Casting Method (Ein neues Kokillengiessverfahren) *Giessereipraxis*, Vol. 59, Nov. 20, 1938, pp. 481-482. Description of a new French method for making die castings of Cu alloys. Before each single casting, the heated die is immersed in a water bath in which insulating substances are suspended. The die is thus covered with a thin uniform insulating coating. Graphite, clay, Al_2O_3, ZnO, talcum, etc., may be applied as coating substances. Absolutely clean, smooth castings of high finish are claimed to be obtainable by this method, so that any subsequent treatment, such as pickling, is not required. GN (3b)

The Hazard of Sodium Metal (Ueber die Gefährlidikeit von Natriummetall) *Chem. Ztg.*, Vol. 62, Nov. 30, 1938, p. 860. Practical. Na used for refining Silumin, also reduces its grain size. About 80 g. of Na are used for a 100 kg. bath of alloy. Na is dried from kerosene by means of paper, then wrapped into Al foil and hammered to drive out the air. The package is then put into the bath and kept under the surface of the melt. Extreme caution is necessary during cutting off and handling of the metal to keep it away from moisture. Special regulations for shipment, storage and handling were issued in Germany. RPS (3b)

Influence of Moisture Content of Moulding Sand on Strength Properties of Cast Aluminium Test Bars. C. GIERDZIEJEWSKI. *Foundry Trade J.*, Vol. 59, Oct. 20, 1938, pp. 289-292. Descriptive. Test pieces cast from metal melted in identical conditions show differences in properties. These differences are small when testing chill-cast samples, but relatively important with sand-cast samples. According to Lepp (Internatl. Foundry Congress, Prague, 1933) variations of strength properties depend on the moisture content of the sand used for either molds or cores. The steam produced when pouring molten metal into the molds reacts with the metal, forming oxides. At certain conditions pockets may be formed in the molds that affect their heat conductivity, favoring local increase in temperature and pressure. Lepp's conclusions were confirmed by tests on some of the bronzes. The author also studied the effect of moisture content on the strength of test bars cast from different Al alloys. All test bars were made with one molding sand, with the permeability and strength properties controlled, leaving moisture content as the only variable. 6% Cu-Al, 10% Si-Al and Hiduminium RR50 (approximate analysis: Cu 1.40; Si 2.00; Fe 1.13; Ni 0.90; Mg 0.10; Ti 0.13) alloys were used in this test. Six specimens were cast simultaneously in molds having moisture contents of 0, 3, 5, 7 and 9%, and in addition, one chill sample was cast. After casting, the chill sample was taken out of the mold, while the sand-cast samples were left in the molds for 40 min. In 6% Cu-Al alloys, increase of moisture produced a grain refinement and increased porosity. The tests on 10% Si-Al alloy revealed that increase in the moisture caused an increase of tensile strength and a decrease of elongation, but had no influence on Brinell hardness. Test-bars cast in chill molds showed highest tensile strength but a lower elongation. For Hiduminium alloys there was some increase in tensile strength and elongation with an increase of moisture content. In all cases examined, an increase in the moisture content of the mold produced a refinement of the structure and increased porosity of the castings. AIK (3b)

Sand Cast Manganese Bronze. *Metal Ind., London*, Vol. 53, Oct. 7, 1938, pp. 347-348. Practical. This report is divided into 5 sections dealing with, molding, melting and pouring, finishing, heat treatment, and the cause and prevention of defects. Considerable latitude is permitted in the grain size of the sand used for this alloy. A sand of about AFA No. 1 or 2 grain size, D to F clay content of 5-20% and moisture content of 5-6% is suggested for this alloy. With this sand no facing is needed. The drossing tendency of the alloy makes special gating precautions necessary. Best castings are obtained by filling the mold by displacement. The alloy permits strong cores and silica sand with a good grade of core oil is suggested. All types of melting furnaces are used. Superheating is unnecessary and should be avoided. Unprotected thermocouples may be used but covered tips are finding increased favor. No deoxidizers are required, but fluxes are useful to retard
1 vaporization of the Zn. The maximum temperature in melting should be no higher than that necessary to pour satisfactory castings in the range 1775°-1925° F. Gates and risers may be removed with a band saw operated at a speed of 120-130 ft. min. For cleaning, the usual methods of sand blasting, wire brushing, pickling, and water tumbling are followed. Only very slight changes in physical properties are produced by the usual methods of heat treatment. Gas inclusions may be avoided by preventing overheating and using a nearly neutral atmosphere. By covering
2 with charcoal and using a neutral or slightly reducing atmosphere, oxidation may be avoided. In casting, misruns and cold shuts indicate too low a pouring temperature. Molding sand defects and preventions are discussed. Pb is the chief undesirable impurity in Mn-bronze; in a large casting a maximum of 0.40% Pb is permissible. For castings unlikely to meet severe stresses, an upper limit of 0.50% Pb is not excessive. RWG (3b)

Non-ferrous Foundry Practice. XII—The Production of Some Special Castings in 88-10-2 Gunmetal. J. LAING & R. T. ROLFE. *Metal Ind., London*, Vol. 53, Oct. 14, 1938, pp. 367-369. Practical. The casting of an eccentric ring (1 in. out of true circle) in a loam mold with plain type strickle boards is described. The complete mold was stove dried and the faces washed with a mixture of plumbago and talc, to which a little core gum and clay water was added and then returned to the stove to be dried. When the runner and riser bushes were made up, the job was cast in the usual manner. The various stages in the manufacture of a 27½ in. bottom half centrifugal main circulating pump casing are shown. The pattern was split on a flat plane and built up in skeleton fashion. 2 large down-gates were used, each connected to the joint flange by 4 in-gates; one gate led into the flange of the discharge branch. When the half patterns were withdrawn the mold was cleaned and finished to shape, with the loose flanges and brackets all left in position. After clay thickening, the suction branch was covered with plastic loam and the core Fe inserted; pieces of dried loam were pressed into the plastic loam. Cinders were next rammed into the center of the core, the check rings, cut water and loose pieces placed, the upper face filled with loam and the core dried with firebuckets. The completion of the half body core followed the same line. Next, the clay thickened pieces were cleaned out, the suction branch core removed and the mold dried. The mold was then assembled and dressed. It is essential to test the metal thicknesses all over the surface of the mold, and between the suction branch and body case, for a local thinness or even a misrun may occur. In the example given, the weight of metal in the ladle was about 2850 lbs., temperature 1,225° C. and time of pouring 41 secs. RWB (3b)

Non-ferrous Foundry Practice. XIII. Moulding Practice for Phosphor-Bronze. J. LAING & R. T. ROLFE. *Metal Ind., London*, Vol. 53, Nov. 4, 1938, pp. 443-445. Aside from one or two important characteristics, due to the presence of P, production methods for P-bronze are very similar to those for gunmetal. When design and volume permit, chilled castings should be used for this range of alloys. Chilling increases hardness, proof stress and ultimate stress figures, but reduces ductility in a corresponding degree.
7 As Sn and P contents increase, the effect of chilling becomes more pronounced. Annealing at 700°-750° C. will often benefit the ductility. Where design prevents the use of chill casting, local chills are often necessary. Except for very small castings it is inadvisable to use the green sand method. If chill casting is not used because of penetration, the dry sand method should be used; green sand castings are definitely inferior. When uniform soundness is essential, gating either from or near the top of the casting
8 is generally advisable. The high fluidity permits top-pouring at low temperatures in sand molds. To produce hydraulically sound castings, the use of chills at heavy sections is usually necessary, as well as keeping runners away from heavy portions. When chills are used, the metal must not strike directly on them. For dry sand work, chills should be cleaned and given a thin coat of oil. The temperature of the mold should not exceed 100° C. The use of risers should be restricted as much as possible. Small castings, poured at the correct temperature, will not require a riser if
9 gated near the top. Feeding heads are generally unnecessary. For low P content, gunmetal practice with runner bushes is suitable. For high P content, the bushes must be so designed that they can be kept choked with metal during pouring. For small work, the area of the down gate should be reduced. Of the non-ferrous alloys in common use, the pouring temperatures of the P-bronzes are about the most critical. The range of composition is very wide, and the optimum casting temperature may be below
10 1000° C. for the Cu-Pb-Sn-P alloys, or as high as 1100°-1150° C. for the low P-Cu-Sn alloys. The 10% Pb alloy must be stirred before pouring, and melting practice for gunmetal is followed. Large quantities of gear blanks are now cast centrifugally, this process not only giving a denser structure, but also permitting the selective chilling of one or more faces. RWB (3b)

4·WORKING

Forging, Rolling, Drawing, Extruding, Punching, Stamping, Shearing and Machining

S. EPSTEIN, A. W. DEMMLER AND H. W. GRAHAM, SECTION EDITORS

New Applications for Press Work. II. New Applications Possible by Increased Depth of Draw. J. D. JEVONS. *Metal Ind., London,* Vol. 53, Nov. 11, 1938, pp. 467-470. Practical. Extension in this field of application may be attributed to (1) the production of new shapes which can be produced only by deep-drawing or pressing, (2) the replacement of parts which, prior to the postulated increase in depth in draw, could be made more satisfactorily or cheaper by other methods, and (3) the elimination of interstage annealing, with consequent reduction in the cost of pressed and deep drawn articles. The bodies and mud guards of modern automobiles offer an excellent illustration as to how increased depth of draw or pressing leads to an increased field of application. Exact contour of auto head light shells has no practical significance, but the shape of the reflector is important. This introduces another aspect, namely, the value of increased accuracy, as distinct from depth. When very close conformity in dimension is required, it is customary to give the article one or more final squeezing operations between dies, a process akin to "coining" and needing very robust presses and careful tool setting. Accurate "sizing" by finishing operation enables final rectification in dimensions. In deep drawing, improvements in the quality of the metal itself, drawing technique, tools, lubricant and interstage annealing have all contributed to the more severe drawings now being used. Brass tubes deep drawn from flat blanks are cheaper and have a greater uniformity of wall thickness than tubes drawn from cast tubes or pierced billets. The interstage anneal adds to the cost and slows up the process. With constant improvements from all viewpoints, more and more drawn and pressed parts are being made almost eliminating this phase but there is clearly a limit to the amount of plastic deformation without an anneal. The value of pressing in thick sheets is well illustrated in the pressed steel auto-wheel, which is a growing application. For Part I see *Metals and Alloys,* Vol. 10, Feb. 1939, p. MA 88 L/3. RWB (D-4)

Recent Developments in Hot Rolling Mill Practice (Varmvalsverkens utveckling under senare tid) GUNNAR WALLQUIST. *Jernkontorets Ann.,* Vol. 122, No. 7, 1938, pp. 265-376. After an historical introduction, recent developments and improvements in rolling mill practice are discussed, including ovens, heating pits, roller constructions, driving mechanisms for operating the units, and the mechanical and chemical surface treatment of the finished stock. Furnaces used for heating the product are described, such as the automatic gas fired furnace, the Swedish coal tower furnace, and various recuperative devices. In roller construction, the greatest development has been in ball and roller bearings. Advantages and defects of various types of construction are pointed out. Data are presented on Swedish practice with respect to feeding devices. Developments in the roll itself are discussed with reference to the rolling of sheet from ingots; the rolling of bars, beams and heavy profile stock; the rolling of rods, wire, bands, heavy, medium and thin steel plate. An account is also given of construction and production factors affecting the process. Detailed data are given on processes for treating the surface of the finished stock. HCD (E-4)

The Honing of Cylinder Bores (Das Honen von Zylinderbohrungen) RICHARD KOCH. *Automobiltech. Z.,* Vol. 41, Nov. 10, 1938, pp. 562-563. Practical. All machining operations cause structural changes in the surface of the material and leave fibers that tend to attack piston rings. Inside grinding does not entirely solve the problem. Smoothing by hard rolls has the disadvantage of not removing material from high points. Honing, however, is a method of solving this problem. It consists of a combination of rotating and lengthwise movements with side pressure exerted by a honestone. All Fe alloys and steels of any hardness can be honed. Except for the harder brasses, non-ferrous metals cannot be honed. Applications of honing and machines, therefore, are described. Cooling media are: Kerosene or fish oil, or a mixture of paraffine oil for cast Fe and mild steel; lubricating oil for hardened parts; water or no cooling medium for brass. The operation is described. RPS (G-4)

The Deformation of Crystalline Aggregates by Rolling and Drawing (Die Verformung von Kristallhaufwerken beim Walzen und Ziehen) HERMANN UNCKEL. *Z. Metallkunde,* Vol. 30, Aug. 1938, pp. 252-258. Experimental. The mode of deformation of homogeneous and 2-phase alloys was observed during rolling, drawing and elongation by measuring the changes in dimensions of a grid scratched onto selected surfaces. Orientations of individual grains were determined in many cases. Irregularities of deformation resulting from differences of orientation were shown to be much less in fine than in coarse-grained material, less pronounced in drawing than in rolling, and greatest with uniaxial extension. Nevertheless, the transition from one grain to another was always gradual, with no sharp offsets at the grain boundaries. GD (E-4)

Some Notes on Forge Practice. J. H. HURST. *Metal Treatment,* Vol. 4, Autumn 1938, pp. 135-136. Practical. Circular porter bars, each suited for a particular size of round-headed ingots, are considered more satisfactory than any universal porter bar with set-screws or liners. Vertical light steel cylinders are less cumbrous than wooden blocks as supports while adjusting the bar. Wheels are preferred to flanged rollers for the hearths of bogie type furnaces. Reference is made to a method of changing press tools rapidly. JCC (D-4)

Structure of Iron after Compression. CHARLES S. BARRETT (Carnegie Inst. Tech.) *Metals Tech.,* Vol. 5, Oct. 1938, T.P. No. 977, 29 pp. Original research. A method of compressing specimens by rolling them successively in many different directions permitted deformation up to the limit set by the capacity of the material to flow without fracture. This and more conventional means of compression were applied to α Fe, and the results were analyzed by a special optical method, as well as by standard X-ray methods. Single crystals or individual grains of α Fe do not, in general, seek a single orientation during deformation by compression. A crystal initially having [100] near the compression axis will end as a distorted crystal with [100] parallel to the axis, while one starting with [111] near the axis will end as a distorted crystal with [111] parallel to the axis; all others cease to be single crystals and produce the structure known in the literature as deformation bands, etch bands or X-bands. The crystalline material in the bands rotates progressively as deformation continues, in a direct manner so as to bring [111] in one band and [100] in another band in positions parallel to the axis. The fraction of a crystal possessing each orientation depends upon the initial orientation. This mechanism is responsible for the compression texture of polycrystalline Fe, which was redetermined and found to be a double fiber texture with [111] and [100] parallel to the compression axis. Slip occurs on a considerable number of slip systems to produce these effects. Deformation bands have probably introduced errors in slip-plane determinations in Fe of other investigators. JLG (E-4a)

Modern Rolling-mill Practice in America (Exclusive of Continuous Strip and Sheet Mills) QUINCY BENT (Bethlehem Steel Co.) *Iron Steel Inst.,* Advance Copy No. 2, Oct. 1938, 62 pp. Descriptive. Methods and mills developed for the rolling of steel to finished products as practiced in the rolling mills of the United States are described. The first part of the paper is a synopsis of the subject, which gives a brief description of mills and practices. The appendix, forming the second part, gives more complete data on the mills and practices. JLG (E-4a)

The Development of Continuous Strip Mills. D. EPPELSHEIMER (Am. Rolling Mill Co.) *Iron Steel Inst.,* Advance Copy No. 6, Oct. 1938, 12 pp. Review. A brief historical review of the rolling of sheets as well as the previous unsuccessful attempts to roll sheets in continuous mills is given. The fundamental requirements and means for the discovery and the subsequent application of continuous strip rolling are fully explained in detail. JLG (E-4a)

Twisted Bars for Strength. *Steel*, Vol. 103, Oct. 24, 1938, pp. 40-42. Descriptive. "Isteg" steel concrete reinforcing bars, developed in Austria, are now being produced by Wickwire Spencer Steel Co., Buffalo, N. Y. The bar is fabricated by cold twisting together and stretching 2 rods in specially designed machinery that make 2 bars at a time. When made of ordinary structural billet steel, the product has a minimum yield-point of 50,000 lbs./in.^{2} When made of intermediate grade billet steel, minimum yield-point of 60,000 lbs./in.^{2} is obtained. An increase of 50% in allowable stresses is permitted, thus reducing necessary weight of tension reinforcing steel by about 33⅓%. Process removes mill scale, resulting in an efficient bond with concrete. Laboratory tests at Columbia University of Isteg, plain round and deformed bars showed an average of 47.2% increase in yield strength for the twisted bar. Reinforced-concrete beams 12 x 12 in. in cross-section and 9 ft. in span were loaded at the ⅓ points with equal loads. Maximum observed steel stress before failure in beams with respective types of reinforcement averaged 34,625 lbs./in.^{2} for plain round bars, 35,762 lbs./in.^{2} for deformed bars and 59,162 lbs./in.^{2} for Isteg bars. Tests on T-beams showed 48% higher efficiency of Isteg bars as to ultimate beam strength. "Pull-out" tests indicated Isteg bars have a higher total value of bond resistance. MS (D-4a) 3

Factors Affecting Red-shortness. FRANK G. NORRIS. *J. Iron Steel Inst.*, Advance Copy No. 10, Oct. 1938, 15 pp. Original research. Samples from 4 open-hearth heats were forged into ½-in. square bars, which were sampled for chemical analysis and tested for red shortness by bending over an anvil while in the red-short range. If the ratio $(MnO + 0.048)/(S + 0.130)$ [in which Mn, S and O are the percentages by weight of Mn, S and total O] is below 3.30, the sample is red short. Samples from previous investigations show that a definite value of this ratio can be established for any one investigation, above which no sample is red short and below which all are. If worked in the red-short range as soon as this temperature range is reached after solidification, a sample with a ratio as high as 6.46 is red short. In the range 6.46-3.30, the cooling conditions affect the red shortness. Independent evidence indicates that the cooling conditions affect the amount of Fe or Mn sulfide. JLG (D-4a) 4 5

The Applicability of Magnesium Alloy (Elektron) Dies (Die Verwendbarkeit von Elektron-Gesenken) B. PREUSS. *Metallwirtschaft*, Vol. 17, Sept. 2, 1938, pp. 932-934. Practical. Briefly discusses the use of Mg alloy dies for the forming of steel automobile fenders. The higher initial cost of these dies is offset by lower handling and tooling costs. The author is rather vague about the life of these dies but indicates that the ease with which these dies can be lined up will help to lead to longer die life. GA (D-4a) 6

4b. Non-Ferrous

Plastic Deformation and Subsequent Recrystallization of Single Crystals of Alpha Brass. M. R. PICKUS & C. H. MATHEWSON (Yale Univ.) *Metals Tech.*, Vol. 5, Dec. 1938, T.P. 989, 21 pp. Original research. Rectangular parallelepipedal specimens were cut from single crystals of α-brass so that they had definite crystallographic relationships. The accuracy of these relationships was determined by X-ray methods. The recrystallization process subsequent to various degrees of plane parallelepipedal compression was investigated. Results indicated that, for intermediate degrees of deformation, single crystals require a higher temperature to effect recrystallization, and recrystallize over a wider range of temperature than does polycrystalline material. For reductions in thickness of 60% or more, the recrystallization temperature appears to be independent of the orientation of the single crystals; in fact, practically no difference was observed between single crystal and polycrystalline specimens. An X-ray study of the orientation changes accompanying deformation was made. The results proved definitely that the orientation (1-10), [112] is significant for single crystals, as with polycrystalline material, and suggests that the development of textures is probably due to similar mechanism. A Comparison of the Extrusion Properties of Some Aluminum Alloys. C. E. PEARSON. *J. Inst. Metals*, Vol. 64, 1938, Advance Copy No. 817, 12 pp. Original research. A comparison was made of the behavior during extrusion of Al and its alloys with 1.5, 2.5 and 5.0% Cu, 1.25% Cu plus 10% Zn, and 5% Zn. The pressures required for extrusion at a fixed rate by the inverted method were determined for different temperatures, and the existence of a simple relationship between pressure and temperature of extrusion was confirmed. Evidence is given to show that the comparison obtained can reasonably be extended to cover rates of extrusion used industrially. The system of flow in billets was determined by observing the distortion of checker-board markings on a split billet. The influence of extrusion temperature on mechanical properties of the alloys was determined. JLG (D-4b) 10

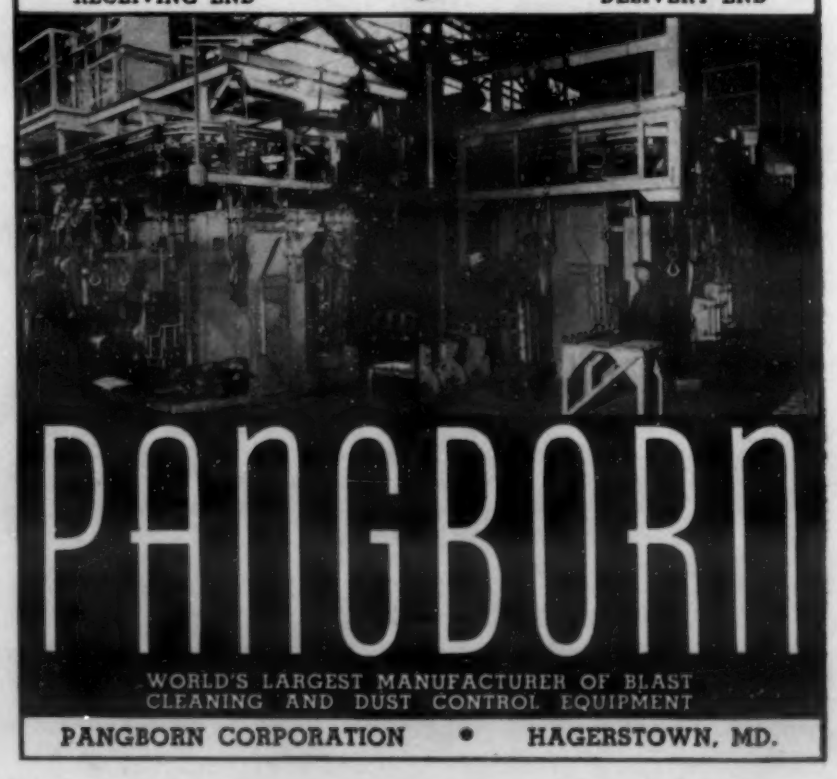
OF ALL AUTOMOBILE CYLINDER BLOCKS ARE NOW BLAST CLEANED BY

ROTOBLASTING



- BUICK
- CADILLAC
- CHEVROLET
- CHRYSLER
- DODGE
- FORD
- LA SALLE
- LINCOLN

- ZEPHYR

SINCE its introduction in Detroit three years ago, 78% of all cylinder blocks are now cleaned by the Pangborn Airless ROTOBLAST Special Cleaning Machine,* which also cleans heads, axle housings, manifolds and many other automotive castings.

At least 95% of all cylinder blocks cleaned by airless blast equipment are ROTOBLASTED by Pangborn equipment. The reason is simple. "Dependable, efficient blasting—24 hours per day!"

Such performance is typical of all Pangborn machines—Rooms, Cabinets, Tables and Barrels. There is a Pangborn blast machine for every requirement, large or small. Write for "Condensed Catalog", showing the complete Pangborn line, fully illustrated, but arranged for stream-lined reading.

5·HEAT TREATMENT AND HEATING

Aging, Annealing, Carburizing, Hardening, Malleableizing, Nitriding, Normalizing, Surface-Hardening and Tempering. Furnaces, Soaking Pits, Refractories, Atmospheres, Fuels and Auxiliaries.

O. E. HARDER, SECTION EDITOR

Low-tungsten Substitutes for High Speed Steel. A. Gorbunov & Ya. Dovgalevskii. *Stal*, Vol. 8, May 1938, pp. 55-60. In Russian. Original research. EI173 (1.10% C, 9.20% Cr, 2.38% W, 0.81% V, 0.25% Si) and EI184 steel (0.98% C, 8.68% Cr, 4.08% W, 1.56% V, 0.62% Si) retain 65% austenite after oil quenching from 1200° C. A single draw at 550° C. decreases the austenite in EI173 to 37% and in EI184 to 29%. A triple draw at 550° C. reduces the residual austenite in each to about 20% with a Rockwell C hardness of 64. Almost complete transformation of the austenite was attained by quenching from 1180-1200° C. in a Pb bath at 600° C. and drawing 3 times at 550° C. for 1 hr. each. Cutting tests showed that these steels stood up better than an 18% W, 4% Cr and 1% V steel. HWR (5)

An Internally Heated Liquid Salt Bath. *Machinery, London*, Vol. 53, Oct. 6, 1938, pp. 14-15. Practical. External heating is inefficient, and leads to excessive pot wear, high stresses in the pot, and non-uniform work, as well as difficulty in control. Internal heating with a.c. current and 2 electrodes overcomes all these disadvantages. There is a minimum of heating energy lost to the external atmosphere, the pot is not subjected to local (external) heat concentration, constant bath circulation is automatic and provides uniform heating, and control is unusually easy. JZB (5)

Atmosphere Controlled Batch Type Furnaces. *Wild-Barfield Heat-Treatment J.*, Vol. 3, Sept. 1938, pp. 23-25. Descriptive. Although atmosphere for a batch type furnace may have been very carefully selected, prepared and controlled, such furnaces are seldom gas-tight and much of the attention to atmosphere may be vitiated by air leakage into the chamber. Furnaces are described that incorporate gas-curtains and door seals claimed to prevent ingress of air and therefore to avoid variations in furnace conditions with each opening of the door. The entire furnace is unusually clean and very compact. FPP (5)

Induction Heating. A. J. G. Smith. *Electrical Rev.*, Vol. 122, June 24, 1938, p. 910. Induction heating is being used successfully for heating of tube, shell and billet ends prior to forging, and end sections of large steel tubes for subsequent swaging operations. Special focus 1-turn coil heats tube end to 1200° C. in about 1 min. With a straight coil, section of a 3 in. diameter billet can be heated uniformly to 1200° C. in 2 min., or 7 in. sq. billet to same temperature in 15 min. About 400 kw.-hrs. are required to heat a ton of steel to forging temperature. Graded temperature can be provided. MS (5)

The Necessity for Control of Steels and Their Heat Treatment. R. J. Brown. *Wild-Barfield Heat-Treatment J.*, Vol. 3, Dec. 1938, pp. 27-30. Interesting discussion of production problems. The main causes of variation in quality of heat-treated automotive products are reviewed, with illustrations of specific instances. Defective heat treatment due to errors in pyrometer control can usually be blamed on failure to check instrument standardization; wherever possible 2 thermocouples should be installed in each furnace, one at the rear for recording and one at the front for control. For the treatment of transmission gears and similar parts, special furnaces, incorporating preheat, soaking and equalizing zones, are recommended. The use of alloy steel is advocated for massive parts where there is strong likelihood that C steel cannot be sufficiently-deeply and uniformly hardened even in water quenching. Several types of defective structures are illustrated, with particular emphasis on the bad effects of primary ferrite network resulting from insufficient temperature or time of heating at hardening temperature. In carburizing, most distortion can be traced to variations in the steel itself, *i. e.* to uneven working of parts of the stock during forging, or to uneven or too coarse grain size. FPP (5a)

The Effect of the Silicon and Aluminum Addition on the Hardenability of Commercial Steels. M. J. R. Morris & H. W. McQuaid (Republic Steel Corp.) *Am. Soc. Metals*, Preprint No. 27, 1938, 27 pp. Original research. The relative effects of small Al and Si additions on the hardenability of a C steel were studied. 3 Six 100-lb. ingots were cast from two 300-lb. heats melted in an arc furnace under an open hearth finishing slag. Al and Si additions were regulated to give the following analysis:

Heat	A	B	C	X	Y	Z
C	0.43	0.45	0.44	0.42	0.42	0.40
Mn	0.95	0.99	0.97	0.95	0.95	0.98
Si	0.005	0.07	0.24	0.01	0.10	0.25
Al	0	0	0	0.046	0.052	0.052
Al_2O_3	0.006	0.003	0.003	0.009	0.009	0.008

4 The ingots were rolled to 1¼ in. diameter bars. Ingots X, Y and Z showed an A.S.T.M. No. 5-6 grain size in the as-rolled condition. A, B and C were somewhat coarser (A.S.T.M. No. 3-5) as-rolled. The low Al heats showed less free ferrite as-rolled. When normalized at 2000° F., all heats were coarse (A.S.T.M. No. 1-3), there being no indication of a variation in Al or Si content. The carburized (McQuaid-Ehn) structure showed the effects of the high Al additions. X, Y, Z were fine grained (A.S.T.M. No. 6-7) while A, B and C were coarse (A.S.T.M. No. 2-3). Grain size 5 was independent of Si content. After the normalizing treatment, specimens were heated to 1500°, 1700° and 1800° F., held 15 min., and quenched in water. After the 1500° F. quench, the 2 high-Si heats, C and Z, were definitely harder than A and X. The fine-grained steel Z hardened as well as the definitely coarse-grained steel C. At 1700° F. heat C was slightly harder than Z. The fine-grained Al-treated Z hardened better than coarse-grained heat A, which in turn showed a better hardenability than the low-Si fine-grained heat X. At 1700° F. Si content was more im- 6 portant than grain size or Al content. At 1800° F. the high Si heats again indicated greater hardenability than the low Si heats. Apparently, difference in hardenability was related more to difference in Si than to grain size or Al. When reheated to 1500° F. from the as-rolled condition, the results differed but slightly from the normalized material. After holding at 1275° F. for 24 hrs. and quenching from 1500° F., there was little difference in the hardenability of the steels tested, the hardenability of all the steels decreasing greatly. Quenching of the steels from 1500° F. in 8% 7 caustic failed to show any marked difference in hardenability between the coarse and fine-grained steels. These experiments indicate that the real causes of variation in properties of this type of steel after quenching are not known. The relation between the physical size of the austenite grain at the time of quenching and hardenability is thought to be less important than low-C austenitic areas, which are present due to non-uniform C solution and diffusion. Al, which expands the ferrite lattice, and Si which contracts it, respectively promote and retard carbide diffusion and 8 thereby affect carbide distribution and hardenability. HLW (5a)

Rolling Mill Instrumentation. J. L. Whitten (Lee Wilson Eng. Co.) *Instruments*, Vol. 11, Dec. 1938, pp. 301-302. Original research. The control of rolling temperatures is the latest development in the field of mill instrumentation. The use of photocells and electron tubes to speed the operation of radiation pyrometer equipment pointed the way to the development of equipment that now can record every variation in temperature along the entire 9 length of the bar, billet or slab. The instrumentation in continuous strip, merchant, blooming, pipe welding, rail, wire rod and seamless tube mills is considered. The author's pioneering work in the dual control application to radiant tube fired furnaces is described. The basic principle is to control the tubes to limit them until the steel has reached its control point, and at that time to switch over automatically from the tube thermocouple to the steel thermocouple and maintain the desired steel temperature, while the tubes continue to fall in temperature during the soaking 10 part of the cycle. Atmosphere control in furnaces of the batch type is desirable. It is predicted, for direct-fired furnaces, that equipment will be available soon that will automatically regulate furnace atmospheres on a definite program to provide different types of atmosphere at different times during the heating cycles. Enlarges Axle Plant. E. F. KENNEY (Bethlehem Steel Co.) *Steel,* Vol. 103, Dec. 5, 1938, pp. 50-52. Describes forging, heat treating, and finishing of axles at Johnstown, Pa., plant of Bethlehem Steel Co. Practices and controls result in precision forgings approaching rough-turned parts in accuracy. All axle blooms are control-cooled to insure slow, uniform cooling. They are heated in a pusher-type furnace with 580 sq. ft. of hearth area. Burners are arranged across front of furnace and flames pass over steel to flue in back. Heated blooms are rolled to desired diameter and immediately forged. Forging is placed on a cooling bed, and when still at a dull red heat, is straightened in a special press. Heat treatment or slow cooling then follows. Driving axles and special items are forged directly from heated bloom without rolling. Special furnace with 252 sq. ft. hearth area is used for these products. Practically all alloy steel and many special forgings are heat treated. Alloy steels and high-C steels are always charged on a cold hearth. There are 2 heat-treating furnaces, each with 443 sq. ft. hearth area and rows of burners along each side, arranged so flame does not directly contact steel. Treatment of charge considers both grain size and physical properties desired. In annealing, forgings are heated to desired temperature, soaked, cooled in furnace to well below critical point, and placed on cooling bed. In normalizing, forgings are heated to desired temperature, soaked, pulled from furnace and cooled in air almost to room temperature, heated slowly to drawing temperature, soaked, cooled in furnace and placed on cooling bed. Quenching procedure is same as used in normalizing, except that forgings are quenched in H_2O or oil when first removed from furnace and are immediately recharged to drawing furnace. Forgings are soaked at rate of 1 hr. per 1 in. diameter. Proper flame is used to prevent excessive scaling. All furnaces are heated with coke-oven gas and have pyrometer control. MS (5a)

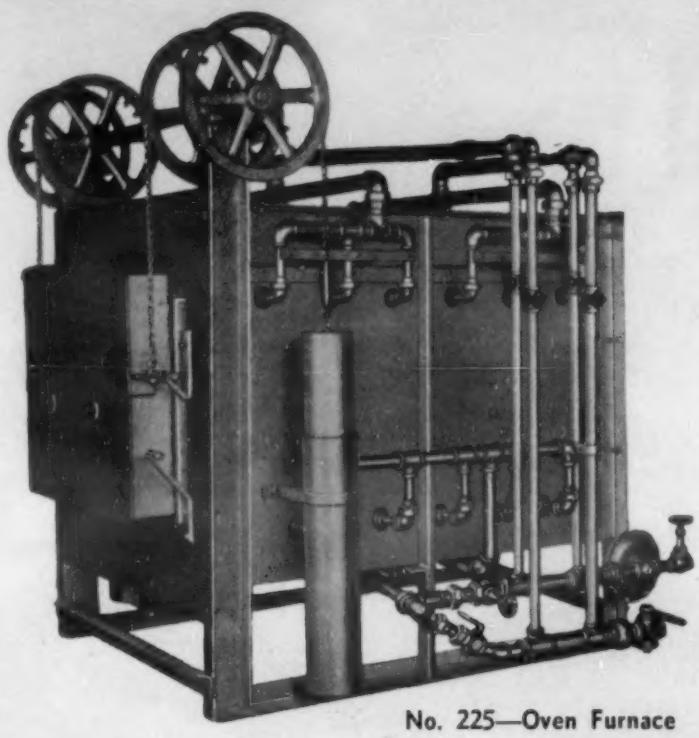
The Softening Rate of a Steel when Tempered from Different Initial Structures. E. H. ENGEL (Carnegie-Illinois Steel Corp.) *Am. Soc. Metals,* Preprint No. I, 1938, 16 pp. Original research. Specimens of a steel (0.94% C, 0.40% Mn) were heat treated to 4 structures: Martensite, bainite (dark etching acicular product of austenite transformation at constant temperature), fine nodular pearlite and coarse pearlite. The treated specimens were tempered for a period ranging from 2 sec. to 22 hrs. at temperatures of 600°, 900°, 1050,° 1200° and 1300° F., and the hardness and microstructures determined. The rate of softening during tempering of the steel was dependent on the initial structure. The finer the state of carbide dispersion before tempering, the faster was the decrease in Brinell hardness during tempering. In the order of their softening rate, the structures were martensite, bainite, fine pearlite and coarse pearlite—the last being the slowest. At the high tempering temperatures the 4 structures approached a common hardness which decreased more and more slowly with increased time at temperature. The study indicates that under appropriate tempering conditions the martensitic surface region of a section of quenched steel that failed to harden all the way through may be made softer than the relatively soft (pearlitic) core that did not harden on quenching. The U-shaped curve representing hardness distribution in a quenched cylinder can be flattened out and even inverted by a selection of time-temperature conditions of tempering. When a well-spheroidized uniform structure is desired on tempering, an initial structure of coarse pearlite should be avoided. HLW (5a)

The Heat-brittleness of Steel. IWAO HAGIWARA. *Tetsu-to-Hagane,* Vol. 24, Jan. 25, 1938, pp. 13-24. In Japanese. The relation between the heat-brittleness and the heat-treatment of steel are studied. Specimens of basic open hearth steel containing 0.2 and 0.3% C and Ni-Cr steel containing 3.4% Ni, 0.7% Cr and 0.28% C, which were cooled from 900° and 850° in various mediums, such as water, oil, air, etc., were subjected to tensile testing at various temperatures between 20° and 800° C. to determine the strength and the reduction of area. The precipitation of cementite dissolved in α-Fe below A_1 causes a brittleness different from the familiar temper-brittleness that occurs at lower temperature. The former brittleness appears only when cementite separates in pearlite form but not in sorbitic. The temper-brittleness range is independent of the cooling rates of specimens so long as martensite is not formed. The so-called "secondary brittleness" (at 500°-700° C.) appears in coarse-grained specimens. The same type of study was made of Ni-Cr steels containing various amounts of C, Ni, Cr, Mo, Mn and Si. All these elements, particularly C and Mn, promote secondary brittleness. (2) Cr and Mn shift this type of brittleness to lower temperatures. (3) As the content of Mn and Si increases, a new brittleness appears below the critical point. TS (5a)

Scale Free Hardening of Screw Products. *Iron Age,* Vol. 142, Aug. 25, 1938, pp. 34-35. Practical description of a heat treating furnace. Parts varying from ¼ in. in diameter by ¾ in. long to ⅞ in. in diameter to 12 in. long are uniformly hardened in this furnace without scaling. Pickling or rolling of threads after hardening is eliminated. Maximum production is obtained by placing products of predetermined weight in the furnace at exact intervals. VSP (5a)

MAKING MOLECULES
As Real As RASPBERRIES



Molecules are no mystery to the Kemp Constant Analysis Monitor. The twin installation shown above provides a sensitive, practically instantaneous electrical nervous system for a pair of Kemp 15,000 c. f. h. Atmos-Gas Producers in one of the largest and most modern sheet mills in the world.

Atmos-Gas that goes to these annealing furnaces is *right* and *stays right*, for by means of its constant sampling and constant analysis of the product gas, the C. A. Monitor automatically compensates for the uncontrollable variables the instant they effect the composition of the Atmos-Gas.

The C. A. Monitor operates Kemp Atmos-Gas Producers (and any other controllable atmosphere generator) of all capacities from 1,000 to 15,000 c. f. h.

Special, detailed bulletins on the C. A. Monitor and Atmos-Gas Equipment are now available. Address The **C. M. Kemp Mfg. Co., 405 East Oliver St., Baltimore, Md.**

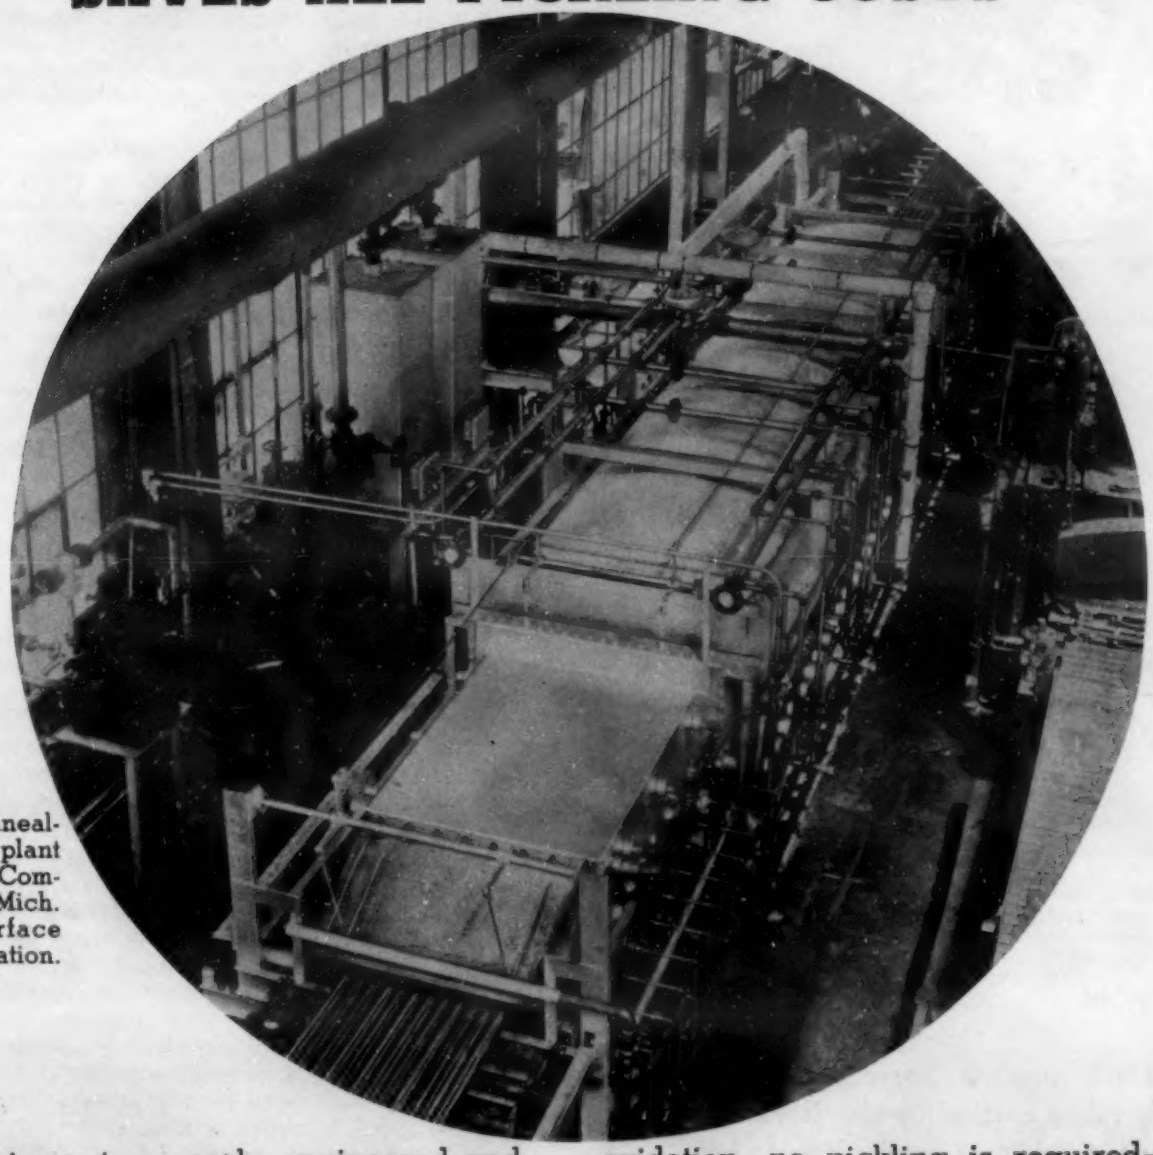
Autogenous Hardening of Cast Iron and Malleable Castings (Autogenes Härten von Gusseisen und Temperguss) G. KRITZLER & F. ROLL. *Giesserei,* Vol. 25, Dec. 2, 1938, pp. 609-617. Experiments have shown that blackheart malleable castings can be made by autogenous surface hardening (flame hardening), more suitable for certain purposes. The surface can be made pearlitic, sorbitic, martensitic and cementitic to martensitic according to the heat-treatment applied; the hardness can be varied between 200 and 600 Brinell. The higher the temper resistance of the material must be, the more the hardening must tend to produce a cementite structure. Quenching in air, oil and water is applied according to the desired hardness. The flame must have an acetylene excess to avoid decarburization at the marginal zones; the most favorable structural condition is obtained if the surface has not been decarburized by the annealing process. A martensitic structure loses its hardness at 100° C., while a cementitic structure is stable up to 280° C. Crankshafts so hardened have shown no measurable wear after 56,000 miles. The fatigue strength is very good, as correctly hardened surfaces maintain a tough core of ferrite and temper C. Fatigue fracture occurs in such hardened parts much less than in hardened steel alloys, as stress peaks are absorbed in the temper C. Ha (5a)

The Effect of Type of Cold Deformation on the Recrystallization Properties of Armco Iron. HERMAN F. KAISER & HOWARD F. TAYLOR (Naval Res. Lab.) *Am. Soc. Metals,* Preprint No. 17, 1938, 38 pp. Research. The relation between the amounts and kinds of cold deformation required to produce recrystallization in Armco Fe when annealed at various temperatures was determined for 2 lots of Fe. Deformations studied were: Torsion, elongation in tension and rolling. Prior to cold working, all specimens were given a uniform initial grain size by heating back and forth through A_3 (875°-923° C.). Critical values were arbitrarily chosen as mean values of 2 deformations, between which there occurred a marked change in grain size. After deformation, specimens were annealed for about 3 hrs. at temperatures ranging from 300° to 875° C. In the case of samples manifesting coarse grains after deformation and annealing, many small grains were located in the boundaries of the larger grains. Results are summarized in recrystallization diagrams. It is possible to relate the critical degree of deformation for an annealing temperature for the 3 types of cold deformation by expressing the degree of deformation in terms of octahedral shear. Studies on the effect of annealing time established that the critical degree of reduction decreased as the length of annealing time increased. HLW (5a)



Furnace Stress-relieves Vessels that Are Longer than Itself. *Steel,* Vol. 103, Nov. 14, 1938, p. 67. Descriptive. Furnace at Birmingham, Ala., plant of Chicago Bridge & Iron Co., is 80 ft. long inside, 14 ft. wide and 17½ ft. high to crown of arch. It has a standard gage track. Furnace bottom consists of a specially-constructed 28-wheel car 83 ft. long, floored with 4½ in. of insulating concrete and 13½ in. of insulating fire-brick. Meehanite supports carry vessel. Sides of arch of furnace have 9 in. of insulating fire-brick. Doors at both ends are lined with 10 in. of insulating concrete. Vessels longer than furnace are handled in 2 operations, with an end extending out of furnace each time. A temporary brick inclosure is built around vessel where it leaves end of furnace, sealing it. By-product coke-oven gas is burned in 64 low-pressure type burners, divided equally between top and bottom of furnace. Burners are divided into 12 zones with balanced valve regulator and dial-type recording pyrometer that actuates a 4-position controller on air-supply pipe for each. MS (5a)

Rapid Malleableizing (Ueber Schnelltemperguss) E. PIWOWARSKY. *Giesserei,* Vol. 25, Nov. 18, 1938, pp. 584-594. Review. American and European malleableizing practice is surveyed, and effect of temperature and chemical composition on velocity of malleableizing and on properties of malleable castings are illustrated by many diagrams and micrographs. Increasing annealing temperature results in increased carbide disintegration, which is accelerated by previous quenching. The formation of ferrite has a relation to the carbide disintegration; a periodic process exists, involving carbide disintegration with subsequent solution of C. A malleable casting containing more or less ferrite can be obtained by correct timing of the interruption of the annealing process. Recently, experiments were made in malleableizing with high frequency current, which resulted in a somewhat finer grain and temper C; the Fe used had the composition C 3.20%, Mn 0.35%, Si 0.55%, P 0.08%, S 0.020%. 19 references. Materials used, properties they must have, design, composition, practices in different countries and methods of laying and joining bricks are described. Ha (5a)

OPEN-FIRED *Gas* FURNACE

SAVES ALL PICKLING COSTS

Open-fired, bright annealing GAS furnace in plant of the Mueller Brass Company, Port Huron, Mich. Photo courtesy Surface Combustion Corporation.

Modern GAS equipment, properly engineered and installed, is setting new records of efficiency and economy for plants of all types and sizes.

In the furnace illustrated, for example, up-to-date GAS applications provide an ideal bright annealing atmosphere for copper, through the use of open-fired burners. Since the annealed tubing is free from oxidation, no pickling is required—and the plant saves an average pickling cost of $1.22 per ton on its product. Actually the furnace paid for itself in less than a year.

Investigate what modern GAS equipment can do to improve the quality of your products, to reduce costs and to bring you extra profits!

PERFECT

For heat treating high speed steel

JUTHE GAS FURNACE

Model HG-2 Furnace with Inspirator, Foot Treadle Door Lift, and Dehydrating Cylinders for Atmospheric Control. Perfect heat distribution guarantees uniform results. Is equipped with silicon carbide muffle 12"x18"x8".

Any heat treating process between 1900 and 2500°F. is easily taken care of by the JUTHE High Speed Gas Furnace. Designed particularly to handle the high temperature operation required by high speed steels, this furnace takes even the toughest job in its stride, without straining, *consuming as little fuel as is scientifically possible.*

Equally well-fitted, for tool room or production line, the JUTHE furnace permits closer limits of accuracy . . . increases quality production . . . betters working conditions in the heat treating department. Like all JUTHE furnaces, the High Speed Furnace has "AMERICAN" Atmospheric Control which prevents scaling, burning, and decarburization while reducing dimensional change and grain growth.

There's a JUTHE furnace for every industrial requirement. Write for details.

Investigation of Normal and Accelerated Aging by Thermoelectric Studies (Beitrag zur Frage der Kalt- und Warmaushärtung auf Grund thermoelektrischer Untersuchungen) A. DURER & W. KÖSTER. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 311-319. Experimental. "Normal" or "low temperature aging" is described as the agglomeration of atoms of the second phase in a supersaturated solid solution without the formation of a new crystal lattice. "Accelerated" or "high temperature aging" is considered as true precipitation of a new lattice type from a supersaturated solid solution. These processes were followed in an alloy of Al with 4% Mg and 8% Zn by measurement of the electrical resistance and thermal e.m.f. of the alloy. By annealing for various lengths of time at different temperatures, 4 classifications can be made: (1) Increasing normal aging, (2) decreasing normal aging, (3) increasing accelerated aging, (4) coagulation of the precipitated phase. These can be distinguished by breaks in the curves of the thermal e.m.f. against temperature. The maximum possible normal aging was determined for each temperature and a limiting temperature established, dependent upon the time at temperature below which only normal aging could be realized. Heating for short periods of time destroys the effects of normal aging, but such treatment does not eliminate subsequent accelerated aging. This treatment does change the rate of accelerated aging, however, and the 2 processes cannot be regarded as independent of each other. GD (5b)

Age-hardening of High Coercive Force Iron-nickel-aluminum Alloy. A. A. KUZNETSOV. *Metallurg,* Vol. 13, July/Aug. 1938, pp. 59-64. In Russian. Original research. Structural aging of an alloy containing 27% Ni and 15% Al was studied at 20°, 100°, 300°, 400° and 500° C. The coercive force rises and reaches a maximum after 20-25 days at 20°, 35-45 hrs. at 100°, 11-15 hrs. at 300°, 2-3 hrs. at 400° and 1 hr. at 500° C. After reaching the maximum, the coercive force drops somewhat and becomes nearly constant. The drop is nearly the same (6-7%) in all cases and is independent of the temperature. The temperature affects only the time of stabilization. Thus, at 20° C. structural stabilization is reached after 100-120 days, at 100° C. after 65-70 hrs., and at 300°-500° C. after 18-24 hrs. BZK (5b)

The Aging of Aluminum-magnesium-zinc Alloys and Recovery from Low Temperature Aging (Ueber die Aushärtung von Aluminium-Magnesium-Zink-Legierungen und die Rückbildung der Kaltaushärtung) W. KÖSTER & K. KAM. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 320-322. Experimental. Aging curves, showing the effect of heat treatment on the Brinell hardness, and tensile properties of a number of Al-rich alloys in the Al-Mg-Zn system were determined. The values obtained depended more upon the type of heat treatment than upon the phases participating in the aging reaction. The considerable low-temperature aging effected by holding the quenched alloy at 20° C. for 9 days could be almost completely eliminated by annealing at higher temperatures, about 200° C., for less than a minute. GD (5b)

Heat Treatment of Non-ferrous Metals and Alloys. RALPH D. HAWKINS (Bridgeport Gas Light Co.) *Heat Treating Forging,* Vol. 24, Nov. 1938, pp. 569-574, 577. Report of Non-Ferrous Metals Committee, Industrial Gas Section, Amer. Gas Assoc. Summary of the operations through which an ingot of Cu or its alloys may pass before reaching the finished stage. Describes major operations in sheet, tube, wire and rod mills and in fabricating plants, with chief attention to their requirements relative to fuel and furnace equipment as far as generally accepted practice is concerned. Points out general trends. MS (5b)

The Investigation of Aging Phenomena. Part I. The Influence of Al, Fe, Co and Cr on the Aging of Corson Alloy. K. IWASE, M. OKAMOTO, A. ADATI & I. SUZUKI. *Nippon Kinzoku Gakkai-Si,* Vol. 2, Sept. 1938, pp. 419-430. In Japanese. Original research. In order to eliminate the maximum in the hardness-time curve of Corson alloy aged at 500° C., additions were made of Al, Fe, Co and Cr, the amount for Al being 1-10% and for others less than 5% each. Although the object can be attained by adding Al alone, further improvement was made by additions of Fe and Co, besides Al. Cr was not as effective as Fe and Co. NS (5b)

A Dialogue on the Embrittlement of Cu. T. S. FULLER. *Gen. Elec. Rev.,* Vol. 41, July 1938, pp. 312-313. Review, in socratic dialogue, of the problem of O in Cu, a factor still causing difficulties for the engineer. Tough pitch Cu with 0.03-0.04% O can be embrittled when subjected to reducing atmospheres, such as H_2 and CO. Not only is the O present as Cu_2O reduced, but the O dissolved in the Cu is also affected. The only remedy is the substitution of "O-free Cu" if the material is to be heated in a reducing atmosphere. FHC (5b)

E. V. DAVID, SECTION EDITOR

Silver Alloy Brazing of Tubes in High Pressure Boilers. A. W. WEIR & H. M. WEBBER. *Welding J., N. Y.,* Vol. 17, Oct. 1938, pp. 50-56. Practical. The problem of brazing of Cu tubes into steel tube sheets presented itself as a result of frequent failure of mechanical joints with consequent leakage. Fire tube boilers used for heating passenger cars and for hot water were formerly expanded into tube sheet by means of steel ferrule, but differential expansion of Cu tubes and steel sheet along with vibration opened up the joints. Welding of the tubes to the sheet by several methods has been investigated, but so far has not produced satisfactory results. The Ag alloy brazing process, however, using the furnace brazing method and joining all tubes at one time appeared to be feasible. Consideration had to be given to furnace atmosphere because of the use of P-deoxidized Cu, which could not be considered as completely and consistently deoxidized. Tests were made of 3 furnace atmosphere mixtures as follows:

	No. 1	No. 2	No. 3
CO_2	10.6	0	10.6
O_2	0	0.2–0.4	0.2
CO	0.2	0	0
H_2	0.3	0	0
N_2	88.9	99.8–99.6	89.2

Use of No. 1 gas resulted in embrittlement on outer surface of Cu tube and complete embrittlement on tough pitch Cu, while No. 2 and 3 showed no embrittling effect, owing to slightly oxidizing character of atmosphere. Due to the latter the flux had to be depended upon to prevent an oxidized surface into which the Ag alloy was to flow during furnace treatment. Production test was made on assembled tube bundle made up with mechanically and chemically cleaned Cu tubes set into tube sheet and placed on pedestal of a bell type furnace. The tubes were in vertical position during furnace cycle of 4½ hrs., 2 hrs. to heat to 1240° F. The tube sheets were prepared by applying flux to all tube holes and inserting a ring of Ag brazing alloy; Cu tubes were then inserted and flux applied on ends. Examination of the joints indicated that jointing was perfect, and severe steaming tests made on the completed boiler showed that exceptional strength and resistance to rapid temperature changes had been attained. The reduction of maintenance costs will justify the furnace brazing method of producing the boiler. Illustrations for various phases of production, and micrographs of the bond formed between the steel and Cu tube are given. WB (6)

The Influence of Residual Stress on the Strength of Welded Seams. J. P. DEN HARTOG & O. E. RODGERS (Harvard Univ.) *Welding J., N. Y.,* Vol. 17, Nov. 1938, Suppl. pp. 1-3. A method is described for producing an internal stress distribution in plates similar to that found in welded plates, without changing the metallurgical structure of the plates. By this method the effect of internal stress on strength properties can be evaluated without any disturbing effect from the metallurgical changes produced by the welding process. The plates were subjected to destructive tensile tests in a direction parallel as well as perpendicular to the direction of the internal stresses. The cracks observed in welded structures of ductile boiler plate subjected to slowly varying stress are due, not to internal stresses, but to metallurgical modifications of the material. Stress annealing is therefore not necessary for structures that are subjected to unvarying or slowly varying stresses. CEJ (6)

Brazing Alloys. P. MABB. *Machinery, London,* Vol. 53, Oct. 6, 1938, pp. 17-18. Practical. Strength and melting point of the brass brazing alloys are a function of composition; latter can vary between 880° and 1050° C. The addition of AgCu increases the ductility, hardness and strength; AgZn increases the hardness and corrosion resistance. The Ag is usually added to the brasses at the expense of the Cu, giving alloys with melting points from 305° to 1045° C. Sn tends to reduce the ductility. A new P-deoxidized Ag-Cu alloy has been introduced. The Ag solders are preferable from the standpoints of fluidity, penetration, corrosion resistance, electrical conductivity, malleability and high strength. Borax is the most widely used flux. JZB (6)

The Metallurgical Aspects of Resistance Welding Electrodes. R. H. HARRINGTON (Gen. Elec. Co.) *Welding J., N. Y.,* Vol. 17, Oct. 1938, Suppl. pp. 18-22. Survey of history, present alloys in use and future metallurgical development. The early use of pure Cu, work hardened as in cold drawn bar stock, was excellent for electrical conductivity but proved to be costly to maintain as electrode material, because of ease of deformation. The next step in evolution was the use of Cu with 1% Cd, which could be work hardened to a greater extent than Cu and possessed sufficient conductivity to be useful as electrodes. With increase in resistance welding applications, the latter were grouped into 4 classes wherein specific applications of the best electrode alloy could be made for each class: (1) Plain C steels, (2) stainless (or alloy) steels, (3) non-ferrous alloys such as brasses and bronzes and (4) Cu. Each classification is considered in detail, and their own specific requirements are discussed. The electrode material for these welds cover a wide range from special bronzes, pressed powder mixtures of Cu, Ag and W to the use of pure W. Some of the Cu alloy compositions are tabulated with mechanical, physical and electrical properties as well as some of the Cu-W, W-Ag, W powder mixtures for which hardness values and electrical conductivity values are shown. Desirable properties of electrode materials are enumerated as: (1) suitable electrical conductivity, (2) high proportional limit, (3) maintenance of physical properties at as high a service temperature as possible, and (4) the "X-property," probably contact surface resistance. The future field for electrode metallurgy is considered to be in the precipitation hardenable alloys. WB (6)

Electrode Alloys for Welding Small Contacts. E. E. HALLS. *Aluminium & Non-Ferrous Rev.,* Vol. 3, Sept. 1938, pp. 391-392. Practical. Electrical contact metals should be non-tarnishing, non-arcing, abrasion resistant and have high conductivity. Flat discs and conical points, which can be riveted or welded to the holder, are used. Welding has many advantages. Contacts can be produced and welded on automatic machines. Cu as welding material fulfills many requirements but tarnishes, oxidizes and deforms under pressure. W has advantages but is low in electrical and thermal conductivity. A combination of both is used as a sintered alloy, containing 40% W and 60% Cu. Cu is also used with additions of 1% Cd, or 1% Cd plus 1% Ag; the additions increase the hardness. Age-hardening alloys for welding contact points contain *e.g.:* 0.48-0.53% Zn, 0.27-0.31% Cr, 0.19-0.21% Be, balance Cu. These alloys are not much better than Cu with regard to tarnishing and arcing, but are superior as far as wear and deformation are concerned. The ideal material has not yet been developed. RPS (6)

Bi-metal Construction of High Temperature Steel Valves. E. R. SEABLOOM (Crane Co.) *Welding J., N. Y.,* Vol. 17, Nov. 1938, pp. 28-36. Descriptive. Valve manufacturers are constantly confronted with metallurgical problems which the ever-increasing operating pressures and temperatures impose upon materials that enter into valve construction. In the oil industry, cracking stills are now in use with pressures at 3,000 lbs./in.^{2} and temperatures of 1200° F. The general practice, at least by the author's company, is to employ deposited surfaces on disks and seats of all valves used on steam pressures above 750° F. A Co-Cr-W alloy is one of the most popular deposited surfacing materials, because it possesses excellent resistance to wear, seizure and abrasion at high temperatures. It also withstands certain types of corrosion well and is fairly resistant to erosion. Manually operated oxy-acetylene torch is the usual process used. Preheating and slow cooling is the usual practice. CEJ (6)

Resistance Welding in the Automotive Industry. J. A. WIEGER (P. R. Mallory & Co.) *Ind. & Welding,* Vol. 2, Dec. 1938, pp. 54-60. Review. Resistance welding has steadily and rapidly improved since it was first put into operation. Automatic operation is noticeably gaining as operator fatigue is greatly reduced, thereby maintaining production at a high level. The results are: Faster operation, lower current consumption, longer electrode life and better, smoother and more uniform welds. CEJ (6)

FREE ARCOS WALL CHART

For Cr. & Cr.-Ni. Alloys-Sheet, Plate, Castings.

HERE is a Wall Chart packed full of useful information for the welding fabricators of stainless steel and special alloy metals. Its cross-reference of accurate data eliminates hours of chasing down information. The answers to your questions are always at your finger-tips.

Included are Iron and Steel Institute type numbers, corresponding analyses, popular names, company trade names of manufacturers of sheets, plates and castings. Twenty-eight grades of Arcos alloy electrodes are listed and their weld metal analyses given—also micrographs of typical weld structures, as well as other valuable and handy information.

This attractive silver and black Wall Chart is indispensable for the offices of engineers, metallurgists, and superintendents. Write for your free Arcos Chart today on your company letterhead. The supply is limited.

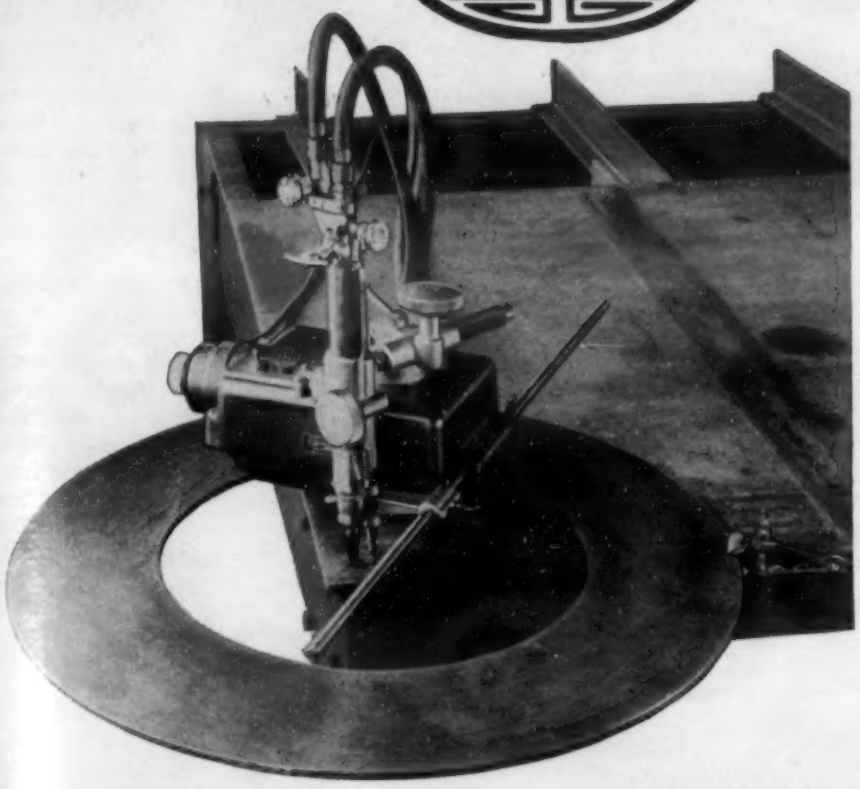
PIONEER OF STAINLESS STEEL ELECTRODES IN U. S.

Low-temperature Silver Brazing Alloys. H. A. FOLGNER (Handy & Harmon) *Iron Age,* Vol. 142, Oct. 13, 1938, pp. 161-162, 164-169, 290. Practical discussion of the use of low temperature Ag brazing alloys for various types of metal joining. One
1 of the alloys used is known as Sil-Fos, composed of 15% Ag, 80% Cu and 5% P. It is used for joining non-ferrous metals, principally Cu, brass and bronze. It has a melting point of 1185° F. and is free-flowing at 1300° F. Another alloy, known as Easy-
— Flo, begins to melt at 1160° F. and is usually free-flowing at 1175° F. It has Ag content of about 50%, balance Cu, Zn and Cd, and may be used for joining most of the ferrous metals. New development of flux to be used with these brazing alloys is known
2 as Handy Flux. It begins to fuse at 800° F., and at 1100° F. is a thin active fluid that insures thorough wetting of joint surface by Ag brazing alloy. The applications of these brazing alloys in various fields are considered, such as: In the manufacture of air conditioning and refrigerating parts, assembling unit heaters, elec-
— trical industry, etc. Very little Ag brazing alloy is required, regardless of the nature of the joint to be made. Ag brazing alloy has tremendous possibilities for wider industrial use. . . VSP (6)

Welding Eliminates the Hot Box. W. C. SWIFT (Compressed
3 Ind. Gases, Inc.) *Ind. & Welding,* Vol. 3, Jan. 1939, pp. 40-42. Practical. Hot boxes can be caused by the crown brass in locomotive drive box becoming loose. Phosphor bronzes, high in Pb, can be firmly welded to wrought and cast steel with the C arc.
— By changing the drive box pattern to leave only about ⅜ in. to ½ in. space between the surface of the axle journal and the inside surface of the drive box, and then welding a high phosphor-leaded bronze to the inside of the drive box surface, a successful
4 design has been produced. The Southern Pacific Road and The Great Northern have successfully used this or similar repairs and construction. CEJ (6)

Some Aspects of Modern Brazing Practice. H. J. MILLER. *Metal Treatment,* Vol. 5, Summer 1938, pp. 64-70. Up-to-date
— review. Brasses with 60 or 54% Zn are used for brazing Cu and alloys with melting points above 950° C.; those with 50% Zn and the Ag solders for lower melting point alloys. Brass with 63% Zn has been used for Cu, but temperature and time of heat-
5 ing need careful control to restrict thinning of the Cu by solution in the brass. The Cu-P and Cu-Ag-P alloys have good self-fluxing properties, and the latter is being used for resistance brazing with C electrodes. 15 references. JCC (6)

Code Requirements in the Shipbuilding Industry. *Ind. &*
— *Welding,* Vol. 3, Jan. 1939, pp. 24-26. The codes, briefed and tabulated, include material from Lloyd's Rules and Regulations for Ship Construction and Repair, the American Welding Society's Marine Code for Welding and Gas Cutting and the American
6 Bureau of Shipping Requirements for Ship Construction and Repair. This résumé is concerned primarily with the codes as far as hull and general structural work is concerned. No great disagreement either in principle or in practice is revealed. CEJ (6)



— **The Determination of Internal Stresses from the Temperature History of a Butt-welded Plate.** O. E. RODGERS & J. R. FETCHER (Harvard Univ.) *Welding J., N. Y.,* Vol. 17, Nov. 1938, Suppl. pp. 4-7. The internal stress distribution to be expected in 2 plates,
7 butt-welded together by the thermit process, is calculated from the experimental record of the variation with time of the temperature over the surface of the plate. This stress distribution is found to be in good agreement with the internal stresses measured by the relaxation method. CEJ (6)

Welding High-pressure Piping, Essex Generating Station. H.
8 WEISBERG (Pub. Serv. Elec. & Gas Co.) *Welding J., N. Y.,* Vol. 17, Nov. 1938, pp. 3-9. Practical. Paper describes the welding that was done in connection with the piping and, principally, the
— field welding of the high-pressure, high-temperature steam and water piping for the new unit of Pub. Serv. Elec. & Gas Co., N. J., the Essex Generating Station. This unit consists of a 50,000 kw. superposed turbine generator and two 600,000 lbs./hr. boilers oper-
9 ating with steam conditions of 1250 lbs., 950° F. at the turbine throttle. Preheating was found essential for the welding of C-Mo steel pipe. The cooling of the weld before completion and stress relieving often resulted in cracks. It was specified, therefore, that
— the pipe at the weld be preheated to a minimum of 400 F. and held at this temperature until the weld was stress relieved. The heat was generated in the pipe wall by electrical induction, the heating element being left in place during welding. The heating element was made up by wrapping the pipe on each side of the weld with several turns of heavy, bare Cu wire connected to a
10 transformer delivering 20-40 volts at 60 cycles. Asbestos paper was used to insulate the wire from the pipe. Hand arc welding, using qualified welders under an insurance company inspection service, was used. The day may come when practically all power plant pressure joints will be made by welding. CEJ (6a)

You can cut circles at plate edges with the AIRCO No. 10 RADIAGRAPH

CUT them at the *extreme* edge of the plate or as near the edge as may be required — this little motor-driven gas cutting machine does it readily. At the left you see the No. 10 RADIAGRAPH set up for cutting a 2″ circle right close to a plate corner. Below, is the set-up for cutting a 14″ circle at the extreme edge. The support ring shown clamped to the plate, on which the machine travels, is needed only for circles under 15½″ diameter. Where needed, such a ring can be cut from ¼″ plate with the machine itself.

And here is the complete range of gas cutting you can do with the No. 10 RADIAGRAPH.

- Cut circles from 2″ to 85″ in diameter, with either square or beveled edges.
  (No extra attachment required for cutting bevels)
- Cut arcs up to 42½″ radius with either square or beveled edges.
- Cut straight lines of any length with either square or beveled edges.
- Cut irregular outlines, to a limited degree, by manual operation of the torch adjusting arm.

At this low price the No. 10 RADIAGRAPH is the biggest value ever offered in a gas cutting machine. Price includes the machine proper, torch adjusting unit, standard AIRCO machine cutting torch, radius rod and center point for circle cutting, and one length of track for straight line cutting. Full details in the No. 10 RADIAGRAPH Bulletin. Write for a copy — today.

What more can you ask in a brazed joint!

STRENGTH

Sil-Fos and Easy-Flo brazed joints are stronger than the metals joined. Under breaking tests the metals joined give way—not the joints.

DUCTILITY

Bend, twist, hammer and pound Sil-Fos or Easy-Flo joints — the silver in them makes ductile joints that are practically indestructible.

LEAK-TIGHTNESS

Turn on pressure—the metal will let go without a leak or break in the joint. Free-flowing Sil-Fos and Easy-Flo penetrate to every crevice — make leak-tight joints.

LOW COST

Thin films of Sil-Fos or Easy-Flo make the best joints. Fast application, less labor, gas and finishing expense contribute further to low costs.

If you are not using Sil-Fos or Easy-Flo, write for Bulletins MA-5, 9 and 10.

Weldability of Medium Carbon Steel. R. W. EMERSON (Westinghouse Elec. Mfg. Co.) *Welding J., N. Y.*, Vol. 17, Oct. 1938, Suppl. pp. 7-17. Original research, reported for steels of 0.30-0.50% C. Determinations of the thermal cycle for the heat-affected base metal under various conditions of welding were first made. The details of thermocouple size, temperature recording, etc., are not given, but a number of temperature-time curves for plates of varying thickness and for the 1st, 2nd and 3rd pass with and without preheat of multiple pass welds are shown. The curves present a clear picture of the effects of increasing plate size (mass) in inducing a rapid quench of the heat-affected area. The multiple pass thermal history indicates progressively lower rates of cooling as the number of passes increases, while the use of preheat brings about a remarkable uniformity in cooling rate for the 3 passes of the multiple pass weld. In order to define the hardenability of a series of steels ranging from 0.30 to 0.50% C with grain sizes of from 4-7 to 6-8, the author departs from the usual method of single bead welding on flat plates. Use is made of a 3-3½ in. round bar 10 in. long, and the welding beads are laid on the surface of the bar along the 10 in. length under various controlled conditions of welding in single bead for different electrode sizes and currents, in 2 and 3 pass welds, pre-heating, etc. The Vickers hardness values of the heat-affected zones are shown in curves, which bring out the beneficial effects of the multiple pass weld and preheat for the single pass weld. Macroscopic examination of the welds indicated that where preheat was used, the heat-affected zone had a wider extent and a gradual transition of macrostructure, whereas a steep temperature gradient established in welding initially-cold metal produced the most sharply defined heat-affected zone. A fine grain steel should show a narrower heat-affected zone and differences in other properties than a coarse grained steel, but results so far obtained are inconclusive owing to insufficient grain size contrast and extremely narrow range of heat-affected zone. The micros presented also reveal that striking differences in the heat-affected zone caused by differences in grain size are lacking. A detailed and helpful discussion accompanies the micros of heat-affected zone shown for various steels and welding conditions. Precautions include the choosing of electrode size suitable for thickness of plate to be welded, and the proper use of preheat and multiple pass welding in order to have austenite decomposition products other than martensite in the heat-affected zone.
Wb (6a)

An Investigation of the Cored Electrode for the Arc Welding of Steel. I. The Effects of Elements in the Core on the Soundness of Deposited Metal. H. SEKIGUCHI. *Nippon Kinzoku Gakkai-Si*, Vol. 2, Sept. 1938, pp. 444-462. In Japanese. Original research. Steel core-rods containing one of the elements Co, Mo, Cu, Ni, W, V, Si, Ti, Al, C, Mn or Cr, were made, on which a flux consisting of 70% CaF_2 and 30% $Ca(OH)_2$ was coated. With these electrodes, single V butt joints of mild steel were made, and soundness of the welded joint was examined by X-ray and microscopic methods; the apparent specific gravity of the deposited metal was also measured. As the content of deoxidizer, such as V, Mn, Si, Ti, Al or C, increases in the core-rod of a coated electrode, the quantity of blow holes in the deposited metal decreases, but the non-metallic inclusion content increases except C. In the case of coated electrodes containing Cr or Mn many holes on the surface of beads appeared. **II. The Effect of Deoxidizers in the Electrode-core-rod on the Apparent Specific Gravity and Mechanical Properties of Deposited Metals.** *Ibid.*, Oct. 1938, pp. 483-494. With electrodes of many steel-core-rods containing 3 deoxidizers, Mn, Si and Al, in different proportions, on which was coated the same flux as described above, single V butt joints of mild steel were made. The use of electrodes containing a higher quantity of deoxidizers in the core-rod results in fewer blow holes and oxide inclusions in the deposited metals and much better mechanical properties.
NS (6a)

Arc Welding in the Automotive Industry. H. D. DOUD (Gen. Elec. Co.) *Ind. & Welding*, Vol. 11, Oct. 1938, pp. 21-24, 70-72. Although but a small fraction of the metal used in an automobile is deposited by means of arc welding, those small weld-beads do the work that would require many pounds of metal if applied in any other way. Automatic arc welding is ideally suited to many repetitive welding operations involved in turning out the tremendous quantity of each component part. Rear axle housings are made from rolled plate formed into a tube, the seam being welded by use of atomic H arc welding process. The welded joint obtained in this way is so strong and ductile that it successfully withstands the piercing and repeated heating, expanding, swaging and forging operations that are necessary to achieve the final shape. Drive shafts, radius rods and torque tubes are made using the automatic arc welding equipment, with lightly coated electrodes. Large dies used in pressing out fenders are usually made with a body of a good grade of cast steel, while the cutting edges, forming edges or other portions subject to extreme pressures are built up of the desired quality of tool steel, using the atomic-H arc welding process.

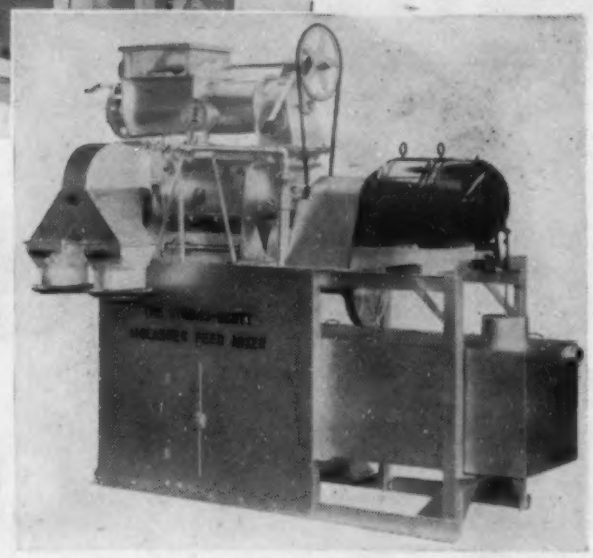
Whitey Sez:

"The difference between bundling in Olde New England and that practiced in the MAURATH *plant — rests in the fact that we keep our product down to five pound uniform packages."*



MAURATH, INC. BUILDER OF BETTER WELDING ELECTRODES IN ALL ANALYSES

C L E V E L A N D

Former construction. Cast mechanism parts and wood base.

Cost $712.00

Present construction. Welded steel parts practically 100%.

Cost $640.00

Courtesy Strong-Scott Mfg. Co., Minneapolis, Minn.

SAVED $72.00 by changeover to WELDED STEEL

● Redesign of this molasses feed mixer for welded steel construction resulted in a stronger, lighter and better looking product with cost savings of $72.00. Also service economy is improved because the base is permanently rigid, avoiding troubles formerly had due to misalignment. These mixers are welded with Lincoln *"Shield-Arc"* Welders and "Fleetweld" Electrodes.

You too can lower costs and improve your products with WELDED construction. For valuable guidance, consult the nearest Lincoln office or mail the coupon.

Studies of the Spot Welding of Low-carbon and Stainless Steels. W. F. HESS & R. L. RINGER, JR. (Rensselaer Polytech. Inst.) *Welding J., N. Y.,* Vol. 17, Oct. 1938, Suppl. pp. 39-48. Original research with a survey introduction of the lack of specific, quantitative information in the literature on spot welding. To remedy the latter defect, the authors map out the logic of a research program in which new facts are to be obtained under standard conditions to permit correlation of later research and data of other researchers. The problem was to determine the currents required to give best welds under varying conditions of pressure, time and electrode size. The methods selected for evaluation of welds were the shear test or tension on a lap weld, and microscopic examination. The latter gave information of highest value, since welds on either side of optimum current, pressure and time could be easily recognized. Methods of measuring current and calculating contact resistances are discussed, together with data presented in numerous curves for stainless steels. The results of microscopic examination of welds in stainless steels and mild steel are discussed from the many actual micros illustrated, and are correlated with the results of physical tests. Of the 9 conclusions reached, the following are the most important: (1) Maximum strength always occurs for maximum current that can be used without expulsion of metal during welding; (2) expulsion of metal during welding should be avoided to prevent cavitation, indentation and loss of strength; (3) 40-70% penetration of sheet thickness by fused metal is associated with the best physical properties; (4) microexamination of welds made in 2, 6 and 10 cycles indicates welds in stainless steels may be carried to 10 cycles without appreciable carbide precipitation and (5) microexamination of weld cross-sections can select varying qualities of spot welds. WB (6a)

The Metallurgy of Welding. H. HARRIS. *Quarterly Trans. Inst. Welding, London,* Vol. 1, Oct. 1938, pp. 235-240. Original research data presented for cooling rate and welding tests, mostly on 5% Cr, 0.50% Mo steel. Theisinger's research on hardenability relations in welding is reviewed, with additional substantiating data collected by the author. The transformation rate of the 5% Cr, 0.5% Mo steel at various temperatures is considered in relation to the Bain S-curve. Delayed cracking and high hardenability are related to the long period of austenite stability at the lower temperatures from 875° C. to 1250° C. Data on the hardness obtained for equal cooling rates, and for varied cooling rates from 1000° C. and 1200° C. quench, are given and show that, even if cooled as low as 50° C. per hr., full hardness is retained when cooled from 1200° C. WB (6a)

Weldability of Nickel-alloy Steels Aids Fabrication. J. W. SANDS (Internatl. Nickel Co.) *Welding Engr.,* Vol. 23, Nov. 1938, pp. 27-28. Practical. Advocates selection of a steel with less than 0.20% C in which the strength has been increased by alloying. Alloy steels containing Ni may show 50% or more increase in yield point. Coated electrodes are to be preferred and frequently unalloyed electrodes may be used in the welding of Ni and other alloy steels, since the deposit will be improved by absorption and diffusion of the alloy from the plate, or base metal. A steel with 0.25% C, 2.25% Ni and 0.65% Mn has been used successfully for fabrication of a pressure tank, welded construction, to be operated at a temperature of —75° F. Clad metals often require special welding procedures. CEJ (6a)

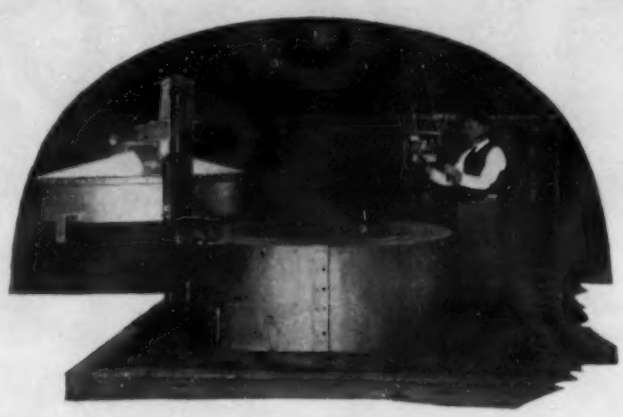
Modern Rail Welding (Neuzeitliche Schienenschweissung) H. FRANKENBUSCH. *Tech. Blätter,* Sept. 18, 1938, pp. 547-550. Discussion of the present status of modern rail welding, referring particularly to the dynamic properties of rail joints. The autogeneously welded rail joint has an essentially higher fatigue limit than the bolted fish plate joint. Joints welded with rods newly developed by I. G. Farben possess fatigue limit twice that of the bolted fish plate joint. The welded joint maintains the same fatigue properties as the rail in service. The results of metallographic investigations of such joints are given. Joining of different rail profiles, welding of crane rails, rail crossings, etc., are also discussed. GN (6a)

Welding Molybdenum Steels, A Review of the Literature to July 1, 1937. W. SPRARAGEN & G. E. CLAUSSEN. *Welding J., N. Y.,* Vol. 17, Nov. 1938, Suppl. pp. 12-21. Another excellent digest by these 2 authors, this time covering the welding of the Mo steels. Seventeen tables present compositions and physical and mechanical properties as gathered from various sources. The Mo steels contain up to 1% Mo, the Mo being particularly effective in raising the strength of low C steel at elevated temperature. In welding, Mo has little effect on hardness. Preheating and stress-relieving of some of the C and alloy-Mo steels is desirable. 47 references. CEJ (6a)

Repair Welding on Molds for the Cast Iron Pipe Industry. *Ind. & Welding,* Vol. 2, Nov. 1938, pp. 58-63. Descriptive. The life of the molds used in the de Lavaud centrifugal pipe casting process has been increased by welding. Many molds of this type are being reclaimed by welding with heavy-coated electrodes. Preheating to 400° F. and continuous welding are of advantage because of the air-hardening characteristics of the steel of which the molds are composed. CEJ (6a)

for better welds *and faster welding*

● Jobs like the reinforcing of bridge members, as pictured above, are done in record time with Page Hi-Tensile "F". The welds are strong and ductile. They resist the effects of heavy vibration.



● Page Hi-Tensile "F" is an all-purpose electrode with a reputation for reducing fabrication costs. It is perfectly suited to construction, maintenance, production work. It saves a lot of time on high-speed, single-pass welding and on jobs in Cor-ten, Cro-man-sil, H-T-50 and other new alloy steels.

Without Scale or Decarburization

Above is shown one unit of the original installation of circular pits we installed in a prominent steel plant—back in 1929—for annealing alloy rod without scale or decarburization.

The original furnaces are still operating daily after practically 10 years' service.

Recently we had the pleasure of installing another similar furnace in this same plant for this same process—another "Repeat Order."

Other interesting installations we have made in prominent steel plants include controlled atmosphere furnaces for bright annealing strip, wire, tubing, sheet and other products, furnaces for billet heating, annealing and normalizing bars and rod and for other products and processes.

We build gas fired, oil fired and electric furnaces—for any product, process or production. Permit us to submit proposals on your furnace requirements.

6b. Non-Ferrous

Welding Thin Aluminum Sheet. E. NERRMANN. *Light Metals*, Vol. 1, Nov. 1938, pp. 348-350. Descriptive. A new method for the resistance welding of thin Al sheet is described, in which the heat is applied by a pair of portable and suitably mounted C electrodes. The sheet to be welded is flanged up with a C electrode at either side. As soon as the metal at the flange begins to run, the electrodes are drawn along the seam as rapidly as the metal melts. Ordinary speeds of welding vary from 500 to 600 mm./min. The only apparatus required is flux, the 2 C electrodes mounted at a small angle to each other in a suitable holder, and a transformer capable of delivering heavy amperages at small voltages. The capacity required varies from 200 to 3,500 watts and the customary voltage varies from 3 to 9. Photomicrographs are shown indicating the excellent bonding obtained with this type of weld. Tests have shown the welds to possess satisfactory physical properties and corrosion resistance. AUS (6b)

The Effect of Current, Pressure and Time on the Shear Strength and Structure of Spot Welds in the Aluminum Alloys. G. O. HOGLUND &. G. S. BERNARD, JR. (Aluminum Co. of America) *Welding J., N. Y.*, Vol. 17, Nov. 1938, Suppl. pp. 45-54. The spot-welding characteristics of the Al alloys are quite different from those of many other materials. For the production of strong welds, careful choice of welding current is important; too low a current is the most frequent cause of weld failure in spot-welded Al construction. The production of strong welds with good appearance requires frequent dressing of the welding tips, and settings that produce more than 30 welds without "pickup" on the welding tips should be suspected of producing weak welds. Time of current dwell and electrode pressure must also be adjusted and controlled. CEJ (6b)

Welding, Brazing and Soldering of Light Metals (Schweiss- und Lötverfahren für Leichtmetalle) KARL HEINEMANN. *Tech. Blätter*, Sept. 25, 1938, pp. 568-570. Review. Considers the present status in this field in Germany, and discusses in detail procedures applied in these processes, including autogeneous welding, fluxes, suitable welding rods, electric resistance welding, C arc, metal arc and Arcatom welding, brazing, soldering and subsequent treatment of welds. GN (6b)

Riveting Methods and Rivet Equipment Used in the German Light Metal Aeroplane Construction. WILHELM PLEINES. *J. Roy. Aeronaut. Soc.*, Vol. 42, Sept. 1938, pp. 761-793. Discussion pp. 793-815. Exhaustive authoritative review. Covers: (1) Fundamental Notions on Riveting in Light Metal Aeroplane Construction. (2) Modern Methods of Riveting in Germany's Light Metal Aircraft Construction: (a) reasons accounting for the difference between riveting methods in aircraft construction and those of general engineering, (b) the different shapes of riveted joints in light metal aeroplane construction and their working methods. (3) Modern Riveting and Drilling Tools. (4) Machine Riveting. Among the 46 illustrations, diagrams show the effect of aging temperature on the changes of shearing stress of duralumin during 120 hrs., and also the age-hardening of 3 Al alloys mainly used for riveting purposes. A recently developed alloy analyzes: 2.08% Cu, 2.1% Mg, 0.8% Si, 0.55% Mn, 0.75% Fe, remainder Al. Contrary to American practice, a German material has been developed which is, in a freshly quenched condition, softer than duralumin, does not age at room temperature during the first 12-24 hrs. after quenching, and the ultimate shear stress of which is not reduced by more than 10% when aging is finished. For a 4-engined Junkers Ju 38, about 1 million rivets are required. Hollow rivets are not used in Germany because they are not as strong as solid ones. Where the hollow rivets require the strength of solid duralumin rivets, they are made of a Ni alloy. This material is corrosion-resisting and is Cd-coated to avoid galvanic attack at contact with Al alloys. Hollow rivets are unsuited to the transmission of high stresses. The problem of riveting structural parts accessible from one side only has not yet been completely solved. The latest development is the Heinkel explosive riveting method (Heinkel *Sprengnietverfahren)*. This rivet has a bore at the free-shaft end and is filled with a firmly pressed-in organic explosive that is non-corrosive in burnt or unburnt condition and that is protected by a coat of varnish. After ignition at 125° C. by an electrically heated tool having a Ag or Al head (not Cu), the free rivet shaft end swells to a barrel shape. The new riveting method is applicable to any material of more than 15% ultimate elongation. Rivet diameter: 2.6-6.0 mm. The execution of this novel type of riveting is described in full detail. A widely used alloy range contains 3.7-4.7% Cu, 0.4-1.0% Mg, 0.1-0.7% Si, 0.3-0.7% Mn, < 0.5% Fe + Ti, < 0.1% Zn and balance Al. EF (6b)

An Investigation of Arc and Gas Welded Joints in Aluminum and Aluminum Alloys. R. K. WELLS & A. G. BISSELL (U. S. Navy Dept.) *Welding J., N. Y.*, Vol. 17, Nov. 1938, Suppl. pp. 55-63. Original research. More than 60 specimens were welded, both with gas and the arc, and the materials under test were carefully analyzed and the test results recorded. Some difficulty was experienced in getting uniformly satisfactory results using the oxyacetylene process, but with oxyhydrogen, very consistent results were obtained. While joints of equal strength were produced in the vertical and flat positions by either gas process, satisfactory vertical welds were not obtained in this investigation using the arc. Al and its commercially available alloys are weldable, but care must be used in the application of welding and in the selection of the welding process. Welding of the complex, high-strength wrought alloys in the heavy sections tested did not produce joints as relatively satisfactory as obtained with the moderate-strength binary alloy, such as 3S. In all the alloys tested, arc welding gave better results than gas welding. CEJ (6b)

Copper Welding—A Résumé. W. C. SWIFT. *Ind. & Welding*, Vol. 2, Oct. 1938, pp. 49-52; Nov. 1938, pp. 50-52. Welding difficulties are encountered due to the high heat conductivity and to the presence of oxides in the Cu. The use of deoxidized Cu eliminates one of these troubles, while the use of a filler rod alloyed with some metal to reduce the temperature of fusion is helpful. A great deal of Cu is gas-welded with Si-bronze filler rods (96% Cu, 3% Si, and 1% Mn, Sn, Zn, or Fe). In Europe, large use is made of Cu filler rods alloyed with Ag, but these rods are quite expensive and the welds are no better than those made in America with deoxidized rods. The use of a long C arc with a 95% of parent metal strength and sufficient ductility to be folded P-bronze D high-P filler rod gives high speed welds with 90%- on themselves without cracking. CEJ (6b)

Copper and Copper Alloys. W. C. SWIFT (Compressed Ind. Gases, Inc.) *Welding Engr.*, Vol. 23, Dec. 1938, pp. 30-33. Practical. Suggests use of terms "bronze-welding" to describe any open "V" type joint, and "brazing" any joint where the base metals are closely fitted and the brazing metal is flowed between the proximate surfaces. The problem of supplying sufficient heat limits efficient gas welding to the smaller and medium size pieces of sheet and plate. Recommends the use of a long C arc, ¾-1¼ in., with high voltage and straight polarity. Best results are obtained with the use of a phosphor bronze D rod, with high Sn and P. CEJ (6b)

7·FINISHING

Pickling, Cleaning, Sandblasting and Polishing. Electroplating, Metallizing, Galvanizing and Tinning. Coloring, 'Oxidizing' and Non-Metallic Finishing.

H. S. RAWDON, SECTION EDITOR

Galvanizing Practice and Galvanized Steel. E. J. GROOM. *Metallurgist (Suppl. Engineer),* Oct. 1938, pp. 162-164. Review. Most notable recent improvements have been in the organization and plant handling rather than in the metallurgy of galvanizing. Zinc-ammonium chloride is replacing ammonium chloride as a flux, but its superiority is not yet fully established. Convection-heating of the bath is believed to eliminate local overheating and therefore to diminish attack of the steel pot by the molten Zn and contamination of the bath with Fe. Pre-heating of the work not only increases pot life but reduces the thickness of the brittle Fe-Zn alloy layer. Of the common addition agents to Zn baths, small amounts of Sn or Sb—added to enhance spangle formation—are not detrimental to corrosion resistance or mechanical properties; Al—added to reduce viscosity and thereby increase pliability—may embrittle the coating if too much is present. Methods for improving corrosion resistance include treatment with S vapor, phosphates, Hg salts, oils or resins, chromates or molybdates. The last-named results in iridescent or dark brown films and may, like coppering, be a useful source of "eye-appeal." Little work has been done on types of finishing or priming coats most suitable for painting weathered or chemically roughened surfaces. In hot-dip galvanizing, heavy coatings offer maximum corrosion resistance. Electro-galvanizing offers certain advantages over hot-dip, but some of these—*e.g.* the feasibility of electrogalvanizing to any desired thickness—have not been widely applied. Electrogalvanizing does not always give a uniform structure. Although there is still some question as to the effect of the purity of the deposited metal on its corrosion resistance, some authors have published results indicating that purity and durability are insignificantly related, but that durability bears a straight-line relationship to thickness. 15 references. 7a. Electrolytic Methods

Some Recent Methods for the Determination of Pores in Zinc Coatings on Iron (Ueber einige neue Verfahren zum Nachweis von Undichtigkeiten in Zinküberzügen auf Eisen) GEORG GARRE. *Chem. Z.,* Vol. 62, Oct. 19, 1938, pp. 759-761. Review. For Fe coated with a nobler metal, such as Ni, Cr, Cu, etc., the ferroxyl indicator is mainly used or filter paper, soaked with potassium ferricyanide solution is applied. For the less noble Zn coatings, however, a new agent—potassium ferricyanide with additions of oxalic acid and H_2O_2—is recommended. Faulty spots in the coat (and also free Fe particles) cause a blue precipitation in the solution. Dilute potassium permanganate gives black discoloration. Increase in sensitivity and saving in time is obtained by using an electrolytic method. Potassium ferrocyanide is used in this case, and a strong electrolyte is added; the specimen is made the anode at 4v. Gas develops at faulty spots, which are later recognized by a blue deposit. Traces of Fe on the Zn surface do not react and cannot, therefore, be confused with pores. The method can be applied not only to Zn but to all coatings on Fe. RPS (7a)

Studies of Some Physico-chemical Factors in the Electrodeposition of Silver. SHRID HAR SARVOTTAM JOSHI & S. PADMANABHAN. *J. Ind. Chem. Soc.,* Vol. 15, Apr. 1938, pp. 176-190. Original research. Results are given for the best conditions for the production of smooth and adherent deposits of Ag. Data are given on the duration of electrolysis, interelectrode distance, concentration of electrolyte, temperature, current and the effect of addition agents, such as gelatine, turpentine and carbon disulphide. Measurements are made of the cathode efficiency of Ag in the presence of methyl alcohol, ethyl alcohol and acetone, the proportions of which were varied over a wide range. Curves correlating the above 2 quantities show marked discontinuities, which indicate a complex formation in the conducting medium. Data are also given for the conductivity, refractive index, density, transport number and viscosity. EF (7a)

Adherence of Electrodeposited Zinc to Aluminum Cathodes. H. R. HANLEY & C. Y. CLAYTON (Mo. School of Mines) *Metals* Tech., Vol. 5, Oct. 1938, T.P. No. 983, 8 pp. Original research. The adherence of Zn coatings deposited from different electrolytes on Al sheet whose surface was varied was studied by measuring the pull required to strip the deposit. Although some impurities in the solution, which are plated with the Zn, may increase the load force required for the stripping of deposits, this feature is not regarded as pertinent to the subject of adherence because the purification system can prevent the presence of these objectionable substances. Impurities in solution that promote the dissolving of the deposited Zn in the acid electrolyte, as well as abnormal etching of the Al cathode, may be the starting point of adverse roughening of the Al plate. This roughened surface becomes more deeply etched and hastens the time when the Zn deposit tends to adhere more tightly. The partial cathodic Zn protection of the Al plate is not sufficient to prevent the development of the adverse surface. The Al plate that is the hardest develops adverse surfaces at the slowest rate. JLG (7a)

Modern Electrogalvanizing Processes (Neuzeitliche Verfahren der Elektroverzinkung) H. FISCHER & H. BAERMANN. *Korrosion u. Metallschutz,* Vol. 14, Oct./Nov. 1938, pp. 356-364. Review. Properties, advantages and disadvantages, especially in comparison with Cd coatings, of the currently-used Zn-plating methods are discussed exhaustively on the basis of literature and experiments. Bright-Zn plating methods are more economical (from the German point of view) than bright Ni and Cd plating processes, and fully equivalent in serviceability. Hard Zn deposits can be obtained with a Cu-containing alkaline Zn bath; such deposits lose their reflectivity by tarnishing much less than do brass, Ni or ordinary Zn coatings. High current densities, up to 5 amp./dm.^{2}, give Zn deposits equivalent to Cd in corrosion protection. Protection can be increased by subsequent treatment in a chromate bath. Hard-Zn depositing methods give less corrosion protection than the other Zn plating methods but these films can be used as a basis for Cr plating. 28 references. Ha (7a)

Activated Carbon in Electroplating Solutions. W. A. HELBIG. *Metal Ind., N. Y.,* Vol. 36, Dec. 1938, pp. 553-555. Excessive suspended matter, traces of lubricating oil, traces of organic matter from rubber tank linings, decomposition products from brightening and anti-pitting agents, etc., may cause trouble at the plating surface. These troublesome impurities can be removed by a combination of activated C treatment and filtration. The technique of precoating the filter medium with activated C is discussed. Activated C for use in electroplating solutions should be acid-washed, ground so that not over 60% will pass a 300 mesh sieve, and should have a high bulk density (apparent density of 0.40-0.45, equivalent to 25-28 lbs/ft.^{3}) CBJ (7a)

Effects of Sodium Cyanide, Sodium Carbonate and Rochelle Salt on the Cathode Efficiency of a Copper Electroplating Solution. ALBERT HIRSCH (Snyder Inc.) *Monthly Rev. Am. Electroplaters' Soc.,* Vol. 25, Nov. 1938, pp. 823-830. Original research. The addition of Na_2CO_3 or Rochelle salt to a copper cyanide bath increased the cathode current efficiency. As a result of the investigation, the following bath is suggested: NaCN, 50 g./l.; free NaCN, 15 g./l.; CuCN, 45 g./l.; Rochelle salt, 45 g./l.; Na_2CO_3, 45 g./1. At 55° C. and a current density of 0.4 amp./dm.^{2}, a good deposit is obtained with a cathode current efficiency of 95%. AB (7a)

Alkali Cleaners and Acids on Lead. GEORGE B. HOGABOOM. *Metal Cleaning Finishing,* Vol. 10, Nov. 1938, p. 740. Practical. Pb is attacked by alkali cleaners with the formation of a film upon which plated coatings do not adhere well. The following cleaning procedure is recommended: Clean the Pb in alkali without the use of current; scratch brush with a wire brush rotating below 850 r.p.m.; dip in clean alkali for a few seconds, then in 10% H_2SO_4; follow by a cyanide dip and plate in the cyanide Cu or brass bath. The current used should be 10-15 amp./ft.^{2} The gassing at higher current densities causes attack of the Pb. AB (7a)

7b. Non-Electrolytic Methods

Submerged Heat. *Steel*, Vol. 103, Oct. 10, 1938, pp. 84, 86, 103. Industrial note describing automatic, submerged combustion system, (Submerged Combustion Co. of America, Hammond, Ind.), for heating and agitating pickling baths.When starting button is pressed a gas- and air-compressor is started which purges burner manifold and combustion chamber of solution that fills them. Simultaneously a hot-wire igniter is heated to incandescence and ignites pilot gas jet that is admitted into burner after a predetermined time. Main gas flow first is permitted to pass through system and then becomes ignited from pilot. Burner plate, located about 4 or 5 in. beneath solution level for cooling, directs flame through a tubular combustion chamber that conducts combustion products down to and across tank bottom where they may be vented and distributed to give rate of agitation desired. Thermostats actuate burner control mechanism and permit constant flow of air through solution, gas flow being turned on or off as heat requirements demand. This maintains a constant rate of agitation regardless of solution temperature or rate of heat input. Solution temperature can be controlled as close as ½° F. when necessary. The burner can be set to give any flue-gas analysis desired. The main advantage of the system is extreme agitation produced, which increases production rate. Average pickling time on various grades of steel will be 30-60% of former practice if operating temperature of bath with submerged combustion is the same as it was with steam. About 25-50% of acid added during life of solution can be saved. Total saving amounts to about 50% of present pickling costs. The system is flexible, and produces fewer rejects and a more uniform, higher quality product. MS (7b)

Piston Rings. *Steel*, Vol. 103, Nov. 28, 1938, pp. 50-51. Industrial note. New "Ferrox" process, developed by the Perfect Circle Co., Hagerstown, Ind., produces a black magnetic oxide surface on piston-rings for a depth of about 0.0005 in. [Involves heating at 1250° F. in an oxidizing atmosphere.] This surface serves to polish the cylinder wall and eliminate scuffing and scoring. Tests have shown that "Ferroxed" surfaces wear 40-90% slower, even when 50% greater pressures are applied against them. Treatment seems to be applicable to any Fe-bearing surface. MS (7b)

The Temperature Coefficient of the Acid Corrosion of Iron in the Presence of Organic Substances (Ueber den Temperaturkoeffizienten der Säuerekorrosion des Eisens bei Gegenwart organischer Stoffe) W. MACHU. *Korrosion u. Metallschutz*, Vol. 14, Oct./Nov. 1938, pp. 324-340. Review plus research, on the velocity of the chemical reaction in the dissolution of a heterogeneous system, *e.g.* corrosion of Fe in acids. The exhaustive tests show that the extremely high temperature coefficient of the corrosion of Fe in 20% H_2SO_4 is due exclusively to the convection effect of the liquid layer touching the metal. The temperature coefficient can be reduced considerably by suppressing the strong H evolution with an addition of organic inhibitors. The low temperature coefficient in the presence of organic substances results from the formation of a protective adsorbed layer of the inhibitor on the metal surface which makes the diffusion of acid to metal very difficult. The temperature coefficient of the corrosion of Fe *oxide*, however, is *not* affected by the presence of organic inhibitors, even at high concentration, since a protective layer can not be formed on the Fe oxide. The action of an inhibitor can be fully explained by this theory of diffusion velocity. 12 references. Ha (7b)

Attacking Trade Waste Problems. G. M. DARBY & C. L. KNOWLES (Dorr Co.) *Chem. & Met. Eng.*, Vol. 45, Oct. 1938, pp. 528-532. General survey, including discussion of waste from steel pickling operations. It is probably most economical merely to dump spent pickling liquor into streams, but inasmuch as this practice is widely forbidden for sanitation reasons, the problem becomes one of salvaging in order to defray as much as possible of the expense incurred in keeping the liquors from the streams. Crystallization of the ferrous sulphate for sale or conversion to a salable product is being studied. Liming, followed by flocculation, clarification and dewatering of the thickener underflow is also a possible answer. The Ferron process of treating pickling liquor with lime under controlled pH and temperature conditions to give a thick slurry, which is filter pressed, disintegrated and dried, provides a product claimed to be marketable as an insulation and building material. The recovery of iron oxide and sulphur or sulphuric acid is a logical technical answer. Steel plants requiring an immediate solution to the problem will probably find that neutralization and filtering requires the least expensive layout. PRK + FPP (7b)

Surface Protection of Zinc and Zinc Alloys by Chromate Coatings (Oberflächenschutz von Zink und Zinklegierungen durch Chromatüberzüge) H. FISCHER & N. BUDILOFF. *Korrosion u. Metallschutz*, Vol. 14, Oct./Nov. 1938, pp. 353-356. Practical. The properties of a chromate film produced on a Zn alloy by immersion in a suitable solution (MBV process) are discussed. The immersion period should be less than 60 secs., otherwise the coatings are loosened too much. Appearance and adherence do not change with increased bath temperature up to 45° C. A chromate film protects Zn and Zn alloys against corrosion in NaCl and H_2O_2 solutions, but in a continually renewed corrosive agent, *e.g.* salt-water spray, the protective action diminishes gradually as the film is destroyed. 6 references. Ha (7b)

Behavior of Different Kinds of Sulphuric Acid in Pickling Strip Steel (Das Verhalten verschiedener Schwefelsäuren in der Bandstahlbeizerei) W. UFER & A. DÖRING. *Stahl u. Eisen*, Vol. 58, Oct. 13, 1938, pp. 1107-1111. Practical. Laboratory and plant tests were made of chamber and contact process H_2SO_4 manufactured from different raw materials in determining the pickling activity of the different acids. With pure dilute acids without any additions, appreciable differences in the rate of attack and in acid consumption per ton of strip steel pickled were observed. Certain additions, such as NaCl, $NaNO_3$ and nitrosyl-sulphuric acid increased the differences between acids, but with a good grade of acid property diluted, these additions were not detrimental. Dilution to about 15% H_2SO_4 gave the best pickling results, the consumption being about 10-10.6 kg. of 96% H_2SO_4 per ton of strip steel. SE (7b)

Modern Pickling Practice. WALLACE G. IMHOFF (Wallace G. Imhoff Co.) *Metal Cleaning Finishing*, Vol. 10, Oct. 1938, pp. 668-672. Review. Pickle liquors become slow in action when they contain about 12-25% of $FeSO_4$. The disposal of spent liquors by running them into streams and rivers has created a serious pollution problem. The author reviews some of the proposed methods of disposing of spent liquors. These include treatment with lime, recovery of $FeSO_4$ by evaporation and spraying the solution into a furnace and condensing acid vapors. AB (7b)

Refinement of Ground Surfaces. H. S. INDGE (Norton Co.) *Mech. Eng.*, Vol. 60, Nov. 1938, pp. 807-812. Descriptive. Methods, processes and equipment to produce superfine finishes in the finishing of metal parts are described. The necessity of such refinement is warranted by the accuracy of dimensions required nowadays. Surface finishes are built up, a finer abrasive being used for each subsequent operation. Lapping and honing operations permit production of superfine surfaces at high speed and low cost. Ha (7b)

High Speed Galvanizing. *Steel,* Vol. 103, Dec. 19, 1938, pp. 62-63. Descriptive. Modern equipment for continuous galvanizing of steel sheets operates at 25-100 ft./min. Furnace design is an important factor in successful practice at these speeds. A set-up widely used on such installations utilizes the "impact" method of firing. Homogeneous air-gas mixture is directed at an angle into the interstices of a bed formed of refractory lumps piled loosely in combustion chamber. Very rapid and complete combustion takes place. Hot combustion products then pass over a bridge wall and come in contact first with upper portion of kettle. Then, by descending through passage between bridge wall and side of kettle, give up heat to kettle side walls until they pass to flue along bottom of setting. Heat transfer is by radiation, conduction and convection. Most of the heat is applied at top, with burners relatively high up on sides of setting. Kettle bottom is shielded from hot gases to provide a place where dross may settle and be undisturbed. Burners are distributed around 3 sides of the kettle at close intervals. Maximum fuel input is applied to end of kettle where sheets enter. No burners are used on exit end. Fuel control is automatic. Size of kettle is proportioned to permit maximum production rate desired with a conservative heat transfer rate through kettle walls. Where batteries of sheet galvanizing furnaces are used, it has been found useful to install a hot metal holding furnace and a Pb pot for preheating rolls for galvanizing machine. MS (7b)

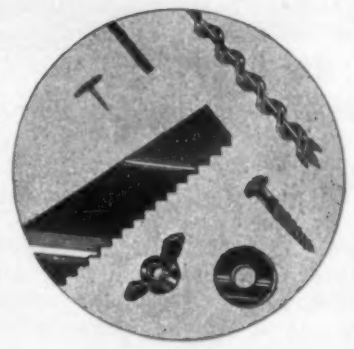
Effect of Corrosion on the Durability of Paint Films. V. M. DARSEY (Parker Rust-Proof Co.) *Ind. Eng. Chem.,* Vol. 30, Oct. 1938, pp. 1147-1152. Practical. The durability of paint coatings applied to different metals depends, to a great extent, on the corrodibility of the base metal in the environment to which it is exposed. Chemical treatment of easily corrodible metals, to convert their surfaces to a more stable and less reactive phosphate coating, materially increases the durability of paint coatings. This treatment provides increased adhesion of paint film to metal and retards peeling or chipping away from abraded areas. Paint coatings containing a corrosion-inhibiting substance possess greater durability than similar paint coatings without an inhibitor. Most paint troubles have their beginning at the point of contact between paint and metal surface, and if a painting schedule is recommended, it is important that the treatment of the surface prior to painting be specified. 10 references. MEH (7b)

Looking Over the Porcelain Enameler's Shoulder. JOSEPH D. WALKER. *Metal Cleaning Finishing,* Vol. 10, Nov. 1938, pp. 750-758. Review. A clean metal surface is required for enameling. Castings are first sand blasted, the most efficient conditions being obtained with a ⅜ in. nozzle and 70-80 lb. air pressure. Oil and grease are cleaned from sheet metal by burning off in an annealing process, or by a hot alkaline bath. As a cleaner for surfaces that are to be enameled, the organic solvents are said to have some disadvantages compared with alkaline cleaners. The pieces are pickled 10-20 min. Absorption of H in the process sometimes causes blistering when the ware is enameled. After pickling, the ware is rinsed, dipped into a weak alkaline solution to neutralize traces of acid, and rapidly dried in a hot dryer. AB (7b)

Selection of Compounds for Automatic Buffing. WALTER R. MEYER. *Metal Ind., N. Y.,* Vol. 36, Dec. 1938, pp. 567-569. Practical. Functions of buffing compounds are: (1) To serve as a medium to transmit the pressure of the work against the wheel, or vice versa, for accomplishing cold-working and flow, and (2) to lubricate the wheel-metal interface by retarding oxidation of the metal, overheating of the buff and metal by excessive frictional heat, and to act as a medium for the removal of the solid products of buffing. Cost factors to be considered in testing buffing compounds include: (1) Cost of the compound per unit of buffed work, (2) cost of buffing wheel per unit of work, (3) labor and overhead per unit of work and (4) added or lowered cleaning costs. CBJ (7b)

Grinding and Polishing Fabricated Stainless Steel. C. A. CARLSON (Norton Co.) *Ind. & Welding,* Vol. 11, Oct. 1938, pp. 44-48. Practical. Stainless steels are finished by grinding and polishing to improve the resistance to tarnish and corrosion. As heat tinting takes place at 400° F., care must be taken to use free cutting grinding wheels and a plentiful supply of coolant or lubricant whenever possible. General information for grinding, polishing and buffing is included. The freedom of the finished surface from minute foreign particles and the complete removal of all spots, scratches, pit holes or even tiny imperfections decidedly influence the retention of the luster on any finished piece of stainless steel. CEJ (7b)

Modern Pickling Practice. WALLACE G. IMHOFF (Wallace G. Imhoff Co.) *Metal Cleaning Finishing,* Vol. 10, Nov. 1938, pp. 736-738. The author describes the development of acid-resisting materials for pickling tanks and their accessories and for sewers and drains used in the disposal of spent liquor. The principal materials used are alloys such as duriron, phosphor-bronze, and nickel alloys; acid proof brick; and rubber lined steel. AB (7b)



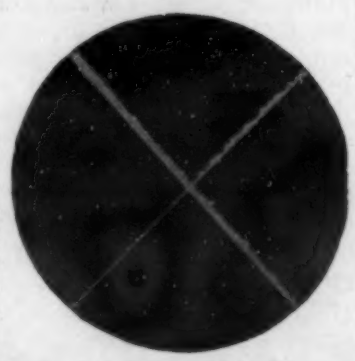
Trade Mark Reg.

the JETAL process

Threefold Superiority

1 A Beautiful Finish

JETAL . . . simple . . . economical . . . enhances the appearance of products of iron or steel. Its lustrous, rich black finish does not alter dimensions or surface textures. JETAL is an oxide of iron and a part of the metal itself.



2 An Excellent Paint Base

JETAL is an excellent base for modern paints, lacquers and enamels. It retards rust formation . . . also allows subsequent coatings to develop their true adherence to the metal. Cut shows impact test made on enamel over JETAL. Note that the enamel film is still firmly adherent to the steel . . . is finally fractured only when the steel itself parts. In such impact tests JETAL and enamel showed 300% more adherence than enamel and steel and no breakdown after 2,000 hours in a humidity cabinet.

3 An Effective Rust-Resistant

JETALized iron and steel, dipped in our Jet-oil, stops corrosion attack for long periods of time—in laboratory tests showed no appreciable attack after 165 hours in salt spray.

The JETAL Process is known throughout the world for its effectiveness and economy. Ask for descriptive folder giving full details of the JETAL bath and its use.

8·TESTING AND CONTROL

Methods and Equipment. Physical and Mechanical Property Testing. X-Ray and Magnetic Inspection. Spectrographic Analysis.

W. A. TUCKER, L. S. REID AND G. R. HARRISON, SECTION EDITORS

Light Metal Tomography. H. W. GREENWOOD. *Light Metals,* Vol. 1, Dec. 1938, pp. 390-393. Review. Tomography is a division of radiography that deals with the photography of a particular plane in an object while leaving out undesired detail in other planes. While this technique was developed for medical radiography, it is recommended for certain purposes in work with metals where it is essential that the location of faults be exactly known. For example, if 2 cavities are present in a casting, one below the other in line with the X-ray target, there is no way of determining, in one picture, which lies above the other. Furthermore, in many instances confusion would exist as to whether or not the pattern on the film were due to one complex cavity or 2 or more cavities whose images were superimposed on the film. The tomograph is an X-ray machine rigged so that the film and X-ray tube are fixed to opposite ends of a beam or bar. This member is pivoted at a point so that the elevation of the pivot corresponds to the elevation of the plane in the object that is to be photographed. The tube and film move back and forth, with the object between, in planes parallel to the plane of the film. In effect, the tube and film holder constitute the ends of an oscillating pendulum. But these ends, as stated above, do not describe arcs, but move linearly. From simple geometrical considerations it is readily apparent that points in the pivotal plane will be projected as points on the film, but points in other planes will be projected as lines; the length of the lines, of course, vary with the distance from the pivotal plane (photographed plane). Hence, points at distances of over about ¼ in. from the desired plane will be considerably blurred, showing up clearly, in contrast, the sharpness of points in the desired (pivotal) plane. AUS (T-8)

Effect of an Elastic Anisotropy on the X-ray Measurement of Stresses (Einfluss einer elastischen Anisotropie auf die röntgenographische Messung von Spannungen) R. GLOCKER. *Z. tech. Physik,* Vol. 19, Oct. 1938, pp. 289-293. Theoretical. The elastic anisotropy of polycrystalline Fe to be expected in the X-ray measurement of strains is calculated on the assumption that the individual crystallites of a metal deform independently of each other. It is found to be much greater and to vary with the angle of incidence of the X-ray beam in quite a different manner than according to the approximate calculation of Möller & Barbers (*Metals and Alloys,* Vol. 7, Mar. 1936, p. MA 138 R/2). Comparison with the X-ray measurements of the above authors and of Möller & Strunk (*Metals and Alloys,* Vol. 9, Sept. 1938, p. MA 566 R/5) shows that the newly calculated values of elastic anisotropy are much too high, proving that the assumption of an independent deformation of the individual crystallites is incorrect. At the present-day accuracy of X-ray measurements of individual stresses at an angle of incidence of 45°, the effect of the elastic anisotropy may be disregarded, so that the technical values of the modulus of elasticity and the Poisson number can be used safely in evaluating the results of X-ray measurements. ORS (T-8)

Influence of the Speed of the Testing Machine on the Observed Mechanical Properties of Certain Austenitic Steels (Influenza della velocita di trazione sulle propieta meccaniche di alcuni acciai austenitici) I. MUSATTI & E. HUGONY. *Met. Ital.,* Vol. 30, Oct. 1938, pp. 545-564. Original research. The effect of varying the speed of the testing machine from 0.5 to 90 mm./min. on the observed tensile and elongation values of several austenitic and ferritic Cr-Ni steels was investigated. Samples containing 8.50-31.96% Ni; 8.35-26.62% Cr, were compared. Austenitic steels whose compositions were close to the line separating the martensite and ferrite areas of the structural diagram showed a decrease in tensile and elongation as the speed of testing increased, a phenomenon not shown by steels whose composition was well inside the austenitic area. Austenitic steels containing Mn, on the contrary, show increasing tensile and elongation as the speed of the testing machine is increased. Ferritic steels do not appear to be influenced greatly either way. AWC (T-8)

Sound as an Aid to Research (Der Klang als Forschungsmittel) FRITZ FÖRSTER. *Umschau,* Vol. 42, Nov. 6, 1938, pp. 1025-1029. Up-to-date review. The damping of sound in a specimen is strongly influenced by flaws in the material. If an oscillating body has a crack, the adjacent planes in the crack rub against each other, so that the oscillation energy is transformed to friction heat. Different materials have different damping characteristics. There is a simple relationship between the natural frequency and the modulus of elasticity of a material. Both damping and the modulus of elasticity can be determined easily by means of sound. Curves of resonance, *i.e.* amplitude against frequency, are plotted. A wide curve corresponds to strong damping and vice versa. The specimen can be mounted in a furnace or in a cooling tank during the test. Almost all metallographic changes (transformation, change in distribution, recrystallization, grain growth, change in plastic behavior, magnetic changes, etc.) show up in the sound characteristics. Internal stresses are even more evident in the sound properties than are transformations. The beneficial effect of working on sintered alloys, especially the increasing density, can be closely watched by this method. The hardening process can be controlled and intercrystalline corrosion detected. It is emphasized that the specimen is not subject to any stress during testing. With a single exception (ferromagnetic materials), damping is a well defined physical constant. RPS (T-8)

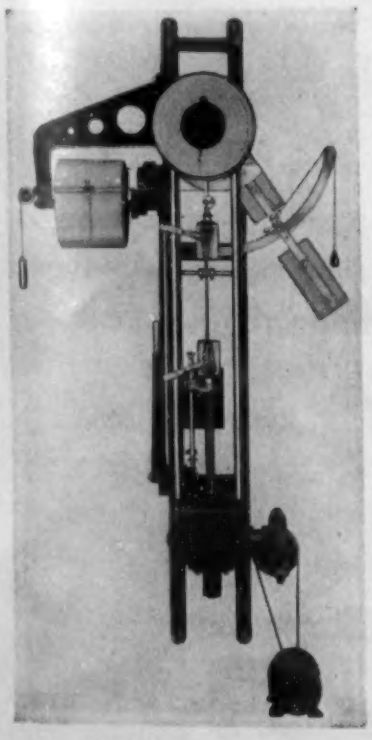
An Investigation of Notch Effect in Static Tests (Die Untersuchung von Kerbwirkungen im statischen Belastungsversuch) W. SPÄTH. *Metallwirtschaft,* Vol. 17, Oct. 28, 1938, pp. 1133-1134. Discussion. Several factors are mentioned that should be considered in evaluating the results obtained from notched tensile specimens. Effects such as (a) stress concentration caused by the notch effect, (b) decrease in the relative elongation of a gage length that is considerably greater than the amount of material deforming, and (c) the influence on the tensile strength of the essentially higher rate of deformation at the notch base should be differentiated. GA (T-8)

8a. Fatigue Testing

H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

X-ray Determination of the Change in Distribution of Internal Stresses During Alternating Bending Tests (Röntgenographische Bestimmungen der zeitlichen Änderung des Eigenspannungszustandes bei Biegewechselbeanspruchung) F. GISEN & R. GLOCKER. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 297-298. Experimental. An X-ray investigation was made of the stresses about a hole bored horizontally through a cylindrical endurance (bending) specimen. The samples had been cold worked parallel to the cross section of the hole. Before testing compression stresses were present in the regions that had been cold worked during preparation of the sample, and both compression and tensile stresses were present in other regions. After testing near the endurance limit, the specimen seemed to be covered with a "skin of compression stresses." GD (8a)



Critical Review of Recent and Important Endurance Tests on Aluminum Forging Alloys (Kritische Zusammenstellung der neuesten und wichtigsten Dauerfestigkeitsuntersuchungen von Aluminium-Knetlegierungen) H. WESTHOFF. *Z. Metallkunde,* Vol. 30, Aug. 1938, pp. 258-265. A careful review of the literature leads to the conclusion that values for endurance strength cannot be evaluated except for a specific number of cycles, and that tests involving a large number of alternations are still incomplete. Bibliography attached. GDC (8a)

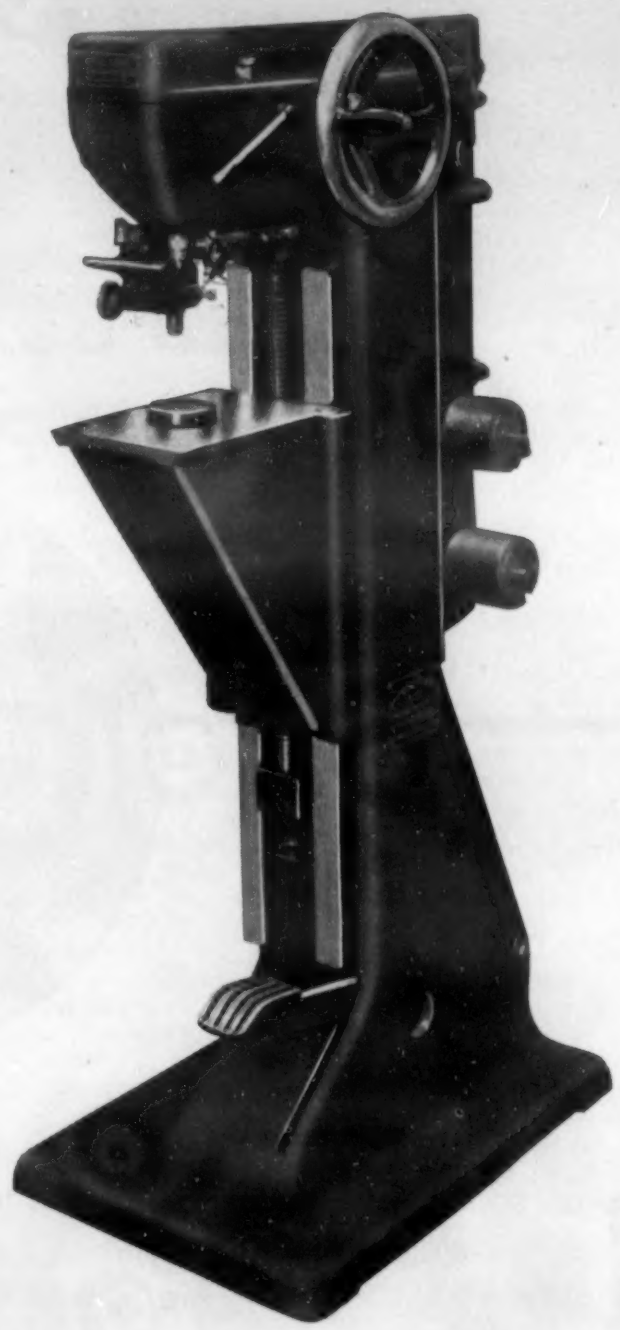
The Fatigue of Metals. YOICHI KIDANI. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Oct. 1938, pp. 1042-1052. In English. Original research. A statistical theory of fatigue is developed. The fatigue of metals with repeated eccentric loading is classified in 2 groups, that occurring in a quasi-elastic region, and that occurring in the plastic region. The properties of internal friction of metals for quasi-elastic and plastic repetition in torsion is mathematically treated. A table presents the values of fatigue limits (torsional stress) for 3 steels, Ni, Cu, bronze, Al and magnalium. Experimental data obtained on cylindrical specimens of 0.6%, 0.3%, 0.1% C steel and Cu tested in the Kuraishi-Kuno repeated torsion machine under severe torsional stresses are in excellent agreement with the author's theoretical formula which, in turn, agree with the Dalby-Stromeyer equation $S = F + C(10^6/N_F)^{1/4}$, where S is a given stress, F is fatigue limit when N_F = infinity, C is a constant (the slope of the line obtained by plotting S for a given specimen against N_F, the number of cycles to failure. EF (8a)

Oscillating Stresses and Crystal State (Wechselbeanspruchung und Kristallzustand) H. MÖLLER & M. HEMPEL. *Mitt. Kaiser-Wilhelm Inst. Eisenforsch., Düsseldorf,* Vol. 20, No. 17, 1938, pp. 229-238. Research. Crystal behavior and the possibility of deformation at fatigue fracture were further investigated and, in general, results of previous investigations were corroborated (see also *Metals and Alloys,* Vol. 9, Aug. 1938, p. MA 498R/8). The strong disturbances of the crystal lattice associated with fatigue fracture were always observed only in the completely fractured specimen and cannot, therefore, be considered as a cause of fracture but must be considered as an accompanying phenomenon. The tests are described in detail, and X-ray pictures show the progress of the structural change after every few hundred-thousand cycles during the fatigue test. Ha (8a)

Distinction between the Crystalline Mechanism of Static and Dynamic Rupture (Distinction entre le Mécanism Cristalline de la Rupture Statique et celui de la Rupture Dynamique) G. A. HOMES & P. DUREZ. *Bull. Classe Sciences Acad. Roy. Belgique,* Vol. 24, Ser. 5 (3), 1938, pp. 159-162. Original research. Whereas the static or instantaneous fracture is characterized by the progressive deformation of all the crystals, the dynamic or fatigue fracture is due to the progressive deformation of only some of the crystals. It is highly possible that a repetition of stresses simply accentuates the initial differences between the strength of the individual crystals. EF (8a)

SCOTT *Improved*
WIRE TESTING MACHINE

Autographic Recorder Magnifies Test Line in Stretch Direction



●

Easy to Operate

Adapted specifically to laboratory investigation and research, this improved Wire Testing Machine permits accurate routine Testing without requiring a skilled operator.

Rigid construction eliminates machine deflection; operates with ¼ H.P. Motor to offer ranges of 0-250 and 0-500 lbs.; or 0-500 and 0-1000 lbs.

How to be SURE of Quality

IN many applications, neither the foundry nor its customers can afford to take chances with quality. A single fault in the internal structure of the metal may render an expensive casting unfit for the particular use for which it was designed.

A dependable and economical method of finding such flaws before they can do any damage is examination by x-ray. And of primary importance is the fact that the finding of a flaw in a large casting is not necessarily a signal for the discard, because the x-ray film that shows the fault is also an accurate guide to repair by welding—a practice followed profitably by many users of industrial x-ray apparatus. Here, then, is a sound reason for employing this modern method of non-destructive testing—by guiding good repair, it can actually save castings, and in some cases save the time and money expended in machining that would ultimately disclose the flaw.

Furthermore, if x-ray examination shows similar faults in the same relative positions in several castings, you have good evidence that an improvement in foundry technique is needed. And many experienced users of x-ray equipment have pointed to the value of x-ray in guiding improvements in foundry methods—improvements that have resulted in as much as doubling the yield from a single melt, and cutting almost to nothing the cost of replacing defective castings produced by techniques not quite up to standard. On pilot castings or on production pieces, x-ray provides information that can be obtained in no other way—information that may enable you to save time and money because it will tell you where and how to achieve better methods.

There you have the story of why many progressive foundries are turning to x-ray for complete examination of certain important castings, and why they are using x-ray routinely in the development of better foundry techniques to assure better quality to their customers.

Why not take advantage now of the services of experienced x-ray engineers to help you apply x-ray profitably in your plant; and you will probably be surprised to find what a modest investment would be required to enable you to enjoy its benefits. Your request for help and information implies no obligation. Just address Dept. I43.

9·METALLOGRAPHY

Structure and Constitution.

J. S. MARSH, SECTION EDITOR

Technique and Possibilities of Microradiography (Technique et Possibilités de la Microradiographie) F. FOURNIER. *Rev. Mét.*, Vol. 35, Aug. 1938, pp. 349-356. Original research. The use of X-rays for examination of the heterogeneity of alloys was impeded by the difficulty of obtaining a film sensitive enough to X-rays and yet so fine grained that it could be examined under the microscope. The Lippmann-Gevaert emulsion is satisfactory and may be examined at 200 X. This method of examination is particularly suited to the light alloys, where there is a considerable difference in atomic number between the constituents. Comparative microradiographs and photomicrographs show the ability of the former to delineate clearly heterogeneities in solid solutions, etc. While the microradiographs are not so valuable for ferrous alloys, they do indicate impurities, cracks, heterogeneities, and micro-inclusions. JZB (9)

The Crystal Structure of Co_2Al_5. A. J. BRADLEY & C. S. CHENG. *Z. Krist.*, Vol. 99, Aug. 1938, pp. 480-487. In English. Original research. The structure of Co_2Al_5 was determined from X-ray powder photographs with the help of the structure factor graphs and figure fields. The unit cell is hexagonal with a = 7.593 A.U. and c = 7.656 A.U. It contains 8 Co atoms and 20 Al atoms. The space group is D^4_{6h}, C 6/mmc. Perpendicular to the hexagonal axis, the atoms are near 4 equidistant planes, each containing 7 atoms. One of the atoms lies on a 3-fold axis, the other 6 grouped around in a symmetrical fashion. EF (9)

Extraction of Oxide Inclusions in High Carbon Iron-Electrolytic Iodine Method. FRANK W. SCOTT (Univ. Minn.) *Metals and Alloys*, Vol. 9, July 1938, pp. 171-174; Aug. 1938, pp. 201-206. Original work on the effect of the presence of metalloids on the recovery of oxides by the electrolytic iodine method. An extensive review of the literature and methods of separating oxide and other non-metallics from steel is given. The experimental work consisted of the extraction of a number of pig irons and specially prepared melts of hypereutectic Fe-C alloys with varying metalloid content. These special melts were made from Armco iron, C, and ferroalloys to yield the composition desired. Previous work has indicated only a slight solution of oxides in this method. The author states that loss of Mn silicate is negligible when the silicate is over 50% SiO_2, though the data from which this conclusion is drawn are not shown clearly. 40 references. WLC (9a)

Investigation of the $\alpha \rightleftarrows \gamma$ Transformation and of the Properties of the α-phase of the Fe-Ni-Si System. O. N. AL'TGAUSEN. *Metallurg*, Vol. 13, Mar. 1938, pp. 3-14. In Russian. Original research. With 0-10% Ni the addition of Si raises the temperature of $\alpha \rightleftarrows \gamma$ changes; with over 10% Ni the addition of Si expands the α plus γ field and lowers the temperature of the beginning and end of $\gamma \rightarrow \alpha$ change. Up to 10% Ni the magnetic saturation increases slightly or remains stationary, but when Ni is increased to above 10% the saturation drops. Presence of Si lowers the saturation value. At a constant Si content, the addition of Ni increases the coercive force in the region where there is a $\alpha \rightleftarrows \gamma$ transformation. Alloys of over 4% Si have a lower coercive value than the others. BZK (9a)

Mechanism of Cementite Dissociation During Graphitization of Pig Iron. E. G. SHUMOVSKII & A. V. ORLOV. *Metallurg*, Vol. 13, Jan. 1938, pp. 25-38. In Russian. Original research. The dynamics of secondary graphitization were observed in a vacuum furnace. Observations lead to the conclusion that transformation mechanism occurs as follows: Under the extended influence of near-eutectoid temperature, the eutectoid cementite tends to assume a globular form which facilitates its solution in the austenite. The small particles of cementite continue to dissolve in the austenite while the larger ones of primary graphite will continue to grow. An attempt is made to support this with the theory of Piwowarsky. The effect of vacuum is to decrease the speed of secondary graphitization. BZK (9a)

The System Iron-Columbium (Das System Eisen-Niob) R. VOGEL & R. ERGANG. *Arch. Eisenhüttenw.*, Vol. 12, Sept. 1938, pp. 155-156. Research. The Fe-Cb diagram was determined thermally and microscopically. The compound Fe_3Cb_2 at 50% Cb, m.p. 1650° C. divides the diagram into 2 eutectic regions, the one at the left occurring at 21% Cb, m.p. 1360° C., and the the one at the right at 73% Cb, m.p. 1515° C. α Fe dissolves about 5% Cb at the 1360° C. eutectic temperature. At 1100° C., the solubility is about 3%, and decreases very little as the temperature goes down. The change in solubility leads to only a small age hardening effect; an increase in hardness after an age-hardening heat treatment from 143 Brinell to 229 Brinell was observed. SE (9a)

Age-toughening of Mild Steel. I. HAGIHARA. *Nippon Kinzoku Gakukai-Si*, Vol. 2, Aug. 1938, pp. 409-413. In Japanese. Original research. Properties of mild steel quenched from above the transformation temperature were varied by aging. The storage (or room-temperature aging) of quenched steel caused a considerable increase in elongation and a reduction in area without an appreciable change in tensile strength. H analysis indicated that the age-toughening phenomenon is due to liberation of H_2, which is absorbed from moist atmosphere during heating in the electric furnace. NS (9a)

The Conversion of Solid Cementite into Iron and Graphite. H. A. SCHWARTZ. *J. Iron Steel Inst.*, Advance Copy No. 14, Oct. 1938, 31 pp. Up-to-date review. The graphitizing action is discussed in light of thermodynamical data and direct experimental evidence. Both the author's own work and other pertinent literature is critically considered in explaining the behavior of Fe during graphitization. 64 references. JLG (9a)

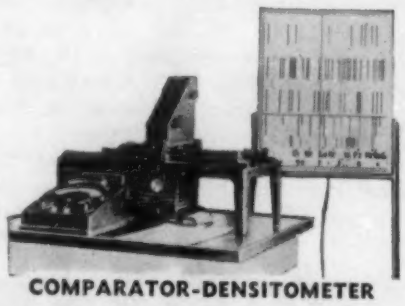
J. S. MARSH, SECTION EDITOR

Kinetics of the Decomposition of Austenite at Constant Temperature. J. B. AUSTIN & R. L. RICKETT (U. S. Steel Corp.) *Metals Tech.*, Vol. 5, Sept. 1938, T.P. No. 964, 20 pp. Mathematical. Measurements of the rate of decomposition of austenite at constant temperature can be made to plot on a straight line if time is plotted on a log. scale and % transformed is plotted on either the "autocatalytic" or the "integrated-probability" scale. The straight-line plot permits easy and rapid interpolation and also permits extrapolation to 1% and 99% transformation. The isothermal rates for a given steel plotted in this manner have the same slope over the temperature range in which austenite transforms to "bainite." Moreover, within this range the time required for completion of a given fraction of the transformation varies inversely with the absolute temperature; that is, $\log t = \frac{a}{T} + b$. For a given steel the constant "a" is independent of the fraction chosen, so that lines representing 1% and 99% are parallel. Below 250° C. the isothermal rate curves show 2 steps instead of one. The rate at which the second reaction goes on is also represented by a straight line on the "log-autocatalytic" or "log-probability" paper. The log of the time required for completion of a given fraction of transformation varies inversely with the absolute temperature, but the lines for different percentage transformations do not have the same slope. There appear to be 2 reactions taking place below 200° C. The first is probably the formation of martensite, but the nature of the second is not known. JLG (9a)

The Constitution of Vanadium Carbide (Étude de la Constitution du Carbure de Vanadium) ANDRÉ MORETTE. *Bull. Soc. Chim.*, Vol. 5, Sect. 5, July 1938, pp. 1063-1069. Original research. Previous literature is summarized, showing that various investigators assume the existence of CV, C_3V_4, CV_5 and CV_2. Mixtures of vanadic anhydride and sugar charcoal were heated in a Moissan arc furnace and alloys containing 7.3-26.6% C by analysis were obtained. In the presence of an excess of C, a compound corresponding to the formula C_3V_4 forms at elevated temperatures. This result has been verified by a metallographic and X-ray analysis. C_3V_4 is face-centered cubic (a = 4.15 A.U.), as is metallic V. EF (9a)

MODERN ANALYSIS

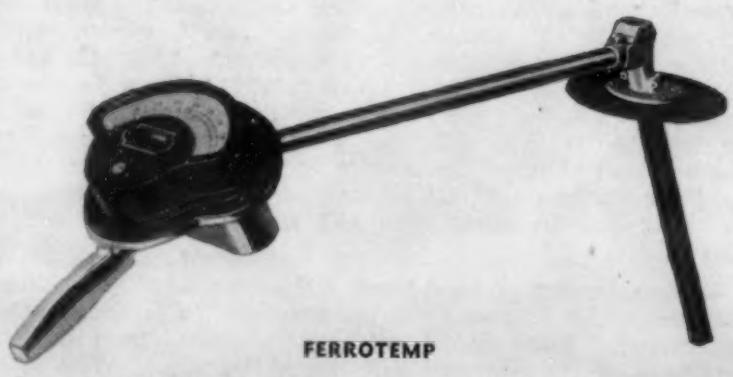


D. C. ARC CABINET

The ARL D. C. arc cabinet gives a controllable pulsating D. C. electrical current for D. C. arc excitation. Equipped with a complete set of electrical indication instruments, switchboard and automatic timer. ARL Cabinets are also available for A. C. arc and high voltage spark excitation.

The ARL Spectrograph has constant dispersion and excellent resolution from 1800 to 10,000 A. U. High photographic speed yielding sharply defined spectrograms. Perfect alignment of all optical units. Film calibration by log sector or dominant constituent lines. Camera holds 100 ft. of film, avoids frequent loading.

ARL SPECTROGRAPH



COMPARATOR-DENSITOMETER

The ARL Comparator projects a master and the unknown spectrogram on the screen for rapid and accurate qualitative analysis.
The ARL Densitometer with motor driven scanning slit, is corrected for scattered light effect and light transmission of plate or film yields unprecedented accuracy and speed.

The Carbon Determinator measures the carbon content of all metals in 2 minutes without sacrifice of accuracy. It is of sturdy construction and remains in calibration.
A Sulphur Determinator is also available which measures the sulphur content of all metals in 5 minutes as accurately as the gravimetric method.

Carbon Determinator

FERROTEMP

Accurate temperature of molten grey iron and white iron with immersion pyrometer. Economical in cost and in use.

An X-ray Study of Dental Amalgams. ALEXANDER R. TROIANO (Harvard Univ.) *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 811, 13 pp. Original research. X-ray diffraction studies were made on amalgams prepared by trituration of Ag_3Sn with Hg, and directly from the elements Ag and Sn with Hg. In general, the equilibrium diagram of Gayler is confirmed, but the theory of setting advanced by her is not consistent with the experimental results. An alternative theory of setting divides the reaction into 2 parts: (1) $Ag_3Sn + Hg \rightarrow \gamma_1 + \delta_2 + Ag_3Sh$ (unattacked), which completes the reaction between solid and liquid and terminates the actual "hardening" reaction. Subsequently, the alloy should tend to approach equilibrium by: (2) $\gamma_1 + \delta_2 + Ag_3Sn$ (unattacked) $\rightarrow \gamma_1 + \gamma_2 \rightarrow \gamma_1 + \gamma_2 + \beta$. After at least 15 days at room temperature, no indication of this latter reaction could be detected. Since the dimensional changes observed immediately after setting are all complete in a few days, the equilibrium reaction can play no part in them. Hence, the explanation by Gayler that contraction may be caused by the formation of β_1 cannot be correct. It is proposed that the expansion be explained by the dendritic growth of the γ_1 phase from the melt, with the subsequent production of voids. Contraction may be explained by the precipitation of δ_2 in the interstices of the dendrites, which would tend to eliminate the voids. Analogy is made to the peritectic reaction. JLG (9b)

Rates of Diffusion of Copper and Zinc in Alpha Brass. ERNEST KIRKENDALL, LARS THOMASSEN & CLAIR UPTHEGROVE (Univ. of Mich.) *Metals Tech.,* Vol. 5, Oct. 1938, T.P. No. 967, 18 pp. Original research. Diffusion was studied by plating Cu on β brass, heating to allow diffusion to take place, and measuring the concentration of Cu by determining the lattice constant of the alloy. Three diffusion coefficients were determined at 3 different temperatures on substantially the same α brass. From the results, it is possible to calculate the probable rate of diffusion in this α brass at any temperature below the melting point, by means of either of 2 equations. The method used made it possible to eliminate any uncertainties concerning the variation of rates of diffusion with concentration, as well as those concerning the superficial area of a porous surface. The diffusion coefficients in $cm.^2/sec.$ were 8.6×10^{-11} at 600° C. and 28.3% Zn, 3.54×10^{-10} at 655° C. and 26.8% Zn, and 1.31×10^{-9} at 720° C. and 25.3% Zn. These rates of diffusion fit the generally accepted equation $D = Ae^{-Q/RT}$, which shows the effect of temperature on diffusion. The value of Q in this equation was found to be 39,000 cal./g.-atom. The substitution of any of the diffusion coefficients above in the empirical equation $D = (Q/Nh)\delta^2 e^{-Q/RT}$ gives a value Q of about 38,000 cal./g.-atom, which is in exceptional agreement with the value of Q above. JLG (9b)

X-ray Study of the Cobalt-sulfur System (Röntgenuntersuchung des Systems Co-S) D. LUNDQUIST & A. WESTGREN. *Z. anorg. allgem. Chem.,* Vol. 239, Aug. 12, 1938, pp. 85-88. X-ray diffraction research. A complete analysis of the system Co-S was undertaken to clear up some existing disagreements. The following compounds were confirmed: Co_9S_8, CoS, Co_3S_4 and CoS_2. For Co_9S_8, a cube edge of 9.907 A.U. was found. The compound CoS resembles FeS in that its lattice contracts on adding S, but to a much less extent; its structure, of the NiAs type, has the dimensions a = 3.367, c = 5.177 A.U. or a = 3.361, c = 5.160 A.U., depending on whether the phase is saturated with Co or S. The homogeneity range of CoS at 650° C. is from 51 to 53 atomic % S. No superstructure lines were found. All alloys in the range 54-66 atomic % S show lines of a phase Co_3S_4, which is face-centered cubic, a = 9.382 A.U. The structure of the compound CoS_2 was that found by DeJong and Willems, but with a slightly smaller parameter, a = 5.524 A.U. For earlier work see also *Metals and Alloys,* Vol. 8, May 1937, p. MA 296 R/7. HFK (9b)

The Growth of Magnesium Crystal in its Vapor. SEITA SAKUKI. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Oct. 1938, pp. 1131-1146. In English. Original research. Frequent reference is made to experiments by Straumanis (see *Metals and Alloys,* Vol. 3, May 1932, p. MA 126 R/2; Vol. 6, Apr. 1935, p. MA 164 R/2). The object of this study was to obtain Mg crystals as large as possible. The author studied the effect of temperature, pressure, time, Fe sheet carriers, asbestos wool, kind of gas (air, sulphurous acid, H) size of sublimation surface, longitudinal distribution of temperature, etc. Mg crystals grow most rapidly to a regular form in Mg vapor at the highest possible temperature (below the melting point) in the densest possible vapor and at a moderate reduction of pressure of 0.80-2.70 mm. Hg. X-ray investigation of the large crystals shows many crystals of mosaic structure. The large crystal faces had the indices of (0001) or (10-10). The crystal faces having the indices (10-11) were generally of small area. EF (9b)

The Rate of Viscous Flow of Metals: Part I, Tin. L. C. TYTE. *Proc. Physical Soc., London,* Vol. 50, Mar. 1938, pp. 153-175, discussion pp. 311-312. Research on wires. Determinations are reported of the "constant" rate of flow reached after 15-20 min. when loads up to 2,000 lbs./in.^{2} were applied to Sn wires (purity and grain size unspecified) at temperatures from 19° to 207° C. Exponential relationships between this "velocity of viscous flow," the stretching load and the absolute temperature are developed in detail. The results are held to confirm that the allotropic modification from β to γ Sn occurs at 203° C. rather than 161° C.; and that there is a transition in the nature of deformation from single to double glide at a stress which varies with temperatures according to a hyperbolic law. [The involved mathematical treatment would be more convincing if the experimental data were more complete. "Creep" tests carried out for 20 min. may be easy to observe but should not be extrapolated.—J. C. C.]

The Diffraction of X-rays by an Age-hardening Alloy of Aluminium and Copper. G. D. PRESTON. *Phil. Mag.,* Vol. 26, Nov. 1938, Suppl. pp. 855-871. Original research. The changes observed in the X-ray spectrum at different stages of age-hardening at room temperature and at 200° C. were sought to be related to the hardness of the metal. Photographs of the different stages are reproduced, and the structures are analyzed on this basis. The structure seems to be tetragonal with a = 5.71 A.U., c = 1.015 A.U., and contains 4 Cu and 8 Al atoms, *i.e.* 4 molecules of $CuAl_2$; this structure differs, however, from that of $CuAl_2$ as usually obtained. It could not be established whether this is a metastable intermediate phase or the stable form of $CuAl_2$ at low temperatures; the new crystals are closely united to the Al lattice.

Ha (9b)

An **X-ray Study of the Superlattice in Certain Alloys.** E. A. OWEN & I. G. EDMUNDS. *Proc. Roy. Soc. London,* Vol. 50, May 1938, pp. 389-397. Original research. The X-ray structure of 50:50 atomic % Ag-Zn alloys shows a strong ordered arrangement (superlattice) when a sample, quenched from above 300° C., is examined at room temperature. Strangely enough, when the sample is examined at 300° C. the superlattice is not found. This unexpected behavior is not shown by the Au-Zn alloys, which retain their superlattice at all temperatures up to the melting point. In the Ag-Zn alloys an ordered arrangement must exist at high temperatures, but it is of a type that cannot be detected by X-rays.

The Surface Structure of Liquid Mercury. G. L. J. BAILEY, S. FORDHAM & J. T. TYSON. *Proc. Physical Soc., London,* Vol. 50, Jan. 1938, pp. 63-69. Includes discussion. Original research. Electron diffraction measurements always show a thin crystalline film on the surface of liquid Hg. This, however, is not a Hg structure; it is due to a scum impurity which it has so far been impossible to eliminate. The surface film cannot be Hg, for it prevents evaporation in vacuum, protects an evaporated Au layer from attack until the skin is broken by agitating the Hg, and acts as a barrier against oxidation of Hg by ozone. JCC (9b)

3

The Chromium-phosphorus System (Untersuchungen im System Cr-P) H. NOWOTNY & E. HENGLEIN. *Z. anorg. allgem. Chem.,* Vol. 239, Aug. 12, 1938, pp. 14-16. Experimental. X-ray diffraction studies were made on the Cr-P system up to 50 atomic % P. Two compounds, Cr_3P and CrP, were found. Cr_3P, which is isomorphous to Fe_3P (group S_4^3), is tetragonal, a = 9.126 A.U., c = 4.560 A.U. It is weakly ferromagnetic. CrP is isomorphous to MnP (group D_{2h}^{16}) and has a NiAs structure, with a = 5.93, b = 5.35 and c = 3.12 A.U. It is non-ferromagnetic.

HFK (9b)

4

Crystal Structure of Ni_3S_2 (Die Kristallstruktur von Ni_3S_2) A. WESTGREN. *Z. anorg. allgem. Chem.,* Vol. 239, Aug. 12, 1938, pp. 82-84. Experimental. The crystal structure of Ni_3S_2 has been determined completely. It is rhombohedral, space group D_3^7, a = 4.041 A., α = 90.3° and thus almost cubic. The cell contains 1 Ni_3S_2 group, the S atoms occupying the positions of a body-centered cubic structure with the Ni atoms filling in at ½ y y, y ½ y and y y ½.

The Constitution of Aluminum-zinc Alloys of High Purity: The Nature of the Thermal Change at 443° C. MARIE L. V. GAYLER & E. G. SOUTHERLAND (Natl. Phys. Lab.) *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 813, 15 pp. Original research. The liquidus and solidus curves of high-purity Al-Zn alloys were redetermined over a range of composition of 40-100% Zn by weight. Thermal analyses of alloys stirred continuously show definitely that: (a) The heat change that occurs on heating takes place over a range of temperature; (b) the temperature at which maximum heat absorption occurs falls with increasing Zn content: and (c) on cooling, a heat evolution occurs at very nearly constant temperature. Microscopic analyses showed: (a) No primary separation along the liquidus between the melting point of Al and that of the eutectic, other than that of the Al solid solution; (b) no evidence of the existence of a 2-phase field above 360° C.; and (c) no evidence of a "reaction" compound. The heat change that occurs over the range of temperature 440-470° C. was shown to be due to a marked change—of about 12% Zn by weight—in the composition of the primary Al phase, which takes place during solidification over a very small temperature interval, approximately 12° C. A revised equilibrium diagram is given. JLG (9b)

X-ray Analysis of the System Arsenic-antimony (Röntgenanalyse des Systems Arsen-Antimon) W. TRZEBIATOWSKI & E. BRYAK. *Z. anorg. allgem. Chem.,* Vol. 238, July 1, 1938, pp. 255-267. Experimental. 20 vacuum-melted alloys of As-Sb and 2 natural alloys (Allemontite) were studied by X-ray diffraction after various heat treatments. A complete solid solution series exists at high temperatures, and also at low temperatures in the range 0-25 atomic % As. In the range 25-46 3 atomic % As a new phase (β) was observed that has a face-centered cubic structure with possibly either $a_0 = 5.54$ A.U. or 11.06 A.U. The β-phase transforms to the solid solution on tempering at 550° C. Of the natural alloys, 1 containing 53.3 atomic % As showed a homogeneous solid solution, but the other containing 71.4 atomic % As showed 2 solid solution phases not in equilibrium. HFK (9b)

The Ternary Alloys of Cobalt-manganese-copper (Das Dreistoffsystem Kobalt-Mangan-Kupfer) W. KÖSTER & E. WAGNER. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 352-353. Experimental. The alloys of Co-Mn-Cu containing up to 40% Mn were examined by thermal and magnetic methods. The 2-phase field in the Co-Cu system is not closed in this composition range, so homogeneous ferromagnetic alloys do not occur. GD (9b)

The Magnetic Susceptibility of the Alloys of Zinc with Nickel, Cobalt and Iron (Die magnetische Susceptibilität der Systeme des Zinks mit Nickel, Kobalt und Eisen) J. SCHRAMM. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 327-334. Experimental. Magnetic susceptibility measurements were made on powder samples of various binary alloys with the following results: *Nickel-Zinc.* The reactions $\delta \rightleftarrows \Gamma + M$ (melt), 490° C.; $M \rightarrow \beta + \Gamma$, 875° C.; $\alpha + M \rightarrow \beta$, 1040° C.; $\beta_1 + \Gamma \rightleftarrows \beta$, 675° C.; $\beta_1 \rightleftarrows \alpha + \beta$, 810° C.; $\beta_1 \rightleftarrows \beta$ all gave sharp breaks in the temperature-susceptibility curves, but $\delta + \eta \rightleftarrows M$, 419° C., and $\Gamma_1 \rightleftarrows \Gamma + \beta_1$ (about 500° C.), Zn (melt) $\rightleftarrows$ Zn (solid) and $\Gamma \rightleftarrows \Gamma_1$ could not be detected. The following phase boundaries were established: $\delta - (\delta + \eta)$ at 10% Ni from 0° to 400° C.; $\Gamma - (\Gamma + \Gamma_1)$ and $\Gamma_1 - (\Gamma + \Gamma_1)$ at about 20% Ni; $\beta_1 - (\beta_1 + \Gamma_1)$ and $\beta_1 - (\beta_1 + \Gamma)$ at 45.5% Ni from 0° to 675° C.; $\beta_1 - (\alpha + \beta_1)$ at 52% Ni from 0° to 750° C.; $\beta - (\alpha + \beta)$ at 50% Ni above 850° C. The isotherms of the Γ alloys show a minimum between 15% and 17% Ni. *Cobalt-Zinc, (0-15% Co).* The reactions $\zeta \rightleftarrows \delta_1 + M$ 566° C.; $\delta_1 + M \rightleftarrows \delta$, 675° C.; $\delta_1 \rightleftarrows \delta + \Gamma$, 690° C.; $\delta \rightleftarrows \Gamma + M$, 746° C.; and $\delta_1 \rightleftarrows \delta$ were observed and the ζ phase has a minimum in the susceptibility values. *Iron-Zinc, (0-28% Fe).* All known three-phase reactions were observed and the following phase limits established: $\delta_1 - (\zeta + \delta_1)$ at 7% Fe from 0 to 530° C.; $\delta_1 - (\Gamma + \delta_1)$ at 11.5% Fe from 0 to 600° C.; and $\Gamma - (\alpha + \Gamma)$ at 28% Fe from 0 to 700° C. GD(9b)

Some Consequences of Degassing Metals at Ordinary Temperatures (Quelques Conséquences du Procédé de Dégazage des Métaux à la Température Ordinaire) GEORGES CHAUDRON, ALBERT PORTEVIN & LÉON MOREAU. *Comp. Rend.,* Vol. 207, July 18, 1938. pp. 235-237. Original research. The variation in the lattice parameter of the metals Pd and Ta was measured during degassing of the samples by ionic bombardment *in vacuo* at ordinary temperatures. This method is more effective in extracting H_2 than heating the sample in vacuo. Increases in the parameter, electrical resistivity and hardness due to the presence of H_2 are as follows:

Metal	Parameter a_0 (A.U.) Varies	Increase in Resistivity	Increase in Hardness
Pd (α)	3.882 to 4.020	69%	48%
Pd (β)	3.882 to 3.885	45%	266%
Ta	3.296 to 3.302	—	—

FHC (9b)

X-ray Studies on Cobalt-tungsten Alloys (Röntgenuntersuchung von Kobalt-Wolframlegierungen) A. MAGNELI & A. WESTGREN. *Z. anorg. allgem. Chem.,* Vol. 238, July 1, 1938, pp. 268-272. Experimental. The crystal structures of 2 phases in the Co-W system, Co_3W and Co_7W_6 were determined. Co_3W is hexagonal with $a_0 = 5.120$, $c = 4.120$ A.U. The atomic arrangement is the same as in Mg_3Cd, *i.e.* a superstructure of hexagonal close packed spheres. Co_7W_6 is rhombohedral with dimensions $a_0 = 8.92$ A.U., $\alpha = 30° 42'$; or $a_0 = 8.99$ A.U., $\alpha = 30° 40'$, depending on whether the phase is saturated with Co or W. The atomic arrangement of Co_7W_6 is the same as that of Fe_7W_6 and Fe_7Mo_6. HFK (9b)

Compounds of Titanium with Phosphorus. Contributions to the Systematic Affinity Theory No. 83 (Ueber die Verbindungsfähigkeit von Titan mit Phosphor. Beiträge zur systematischen Verwandschaftslehre. 83) W. BILTZ, A. RINK & F. WIECHMANN. *Z. anorg. allgem. Chem.,* Vol. 238, Aug. 2, 1938, pp. 395-405. Experimental. Contrary to earlier objections, it was found possible by 2 different methods to synthesize a monophosphide of Ti having the formula $TiP_{0.94}$, which is gray and metallic in appearance and has a characteristic X-ray pattern different from that of its analogue SiP. The compound is thermally stable even at 1000° C. X-ray patterns for preparations between Ti and TiP indicate the possible existence of a metallic appearing compound Ti_3P. HFK (9b)

The Cobalt Corner of the Iron-cobalt-vanadium System (Die Kobaltecke des Systems Eisen-Kobalt-Vanadin) W. KÖSTER & K. LANG. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 350-352. Experimental. Sections were studied that ran through the Co corner and contained ratios of Fe to V of 1:19, 1:4, 7:13, 1:1, 13:7, and 4:1. The solid solution of γ Co extends from 69 to 45% Co over this range. Curie temperatures and the $\gamma \rightleftarrows \epsilon$ transformations were determined, as well as the Brinell hardness of the alloys. GD (9b)

The Structure of Electrically Polished Copper Surfaces (Ueber die Struktur elektrisch polierter Kupferoberflächen) K. H. MOORE. *Ann. Physik,* Ser. 5, Vol. 33, Sept. 1938, pp. 133-137. The surface of an electrolytically polished Cu piece (as described by Lowery and Jaquet) was examined with electron diffraction and found to consist of little lamina of Cu_2O; these leaves or lamina are connected on dodecahedron planes. Only one orientation exists in which the edges of the cube of Cu_2O are parallel to the edges of the Cu cube. Ha (9b)

Some Ternary Systems of Aluminum (Ueber einige Dreistoffsysteme des Aluminiums) H. HANEMANN &. A. SCHRADER. *Aluminium,* Vol. 20, Nov. 1938, pp. 771-774. Investigations were made of some ternary Al alloys, either to establish diagrams previously unknown or to correct inaccuracies in known ones. In the system Al-Fe-Mg, only the 3 crystal types Al (α), Al_3Fe and β (Al_3Mg_2) occur; no peritectic reaction was found. A ternary eutectic of α, β and Al_3Fe was found in many alloys consisting of 68% Al, 3% Fe, 29% Mg at 445° C., and a 2-phase alloy of Al_3Fe and β. The α-solid solutions have a tendency to crystal segregation. In the system Al-Mg-Mn, a ternary eutectic at 437° with 71.25% Al, 26.40% Mg and 2.35% Mn was established with the crystal types Al (α), Al_3Mg_2 (β) and Al_4Mn; the latter is easily recognizable by etching and by its behavior in polarized light. Although a peritectic reaction does not take place, a phase transformation Al_6Mn-Al_4Mn was observed, which is explained by the assumed existence of a metastable system with Al_4Mn and a stable system with Al_6Mn and Al_4Mn. Alloys with low Mg contents crystallize in the stable equilibrium, with high Mg contents in the metastable equilibrium. The system Al-Mn-Si has a ternary eutectic of 86.8% Al, 12% Si and 1.2% Mn at 575.5° C. with 3 ternary crystal types T, X and Y. T contains about 40% Mn and 15% Si and can absorb Mg and Si in solid solution. X is probably a ternary solid solution of the Al_6Mn phase. Homogeneous Y was found at 14-15% Si and 1-2% Mn. The 3 types are easily distinguishable by their etched sections and behavior in polarized light; X transforms peritectically into T and Al_6Mn. The diagrams of these 3 systems were constructed from these observations. Ha (9b)

X-ray Study of Heating an Al-Mg Solid Solution (Étude par Rayons X du Revenu de la Solution Solide Aluminium-Magnésium) PAUL LACOMBE & GEORGES CHAUDRON. *Compt. Rend.,* Vol. 207, Nov. 7, 1938, pp. 860-862. Original research. The authors show by X-ray studies the time of heating at 200° C. as a function of the change in parameter of a series of Al-Mg solid solution alloys containing 9, 11, 12 and 13.5% Mg, respectively. The alloys containing 12 and 13.5% Mg, on being heated 6 min. at 200° C., show an increase in lattice parameter from 4.1028 to 4.1064 A.U. for the former alloy, and from 4.1113 to 4.1158 A.U. for the latter alloy. Further heating causes the lattice parameter to decrease. The authors claim the increase in size is due to certain Mg atoms taking preferred positions on the lattice of the solid solution. FHC (9b)

Irregular Breaks of Dilatometric Curves in Cu-Al Alloys in the Region of 12% Al (Sur les Anomalies Dilatométriques Irrégulières dans les Alliages Cuivre-Aluminium à environ 12 pour 100 d'Aluminium) ANDRÉ BOUTILLIER. *Compt. Rend.,* Vol. 207, Sept. 19, 1938, pp. 498-500. Original research. A Cu-Al alloy with 12% Al was heated above 580° C. to form β solid solution. Cooled rapidly, the sample showed a break in the dilatometric curve corresponding to an increase in length beginning at 365° C. and ending at 300°-280° C., called transformation T_r. On being reheated to 450° C., a contraction took place at 400°-450° C., called transformation T_c. Again on being cooled, T_r occurred at 370°-280° C. Another 12% Al-Cu alloy, heated above 580° C. to form β, was then cooled slowly. At 365° C. (T_r), a contraction took place and thermal cycles up to 450° C. showed an elongation at 400° C. (T_c). Not only did the speed of formation of the constituents involved cause a change in contraction or expansion of the sample at T_r and T_c, but dimensions of the sample and slight variations of composition in the same sample were also effective. FHC (9b)

Effect of Cold Deformation on the Values of Crystal Lattice Constants. B. M. ROVINSKIY. *Zhur. eksp. i teor. fiz.,* Vol. 8, Jan. 1938, pp. 96-99. In Russian. Original research. Powdered samples of cold-rolled and of annealed Cu, mixed with annealed Al powder as calibrating substance, were investigated by the X-ray powder method, using Cu radiation in a camera of 114.6 mm. diameter. The X-ray spectrograms were photometered with a Zeiss recording microphotometer. A comparison of the intensity of the X-ray diffraction lines of the samples failed, within an error of 0.002 A.U., to disclose any change in the lattice constants of Cu due to cold deformation. The causes of the disagreement of this finding with that of Wood (see *Metals and Alloys,* Vol. 6, Jan. 1935, p. MA 26) are discussed. ORS (9b)

The Alloys of Cobalt with Boron, Arsenic, Zirconium, Columbium and Tantalum (Die Systeme des Kobalts mit Bor, Arsen, Zirkon, Niob und Tantal) W. KÖSTER & W. MULFINGER. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 348-350. Experimental. The Co-rich sections of the binary alloys of this metal with B, As, Zr, Cb and Ta were explored over a range that included the first eutectic in each system. The phases Co_2B, Co_4Zr, Co_3Cb_2 and Co_5Ta_2 were established, the first 2 being ferromagnetic. The diagrams include the Curie temperatures and the transformations in the terminal Co solid solutions. The Cb and Ta alloys showed appreciable aging when annealed at 800° C. GD (9b)

Cobalt and Its Alloys. Application in Mechanical and Electrical Industries (Le Cobalt et ses Alliages. Leurs Applications dans les Industries Méchaniques et Électriques) J. CHALLANSONNET. *Tech. Moderne,* Vol. 30, Aug. 1938, pp. 539-541. Comprehensive review. A French valve steel contains 0.95% C, 18% Cr, 2% Co, 1% Mo. Co is used in various magnet steels: KS type with 0.4-1% C, 36% Co, 1.5-3% Cr, 5-9% W ($B_r = 9000$; $H_c = 270$); Koester type with 17% W added to Fe_2Co and optional Mo content ($B_r = 9600$; $H_c = 149$); and Mishima type with 25-35% Co, 10-25% Ni, 8-25% Al or Ti, balance Fe ($H_c = 1000$ for Ti grade). Co-Ni alloys are used as regulators. Co-Cr alloys are the basis of Stellite. Co-Si compounds are resistant to halogens, but very difficult to make. Co-Be alloys (around 4% Be) are age hardening. The addition of Co to Cu retards softening on annealing. Cu-Be-Co alloys are used in electrical industry. See also *Metals and Alloys,* Vol. 10, Jan. 1939, p. MA 53L/5. JZB (10)

Non-ferrous Metals at the Motor Show. Increasing Use of Aluminum Alloys of all Forms. *Metal Ind., London,* Vol. 53, Oct. 21, 1938, pp. 387-388. Discussion of metallurgical developments as revealed at a British auto show. Brass as the main structural material for radiator shells is being superseded by Cr-plated steel and die-cast Zn-base alloys. The Al-alloy cylinder head and piston are now standard in a number of cars. Al alloys are also used in rocker covers, crankcases, sump, differential unit housing, steering box and the like. Zn-base alloy pressure castings are used for small components such as carburetor bodies, cover plates, etc. Both Alfa-Romeo and Lea-Francis exhibited models panelled with Al sheet. Normal practice is to use white metal bearings for passenger cars and Pb-bronze for heavy duty work. RWB (10)

Contributions of Metallurgy to Engineering Progress. W. R. BARCLAY. *Mech. Eng.,* Vol. 60, Aug. 1938, pp. 595-600; Sept. 1938, pp. 687-695. Excellent general summary and appraisal of the progress due to developments of new alloys, use of new metals and working processes for ferrous and non-ferrous metals. Topics discussed include: Alloy steels, high speed steels, corrosion- and heat-resisting steels, non-ferrous metals and alloys, Ni-Cu, Monel and related alloys, Ni-Cr and special Ni-containing alloys, Al and light alloys, Mg alloys, die-casting alloys, pure metals, powder metallurgy, Sn, Pb and Cu alloys and current research. Many tables of properties are included. 28 references. Ha + FPP (10)

Liners Absorb the Wear. F. E. GOODING. *Steel,* Vol. 103, Sept. 12, 1938, pp. 40, 42, 70. Description of a Rex Pumpcrete for pumping concrete and of the ferrous metals used in its construction. Piston is cast Fe with 2% Ni, hardened to 335 Brinell, and ground to finished diameter. To resist abrasion, inlet and outlet valves and replaceable liners for pump cylinder and valve chamber are made of hardened S.A.E. 6145 steel, containing 0.40-0.50% C, 0.60-0.90% Mn, 0.80-1.10% Cr and 0.15-0.18% V. Liners are made by forming 2 flat plates to a semi-circular shape and welding together. These are hardened to full thickness by a single oil quench and draw, and then ground on outside to finished diameter. Curved parts of chamber are hard surfaced with No. 1 Stellite. MS (10a)

Magnetic Shields. W. B. ELLWOOD (Bell Labs.) *Bell Lab. Record,* Vol. 17, Nov. 1938, pp. 93-96. Review. Shields are used to protect electrical and magnetic equipment from stray magnetic fields. In a single shell, the shielding is proportional to permeability; in multiple shells, it is roughly a function of μ^n where n = number of shells. 3.8% Mo permalloy is best where a small field is to be shielded. For intermediate fields up to 5 gauss, perminvar is recommended; whereas for high fields, the 50:50 Fe:Co is most satisfactory. JZB (10a)

Aluminum as an Alloying Element in Steel (Aluminium als Legierungselement im Stahl) R. SCHERER. *Aluminium,* Vol. 20, Oct. 1938, pp. 682-687. Review. Al steels are divided into 3 groups: Pearlitic (with transformation), semiferritic and purely ferritic. Al represses the magnetic transformation and raises the Ac_1 transformation. Alloys with up to 5% Al can be worked cold, but alloys with 5-15% are very brittle and can only be worked hot, and then with difficulty. The most important fields of application now are nitriding steels, heat-resisting steels (or better, irons) and permanent magnet alloys. Nitriding steels provide high surface hardness with good depth of penetration, even with a low Al content; some types contain 0.20% Mo as well as the customary 1% Al. A nitriding steel containing 1.1% Al, 0.20% Mo and 1.8% Ni is employed for highly-stressed parts, as Ni gives a more uniformly nitrided steel. Al, in amounts from 0.6 to 5.0% is a very important constituent of several corrosion and heat resisting low-C Fe-Cr, Fe-Cr-Si and Fe-Cr-Co alloys. Alloys with 2-5% Al and more than 20% Cr resist oxidation at 1200°-1350° C. Increasing Al content increases heat-resistance but lowers acid-resistance. The most commonly used alloys for permanent magnets are given in the table:

	Composition				Remanence, B_r	Coercive force, H_c	(BH)
Alloy	Co	Ni	Al	Ti	gauss	oersteds	max. $\times 10^{-6}$
Ni-Al		16-18	9-12		7700-8800	170-140	570-630
Ni-Al		19-21	9-12		7500-8800	230-180	700-800
Ni-Al-Co .	2.4	19-21	9-12		7500-8800	300-250	900-1100
Ni-Al		24-30	12-15		6000-7000	575-475	1050-1300
Ni Al-Co .	4.8	24-28	12-15		5600-6600	725-600	1300-1450
Co-Ni-Ti-Al	32	16-17	4-5	9-10	5800-6300	800-750	1500-1700

These alloys are particularly valuable because of their magnetic stability up to 100° C. 16 references. Ha (10a)

Drift of Magnetic Permeability at Low Inductions after Demagnetization. G. R. PATTERSON (Carnegie Inst. Tech.) *J. Applied Phys.,* Vol. 9, Oct. 1938, pp. 646-653. Experimental. The observed drift in permeability of medium-Si steel at low flux densities is not due to errors in method but to the material itself. Permeabilities were carefully measured on an Epstein apparatus, meeting A. S. T. M. specifications, which is described in detail. After demagnetization from B = 10,000 gauss, permeability measurements at B = 10 g. showed a decrease of permeability with time in which 60% of the change in 24 hrs. took place in the first hr. This effect increased with the Si content, being greatest at 4.5% Si. On varying the test flux density, the greatest drift occurred at B = 5 g. and then gradually decreased to 25 g. For a steel of medium Si content tested at 10 gauss over 24 hrs., the decrease in permeability ranges from 5 to 15%. Possible explanations, including aging, are discussed. HFK (10a)

Cast Iron Research and the Gas Industry. J. G. PEARCE. *Inst. Gas Engrs. Communication* No. 183, June 1938, 26 pp.; *Foundry Trade J.,* Vol. 59, Sept. 15, 1938, pp. 199-201; Sept. 22, 1938, pp. 216-217. Review. The developments in cast Fe metallurgy and production of interest to the gas industry are reviewed. The uses of cast Fe in manufacture of gas and coke, in gas distribution and in gas utilization are surveyed. The properties of various grades of cast Fe, particularly in regard to mechanical strength and resistance to heat, corrosion, wear and erosion are surveyed. Cast-Fe alloys interest the gas engineer from 4 service aspects involving mechanical strength, heat resistance, corrosion resistance and wear or erosion-resistance. Mechanical strength, malleable cast Fe, gray Fe, fully-pearlitic irons, high-duty irons, heat-treated cast Fe, heat resistance, effects of thermal shock, corrosion resistance, wear-resistance, centrifugal castings, enamelling, etc., are discussed. AHE + AIK (10a)

Steel Construction at the New York World's Fair. JOHN PHILIP HOGAN. *Iron Age,* Vol. 142, Nov. 10, 1938, pp. 36-39. Practical description. General type of construction consists of steel frame and wooden studding covered with gypsum board. Over this is placed steel mesh. With the exception of the important structures, the steel is light, about 500 lb. to the piece. Stainless steel is also being used. Total estimated amount of steel and Fe to be used is 64,100 tons. VSP (10a)

Chromium Cast Irons. E. K. SMITH (Electro Metallurgical Co.) *Metal Progress,* Vol. 34, Nov. 1938, pp. 563-568. Descriptive. With more than 1% Cr (an element which causes the formation of carbides in cast irons and of more and finer pearlite), it is necessary in castings of thin sections to add a graphitizing element, such as Ni or Cu, to the melt. In a series of tests poured at constant temperature and varying amounts of from 0.04 to 2.18% Cr (the ferro-chrome added had the same C content as that of the gray cupola Fe) the combined C and transverse strength increased to a maximum at 0.50% Cr. The tensile and compressive strength increased throughout the entire range. Cr increases the impact resistance of cast Fe up to the point where carbides begin to appear in the microstructure (0.77% Cr in this case). This condition depends upon the section size, composition of the base metal, and the cooling conditions. With large section size and high Si and Mn, large amounts of Cr can be added without production of excessive hardness. The addition of 0.77% Cr raised the Brinell hardness to 207, but no difficulty was encountered in machining a bar containing 1.36% Cr that tested 241 Brinell. Cr irons have high wear resistance and are used for many articles subjected to severe abrasion. The analyses of 18 different Cr irons are given. The properties of Cr irons from 12% Cr to 34% Cr are also listed. At least 12% Cr is necessary in solid solution to confer corrosion resistance. If Si is present in excess of 2%, it interferes with the heat treatment and also slightly increases the as-cast hardness. The heat treatments of several Cr irons are mentioned. 6 references. CWH (10a)

The Effect of Alloying Additions on the Resistance of Steel to Hydrogen under High Pressure (Der Einfluss von Legierungszusätzen auf die Beständigkeit von Stahl gegen Wasserstoff unter Hohem Druck) F. K. NAUMANN. *Stahl u. Eisen,* Vol. 58, Nov. 3, 1938, pp. 1239-1250. Research. Alloying additions were made to a low-C steel and tensile tests made at room temperature after exposure to 300 atm. of H_2 for 100 hrs. at temperatures up to 600° C. After exposure at 400° C., the reduction of area began to fall rapidly, due to intergranular attack by the H_2. The elements that do not form carbides, such as Si, Ni and Cu, did not change the resistance to H_2 attack. Mn, which does not form a special carbide but goes into solution to some extent in Fe_3C, increased the resistance slightly. Cr, W and Mo gave a decided increase in resistance. These elements stabilize the carbides. When enough Cr was present to form the compound $(Cr, Fe)_7 C_3$, the resistance was further increased. Even these steels were slightly decarburized but with little effect in reducing the ductility. The effects of V, Ti, Zr and Cb were somewhat weaker than W and Mo, except when rather high amounts, up to 2-3%, were present, when they decidedly increased the resistance. This is attributed to the substitution of very stable special carbides for Fe_3C. For work on unalloyed steel, see *Metals and Alloys,* Vol. 9, Jan. 1938, p. MA 45 L/7. SE (10a)

Alloy **Steels for Modern Still Tubes.** R. L. WILSON (Climax Molybdenum Co.) *National Petroleum News,* Vol. 30, Mar. 23, 1938, pp. R-132, 134-138. Describes the comparative effect of the various useful alloying elements on the corrosion, oxidation, high temperature strength, and air-hardening of refinery tube steels. Many of the newer compositions are classified according to their serviceability, and the latest creep data are tabulated for some of the types. Small amount of Cr, as low as 2-2.5%, make extraordinary improvement in corrosion resistance. From that range to 6%, the rate of corrosion reduction is nearly linear. Si without Cr does not increase corrosion resistance, but is beneficial when accompanying Cr. Si reduces oxidation and scaling tendencies. Oxidation is retarded especially by the addition of Ti, W, Cb and Al; W especially is added for strength. Ti and Cb prevent air-hardening of Cr alloys. A list of 14 new alloys that offer good properties for specific purposes is included, along with their compositions and special properties; this is a very useful list to the refiner. 7 references. VVK (10a)

Thermal Conductivity of Iron and Steel. *Metallurgist (Suppl. Engineer),* Aug. 1938, pp. 152-154. Correlated abstract of 9 references. The recent work of Esser, Eilender and Pütz is checked against earlier investigations by others. The results of the German authors are higher than those of earlier workers, fully confirming the upward trend of recent determinations. The pronounced effect of the last few hundredths of a per cent of impurities on thermal conductivity is graphically shown by the steepness of the thermal conductivity-C content curves as they approach zero C. The austenitic steels had a distinctly lower thermal conductivity than the other classes examined and showed a slight increase in conductivity with rise in temperature; the latter, however, was less than that observed by others. Over the whole series of irons and plain-C and alloy steels, those with a conductivity more than 0.06 c.g.s. units showed a drop in conductivity towards that value as the temperature increased, while those with a lower conductivity showed a rise. The effect of the higher temperatures used in hardening and tempering still awaits investigation.

OFHC

OXYGEN FREE HIGH CONDUCTIVITY

A Superior Copper

FOR ALL PURPOSES

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.

OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Influence of Titanium and Molybdenum on the Magnetic Properties of Fe-Ni-Al Alloys. FESZCZENCKO-CZOPIWSKI & L. KOSLOWSKI. *Foundry Trade J.,* Vol. 59, Oct. 27, 1938, pp. 305-306. Original research. More than 210 sand-cast specimens were prepared. They were of the following dimensions: 18 x 18 x 103 mm.; 18 x 9 x 103 mm.; 18 x 6 x 103 mm.; 25 x 12 x 103 mm.; 25 x 6 x 103 mm. and 18 x 12 x 103 mm. The compositions of the castings were:

Castings	C	Si	Mn	S	P	Ni	Al	Ti	Mo	Cu
a	0.05	0.45	0.15	0.008	0.008	27.16	12.03	...	...	0.045
b	0.05	0.38	0.22	0.009	0.009	28.36	10.35	0.98	...	0.149
c	0.05	0.22	0.25	0.011	0.013	27.92	9.79	2.16	...	0.218
d	0.05	0.24	0.16	0.007	0.011	28.31	10.87	...	2.05	0.126

An apparatus of the Hartmann-Braun type was used in studying the magnetic properties. The following conclusions were drawn: (1) The coercive force H_c and the residual magnetism B_r of castings, a, b and d increased with the decrease of the section. The reverse phenomenon was observed with castings c. (2) The most effective heat-treatment for producing the maximum values of H_c and B_r in the castings a, b and c was oil quench from 1200°-1250° C., followed by 2-hr. tempering at 650° C. (3) The addition of 1-2% Ti increased H_c and B_r of Fe-Al-Ni alloy, provided that castings were subjected to the above-mentioned thermal treatment. (4) An addition of Mo had a deleterious effect on magnetic properties on specimens in "as-cast" condition. These alloys should be water quenched from 1200°-1250° C. and tempered for 1-2 hrs. at 650° C. AIK (10a)

A Magnetic Balance for Saturation Measurements. The Saturation Values of Cementite and C Steels as Function of Temperature and Previous Treatment (Eine magnetische Waage für Sättigungsmessungen. Die Sättigungswerte von Zementit und Kohlenstoffstählen in Abhängigkeit von Temperatur und Vorbehandlung) H. LANGE & K. MATHIEU. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch., Düsseldorf,* Vol. 20, No. 18, 1938, pp. 239-246. Description of the principle and construction of a magnetic balance that permits the determination of magnetic saturation as a function of temperature and the observation of transformation processes by measuring the force exerted on a sensitive balance by the sample in the electromagnet at different temperatures. An example of carburization of a piece of Fe by benzol vapors is described to show how the specific saturation of cementite can be exactly determined. The manner of calculation is explained. 10 references. Ha (10a)

Nickel in the Railroad Field. A. L. ROBERTS. *Southern & Southwestern Railway Club Proc.*, Vol. 26, July 1938, pp. 10-30. Descriptive survey. After a general survey of the use of Ni in steels, especially those employed in railroad operation, a recently developed alloy steel (Yoloy) of 0.06-0.25% C, 0.4-0.8% Mn, 0.04% max. P, 0.05% max. S, 1.75-2% Ni, 0.90-1.10% Cu, is described as particularly suitable for car construction. Low-C grade is employed where heavy forming or welding, or both, are to be done; medium-C, for less severe forming; and high C, where no forming is done. Tensile strength is 65,000-95,000 lbs./in.^{2}, yield point 70% of tensile strength, elongation in 8 in. 1,800,000/ tensile strength. Impact value for low-C grade is above 50, for medium-C 40-50, for high-C under 35. The Mn content is 0.4-0.6% for 0.06-0.12% C, 0.5-0.7% for 0.12-0.17% C, and 0.6-0.8 for 0.17-0.25% C. A special field of application is in gasoline and oil tank trucks. Ha (10a)

The Development of High Strength Structural Steels (Die Entwicklung der hochfesten Stähle für den Grosstahlbau) P. HOFF. *Stahl u. Eisen*, Vol. 58, Sept. 29, 1938, pp. 1053-1057. Review. The German structural steels are classified according to tensile strength—St 37, of 37-45 kg./mm.^{2} (52,000-64,000 lbs./in.^{2}); St 48, of 45-58 kg./mm.^{2} (64,000-82,000 lbs./in.^{2}); St 52, of 52-62 kg./mm.^{2} (74,000-88,000 lbs./in.^{2}). Up to 1900, St 37, a 0.12% C steel, was used almost universally. As the demand arose for a stronger steel, a higher yield strength rather than a higher tensile strength was recognized as the main desideratum. However, after somewhat unsatisfactory experiences with expensive Ni and Ni-Cr steels, a plain C steel was used in 1924—St 52 with 0.30% C. Somewhat later Si additions were made. After experience with these steels, St 52 with 0.2% C, 0.5% Si, 1.2% Mn and 0.06-0.1% P was put on the market in 1928. This has high yield strength and, what is most important, is easily weldable. SE (10a)

Effects of Firing on the Steel of Cannon (Les Alterations de l'Acier des Canons Uses par le Tir) E. PIANTANIDA. *Mem. Artillerie Francaise*, Vol. 17, No. 1, 1938, pp. 137-152. Original research. Metallographic evidence shows that erosion of gun barrels is not caused by carburizing or nitriding of surface layers but by heat checking, as postulated by Tschernoff. No chemical alteration of the steel was noted. Surface layers were martensitic. Results compared favorably with author's work on guns of wartime manufacture. A cold-worked barrel (0.41 C, 0.31 Mn, 0.13 Si, 0.022 S, 0.022 P, 0.67 Cr, 2.12 Ni, 0.10 Mo, and 0.19 V) fired 494 rounds with initial velocities about 1000 meters per sec. A barrel not cold worked (0.31 C, 0.47 Mn, 0.17 Si, 0.007 S, 0.022 P, 0.61 Cr, and 2.57 Ni) fired 413 rounds at same initial velocities. Effect of cold working on erosion was not given. DJM (10a)

A. J. PHILLIPS, SECTION EDITOR

The Importance of Lanthanum as a Useful Material (Ueber die Bedeutung des Lanthans als Werkstoff) E. ARNDT & K. E. PÜTTER. *Angew. Chem.*, Vol. 51, July 9, 1938, pp. 463-464. Review. Lanthanum oxide is contained in fairly large percentages in monazite sands used for the manufacture of Th and incandescent gas mantles. La metal (atomic weight 138.9) has a specific gravity of 6.2 and a melting point of 810° C., tarnishes in air and behaves generally like Ca. La oxide and hydroxide are completely converted in air to La carbonate. Possible uses in ceramics are suggested. Some constitutional diagrams have been established of alloys of La with Pb, Sn, Tl, Ag, Cu and Au. La might also find some use as a catalyst. 14 references. Ha (10b)

Copper-chromium Alloys. M. G. CORSON. *Iron Age*, Vol. 142, Oct. 13, 1938, pp. 78, 80-81; Oct. 20, 1938, pp. 25-28. Original research. Gives historical data on Cu-Cr alloys and describes large experimental castings made for the study of the physical properties of the alloys, both in as-cast and heat-treated conditions. Discusses experimental results obtained. Detailed variations of physical characteristics throughout the castings are given in tabulated form. Shrinkage phenomena can be avoided by the addition of a small amount of Si to Cu-Cr. Cu-Cr castings in heat treated state have a proportional limit of at least 19,000 lb./in.^{2} and can be safely loaded to 17,000 lb. fiber stress. VSP (10b)

Microhardness of Bearing Alloys. L. L. SWIFT (Cleveland Graphite Bronze Co.) *Metals Tech.*, Vol. 5, Sept. 1938, T. P. 966, 12 pp. Original research. Hardness as determined by the microcharacter and methods of making such hardness tests are discussed. Microhardness values for most of the phases found in bearing materials are given. Micrographs of the scratches in several alloys are shown. Significance of the hardness of different constituents in a bearing metal is discussed. The relationship between hardness and wear is indefinite. JLG (10b)

Light Metal Bearing Surfaces (Leichtmetall-Gleitflächen) P. SOMMER. *Maschinenbau Betrieb*, Vol. 17, Nov. 1938, pp. 579-582. Interesting survey and research. The behavior of sliding surfaces from the metallurgical point of view depends on the quality of machining and the character of the material. The smoothness and accuracy of the surfaces are to a great extent independent of the internal properties of the material if proper machining procedure is used. Relationship between surface and structure of light metals are studied in the cast, die cast, diamond cut and polished condition. Pistons are machined in a direction normal to that of sliding-in operation, this is why rubbing-off occurs during running-in period. Heat treated Al-Si and Al-Cu alloys (as used for pistons) do not possess good emergency running properties in case of critically poor lubrication. Anodic oxidation helps, as this coat improves adhesion of the oil film; it does not, however, induce better wear or lower the friction. Another method is to cover the surface with a very thin layer of soft metal (Babbit), which is squeezed out at highly stressed zones thereby better distributing the stress. The soft metal layer imparts to the new Al surface the ability to attain the desired surface quality quicker than by rubbing-off. The influence of structure on the bearing properties often depends on how the structure is affected by running-in, and particularly on the presence of crystals that differ in hardness from the matrix. The graphite flakes of cast Fe spread out and protect the metal. At low loads with good lubrication the Al alloy surface is smooth but dull. When load increases, the surface becomes shiny, the oil adhesion becomes worse. At still higher loads the surface turns dark, finally black. In this condition higher friction and tendency for "seizing" exist. There seems to be a relation between metal structure and tendency to galling. Materials with heterogeneous, fine and uniform structure are better; local overstress is less harmful. Materials with essentially tough and strong matrix and low percentage of hard "bearing" crystals seize more easily. Also, alloys which contain a great many hard and brittle crystals are subject to seizing; in this case no welding but splintering and jamming of hard particles occurs. A running surface that once seized will not give good service even if it appears intact. In order to clarify the problem of sliding friction, running-in tests were made. Some metals never assume a definite "run-in" condition. The friction of run-in surfaces may change during operation, when the pressure is varied. Some heterogeneous structures seem to show elastic effects so that the carrying and non-carrying constituents move against each other after relieving stress so as to assume a new equilibrium. Some alloys, upon reaching a critical temperature range, change their equilibrium of solution or recrystallization, which effect may reflect upon surface condition and friction. The wear resistance of cylinder cast iron is better than Al-Si (16-27% Si); then come Al-Si (11-14% Si), Al-Cu and Mg. Wear resistance of light alloys is nearly the same in soft and hardened state. Therefore, that part of the structure that is not changed by heat treatment seems to be the controlling factor. RPS (10b)

The Mechanical Properties of Various Copper Alloys at Room Temperature (Sur les Propriétés Mécaniques de quelques Alliages du Cuivre à la température Ordinaire) W. BRONIEWSKI. *Rev. Mét.*, Vol. 35, Aug. 1938, pp. 333-349; Sept. 1938, pp. 385-397. Review plus original research. To compare published elongation values obtained on various size specimens, it is necessary to separate the % elongation into uniform elongation and non-uniform elongation due to contraction at the point of fracture, and to calculate the "work to rupture" according to a formula, given in the text. A compilation of published data on the phase diagrams and mechanical properties, including work to rupture of the alloys of Cu with O, S, Ni, Mn, Zn, Sn, Ag, Au and Al (86-100 wt. % Al), is given, including the effect of heat treatment on the Sn, Ag, Au and Al alloys, and the effect of cold work on the Zn, Sn and Ag alloys. New data are presented for the Cu-Si alloys (up to 6 wt. % Si), and for the Cu-Al alloys (up to 13 wt. % Al). Finally, the age hardening of Al by Al_2Cu, Mg_2Si and Si was studied. The Si is just as effective as the Al_2Cu but less than the Mg_2Si, which, however, should not exceed 1.5% for the best mechanical properties. JZB (10b)

Effect of Cold-working and Heat-treatment on the Electric and Magnetic Properties of Pure Nickel (Einfluss von Kaltbearbeitung und Wärmebehandlung auf die elektrischen und magnetischen Eigenschaften von reinem Nickel) H. BITTEL. *Ann. Physik*, Ser. 5, Vol. 32, Aug. 1938, pp. 608-624. Original research. Wires of carbonyl Ni showed an increase in electrical resistance under elastic twisting. If the wire is twisted in a magnetic field the increase is very small; Ni thus behaves exactly like other non-ferrous metals in this respect. Plastic torsion does not cause magnetic anisotropy, and the resistance is changed but little. The wires "recover" from the effects of cold-working at the same annealing temperature; the recovery temperature decreases with increasing degree of deformation. The change in electric resistance is explained as due to certain magnetic phenomena. 16 references. See also *Metals and Alloys*, Vol. 9, July 1938, p. MA 444 L/9. Ha (10b)

A Further Report on Physical Properties and Clinical Value of Platinum-centered Gold Foil as Compared to Pure Gold Filling Materials. R. W. RULE. *J. Am. Dental. Assn.*, Vol. 24, Apr. 1937, pp. 583-603. Original research. Specimens, 10 x 1.5 x 1.5 mm., were prepared in steel dies using "condensers" of different sizes (0.36 and 1 mm.^{2}) and different applied pressures. These specimens were machined in the gage length for the tension tests. Of the 43 specimens prepared, 23 were pure Au and 20 Pt-centered Au foil with Pt ranging from 10 to 40%. Brinell hardness, density, tensile strength and elongation were determined. The average hardness of the pure Au specimens was 54 Brinell, with the range being 38 to 73. The 10 and 15% Pt alloy specimens showed one reading of 62 and 10 ranging from 70 to 78. The 9 specimens of 30 and 40% Pt ranged 88 to 110 Brinell. The average of the high-Pt specimens was 42 points above the pure Au. The densities of the pure golds ranged from 18.0 to 19.5 with an average of 19.1, while the average for the 10 and 15% Pt alloys was 19.5 and for the 30 and 40% Pt, 19.8. The tensile strength was greatly influenced by the size of the condenser (packing pressure), the averages being 38,500 and 28,800 lbs./in.^{2} for the small and large, respectively, for pure Au. For specimens made with the small condenser, the average tensile strengths were 38,500, 47,500 and 50,000 lbs./in.^{2} for pure Au, 10-15% Pt and 30-40% Pt, respectively. The elongations averaged 12.8, 5.5 and 3.9% for the pure Au, low-Pt and high-Pt specimens, respectively. Crystal Au condensed less readily and gave lower values than Au foil, while electrolytic Au gave about equal values. One crystal Au was condensed with a fluid, as recommended by the manufacturer, but showed practically no cohesion. The Pt-centered foil can be used to develop higher hardness, better wear resistance and higher strength than can be obtained with pure Au foil. Some care in annealing the Pt-centered foil is recommended to avoid "burning off" the Au and thus decreasing cohesion. **Gold Foil and Platinum-centered Gold Foil; Methods of Condensation.** *Ibid.*, Nov. 1937, pp. 1783-1791. Comparisons were made with pure Au foil and 16 and 30% Pt-centered foils, using pellets of ¼ and ½ grain sizes and 5 methods of condensing. Specimens were prepared in steel dies and in "ivorine." The smaller pellets produced specimens of higher hardness and of greater strength. The thinner golds were easier to condense and generally gave specimens of higher hardness and greater strength. Specimens prepared in "ivorine" showed lower hardness and lower strengths than specimens prepared in steel dies. The maximum hardness for pure Au was 65 Brinell, and for 30% Pt 98. The maximum tensile strengths were 45,000 and 61,000 lbs./in.^{2} for pure Au and for 30% Pt, respectively. Using heavier foil for the Pt-centered material seemed to eliminate "burning off" of the Au in annealing. OEH (10b)

Properties and Microscopic Structure of Gold and Gold-platinum Foils. JOHN S. SHELL. *J. Am. Dental Assoc.*, Vol. 24, Nov. 1937, pp. 596-603. Original research. Compare with preceding abstract. Specimens (10 x 1.5 x 1.5 mm.) were prepared in steel dies and hardness, tensile strength and microstructures determined. The specimens were turned to 1.25 mm. diameter and 7 mm. gage for tension tests. The average hardness of pure Au was 54 Brinell, which falls in the range (40-75) for soft casting golds. The 10-15% Pt foils averaged 78 Brinell, which is within the range (70-100) for medium hard casting golds. The average for the 30-40% Pt specimens was 96, which is within the range (90-140) for hard casting golds. The average tensile strengths were 36,000, 45,000 and 40,000 lbs./in.^{2} for pure Au, 10 and 15% Pt, and 30 and 40% Pt, respectively. One specimen, 45% Pt, showed a tensile strength of 59,000 lbs./in.^{2} The density ranged from 98.2 to 99.9% of the theoretical or calculated density. The highest density was for a 10% Pt. specimen. The microstructure showed some slight lack of complete homogeneity in all specimens and the Pt-alloys showed some areas of Pt color. "Crystal" Au condensed to as homogeneous structures as the other materials but showed lack of cohesion, and it was impossible to prepare specimens for tension tests. The value of higher strengths in the Pt-alloy foils is evident for some applications. OEH (10b)

Contact Problems in the Use of Pure Magnesium as Bus Bar Material (Kontaktfragen bei der Verwendung von Reinmagnesium als Stromschienenwerkstoff) W. BULIAN. *Elektrotech. Z.*, Vol. 59, Aug. 18, 1938, pp. 879-881. Descriptive. The low specific gravity (1.74) of Mg permits lighter structures than for Cu or even Al bus bar systems, and the greater strength of Mg is another advantage over Al. Experiments have shown that bolted connections give better and longer durable contacts than Al joints, a contact pressure of 7,000 lbs./in.^{2} being sufficient. Ha (10b)

Tin-coated Light Metal Pistons (Leichtmetall-Kolben mit verzinnter Lauffläche) W. MUNDORFF. *Deut. Motor Z.*, Vol. 15, Feb. 1, 1938, p. 4. Original. 3 pistons of different surface finish were broken in at —110° C. by 20 starts of 1 min. duration. The untreated piston exhibits many surface defects. One piston, treated by the Eloxal method, showed slight wear. The Sn-coated piston was free from any defects of the surface. EF (10b)

The Mechanical Properties of Aluminum-magnesium Alloys. BRONIEWSKI, BERNACIAK & BLAZEWSKI. *Aluminum & Non-Ferrous Rev.*, Vol. 3, Oct. 1938, pp. 365-368. Original research. Primary alloys of Al (impurities of 0.4%) with Mg (impurities of about 0.3%) were investigated. An electric resistance furnace was used for fusion. Heat treatment used was: Annealed for 3 hrs. at 450° C., furnace-cooled to 100° C. (12 days), air cooled; quenched from 450° C. (after 5 hrs. at temp.) in water of 20° C.; tempered at 200° C. (3 hrs.), then quenched in water. For Al-base alloys, the effect of heat treatment becomes evident with 5% Mg. Quenching gives maximum elongation and contraction; tempering results in maximum strength and elastic limit. At 8% Mg, the deformation reaches a minimum; from there on it increases with higher Mg content. For Mg-base alloys, tensile strength and elastic limit increase with Al content. The hardness curve of Al-base alloys is similar to the strength curve. The impact value drops rapidly with increasing Mg content for the annealed alloys; this drop is less marked for hardened alloys, as the impact value stays above 4 kg.-m./cm.^{2} up to 9% Mg. For Mg-base alloys, the hardness increases with Al. Impact is low with 1 kg.-m/cm.^{2} at 5% Al. Outstanding compositions of the 2 types are: (1) 91% Al, 9% Mg, water quenched; (2) 94% Mg, 6% Al. RPS (10b)

The Influence of Beryllium on Brass Alloys (Ueber den Einfluss von Beryllium auf Messing-Legierungen) W. HOCK, FINOW &. P. RÖNTGEN. *Metallwirtschaft*, Vol. 17, **Part I. Microstructure,** Sept. 23, 1938, pp. 997-1003; **Part II. Age Hardening and Mechanical Properties,** Sept. 30, 1938, pp. 1022-1028. Original research. Study of the effects of additions of 0.1, 0.2, 0.5 and 1% Be on the microstructure and age hardening properties of several brasses containing 72, 67, 64, 60 or 57% Cu. The addition of Be causes grain refinement, and the $\alpha/\alpha + \beta$ and $\alpha + \beta/\beta$ phase boundaries of the Cu-Zn system are shifted toward higher Cu concentrations. In this respect Be is more powerful than Al. The tensile strength and hardness of the various brasses is increased by the addition of Be, the additions of which are more effective in alloys with an α matrix than in those with a β matrix. The precipitation hardening effect is greatest in an alloy with 72% Cu. Corrosion tests in 3% NH_3, 3% H_2SO_4, 3% HCl and 3% NaCl showed no detrimental effect of Be on the corrosion resistance of these alloys, in several cases apparently increasing the corrosion resistance. GA (10b)

Copper Alloys in Engineering. Their Adaption to Modern Requirements. H. J. MILLER. *Metal Ind., London,* Vol. 53, Nov. 11, 1938, pp. 461-464; Nov. 18, 1938, pp. 493-496; Nov. 25, 1938, pp. 521-524. Review. Modern Cu alloys are classed as: Materials for service at elevated temperatures, high strength constructional alloys, alloys for bearing service and free machining materials. High purity Cu may be completely annealed at less than 200° C.; therefore, special alloys are employed when high temperatures are involved. Tough pitch Cu, because of its cuprous oxide content, deteriorates by "gassing" when heated in reducing atmospheres. For this reason, considerable use is made of P-deoxidized Cu, which contains about 0.015-0.05 P. The P has little influence on the mechanical properties, but the electrical conductivity is reduced to about 70%. Several other elements have been used as deoxidizers; where high electrical conductivity is required, O-free Cu made by other methods is available. O-free and deoxidized Cu are not only easy to weld but are often superior in service. Cu alloys containing Al, Mg or Be, which form protective films, are used where resistance to oxidation at elevated temperatures is necessary. Alloys of 5-11% Al are outstandingly useful in this respect. Resistance to oxidation may be enhanced by selective oxidation. Absolute resistance to oxidation is seldom necessary and it is often satisfactory to use only slightly modified varieties of Cu. Elevated temperature service requiring retention of mechanical properties may be divided into 2 classes: That in which work hardness must be retained, and that in which the metal is used in the annealed state. Retention of cold work at slightly elevated temperatures is found in Cu-Ag; Ag or Cd raises the annealing temperature without excessively depressing conductivity. 1% Cd-Cu can be used at temperatures up to 200° C. With precipitation-hardening alloys used for welding electrodes, continued exposure to temperatures almost up to the precipitation range will not result in softening, even in very long periods of time. The maximum service temperature of Cu-Cr alloys is placed at 350° C. Cu-Ni-Si alloys (97.5 Cu, 2 Ni, 0.5% Si), which precipitate Ni_2Si, possess good hardening characteristics, but may be too brittle for service requirements. To overcome this, modified alloys, such as 98.75 Cu, 0.75 Ni and 0.5% Si, have been developed. Cu-Co-Be and Cu-Ni-Al alloys are also serviceable at elevated temperatures. An important feature of the Cu-Co-Be alloy is that it has an electrical conductivity of over 50% and can be used at 400° C. For turbine blading, P-bronze is still used to some extent for the low-pressure stage, but in the high-pressure stage Cu-base alloys have been displaced by Monel. The high temperature properties of Cu-Ni improve as the Ni is increased to about 70%. Cu-Mn (5 Mn) alloy is favored for locomotive stayrods. Cu-Al alloys are good up to 400° C. Correlation of creep performance with certain other properties has been attempted and it is apparent that materials with high recrystallization temperatures are desirable. Temper hardening alloys with a high optimum heat treatment temperature, such as Cu-Cr, Cu-Co-Be, Cu-Bi-Al and Cu-Ni-Si series, all of which are heat treated in the range 450°-550° C., are better than those alloys with a low heat treatment temperature, as typified by the Cu-Ni-Sn and Cu-Be series, which harden at about 300° C. Cu alloys now available for room-temperature service are numerous in comparison with those of a few years ago. Maximum electrical conductivity coupled with strength is found in 0.5-1% Cd alloys. Wire of this alloy has 50% greater strength than hard drawn Cu with an electrical conductivity of about 83-95%. When conductivity is unimportant, increased tensile properties may be obtained by additions of Sn, Si and Al. Cu-Fe-P alloys (2 Fe, 0.5% P) may be heat treated to give high conductivity values (90%). Cu-Cr alloys are of most importance in the cast condition. Wrought Cu-Cr alloys lack the strength of Cu-Cd. Co and Be additions give tensile strengths up to 50 tons/in.^{2} with an electrical conductivity of about 50%. In the development of new casting alloys, relatively little progress has been made in recent years. Ni additions to gunmetal give better mechanical properties. The favored alloy is 88 Cu, 5 Sn, 5 Ni and 2% Zn. Cu-Be of 2.25-2.5 Be responds to heat treatment and develops high tensile strength. In tonnage, the largest single use of Be-Cu is for minimum-sparking tools. Until recently, fabrication of Cu-Sn alloys was confined to the α range, with 9% as the limiting Sn content for cold work. With the new low-gas technique in casting, it is possible to fabricate alloys of 14% Sn. Low temperature heat treatments not only reduce the tendency to season-crack, but improve the proportional limit and proof stress of cold-worked materials. The Cu alloys used for corrosive services include brasses, Si-bronze, Al-bronze and alloys with Ni. Cu alloys for bearings have been conventionally based on cast Cu-Sn and Cu-Sn-P alloys. Recent developments include wrought, molded and Cu-Pb bearings. Wrought bronzes are usually 8-10% Sn. Additions of either Cr or V with Fe results in a duplex system of α-solid and alloy-rich intermetallic compound. Porous bearings are made by feeding Cu and Sn powder with graphite into molds in self-ejecting presses; the formed products are afterwards sintered in reducing atmospheres. Typical Pb or "plastic" bearing bronzes are 78/7/15 or 70/5/25 Cu/Sn/Pb. Modern Cu-Pb bearings for high duty service were evolved from these. Production technique varies, but invariably the Cu-Pb is applied as a very thin layer on a steel shell. Free machining materials are also discussed. 37 references. RWB (10b)

1

New Nickel Alloy. *Heat Treating Forging,* Vol. 24, Oct. 1938, p. 507. Describes properties of "Z-Nickel," which contains 98% Ni and can be heat treated to give high strength values while retaining corrosion resistance of Ni. It has a density of 8.75; specific gravity of 0.316 lb./in.^{2}; electrical resistivity of 84-96 ohms/mil-ft. at 20° C., temperature coefficient being 0.0036/1° C.; tensile modulus of elasticity of 30,000,000; and torsional modulus of elasticity of 11,000,000. Strength is 2.5-4 times that of ordinary structural C steel. It has been produced with tensile strength of 250,000 lbs./in.^{2} and hardness of 46 Rockwell C. In the unhardened or annealed state, it fabricates almost as easily as pure Ni. It can be heat treated after fabrication with little distortion, since heat treating is done at 890°-930° F. for 6-16 hrs. Hardening in an H_2 atmosphere, which need not be dried, prevents slight discoloration. Quenching from 2000° F. is required to render the alloy susceptible to heat treatment. It is produced commercially as hot-rolled or cold-drawn rods, wire and cold-rolled strip, furnished unhardened or heat treated. Unhardened cold-rolled strip is produced in soft, half-hard, or full-hard tempers with minimum tensile strengths of 90,000 lbs./in.^{2}, 130,000 lbs./in.^{2} and 155,000 lbs./in.^{2}, respectively. Heat treatment increases these by 30,000-70,000 lbs./in.^{2} The range of mechanical properties is tabulated. MS (10b)

The Development of High-strength Electrical Conductors and Messenger Cables. C. H. DAVIS & I. T. HOOK (Am. Brass Co.) *Wire & Wire Prod.,* Vol. 13, Nov. 1938, pp. 665-670, 692. Exhaustive survey and complete description of experiments and experiences leading to the present perfection of messenger cables that have a tensile strength of 73,000 lbs./in.^{2} with 2.75% elongation in 10 in. for wire 0.365 in. diameter. Cu alone does not develop more than 66,000 lbs./in.^{2}; Cu alloyed with Sn only is unsatisfactory for messenger cable strand, as difficulties in hot-rolling and cold-drawing occur with 3% Sn. Al-Cu and Si-Cu alloys give better strength but a greatly reduced electrical conductivity. Sn bronze, deoxidized and hardened with 3% Si, is difficult to hot-roll and cold-draw, and is unsuitable for messenger strands. Sn bronze deoxidized with either Al or 2% Si gives satisfactory strength, but low conductivity. Increasing amounts of Al added to Cu increase suitability. 5% Al and 95% Cu is an exceptionally good hot forging bronze. Tables showing mechanical properties of different bronzes are given. The properties of "Calsun" bronze (Cu-Al-Sn, U. S. Patent 1,630,999), which is corrosion-resisting and has 17% conductivity, are discussed. Ha (10b)

Studies on Gallium, Indium and Thallium (Studien über das Gallium, Indium und Thallium) E. EINECKE. *Z. anorg. allgem. Chem.,* Vol. 238, July 1, 1938, pp. 113-174. Experimental. Many of the properties of Ga, In and Tl were studied, some for the first time. The hardness, ductility and tensile strength of Ga single crystals were determined. In contrast to the exceptionally plastic metals In and Tl, Ga is brittle and unyielding almost up to its melting point. Unlike In and Th, Ga could be welded by methods excluding O. The laws of solidification speed observed in non-metals should, according to the observations made on Ga, be valid for metals also. The constancy of linear and cubic crystallization per unit time at a definite temperature was established and the dependence of the freezing on the cross-section and super-cooling was studied. Ga is mechanically dispersable into only coarse emulsions, but its colloid synthesis is possible by electrochemical means that are described. The anodic behavior of Ga in alkali, acid and neutral electrolytes was studied, together with its polarizability. The electrolytic valve action of Ga was studied in both solid and liquid states. The potentials and degree of rectification (in part comparable to those of Al) were determined. All properties of Ga studied were compared in detail with the corresponding properties of its neighboring metals in the periodic system especially In and Tl. HFK (10b)

The Latent Heat of Fusion of Aluminium. J. H. AWBERY. *Phil. Mag.,* Vol. 26, Nov. 1938, Suppl., pp. 776-784. Research. A review of published values shows 2 different groups, one with a mean value of about 92 cal./g., the other 77 cal./g. A new electrical melting method was used and 92.4 ± 0.5 cal./g. was established as the most probable value. The low values in literature are attributed to impurities in the samples or inaccuracies of methods used for the determination. 8 references. Ha (10b)

The Effect of Small Lead Additions on Silumin (Ueber den Einfluss geringer Bleizusätze auf Silumin) H. BAUER & H. WINTERHAGER. *Aluminium,* Vol. 20, Oct. 1938, pp. 700-704. Original research. Small additions of Pb (in the form of lead chloride) to eutectic Al-Si casting alloys were investigated. No improvement on the mechanical strength could be observed. In alloys with 0.5% Mg and Pb from 0.07 to 0.5% the Pb comes to the surface after annealing at 525° C.; this does not occur in alloys with 1% Mg and 0.1% Pb. Ha (10b)

Influence of Elements on the Properties of Lead. Part VII. The Influence of Composition on the Creep Rate of Industrial Lead. J. NEILL GREENWOOD & HOWARD K. WORNER. *Proc. Australasian Inst. Mining Met.* No. 104, Dec. 31, 1936, pp. 385-422. Original research. For Part VI, see *Metals and Alloys,* Vol. 8, Oct. 1937, p. MA 629 L/1. Ag in the cast alloy occurs partly as free particles and partly as solid solution. By suitable treatment, up to 0.1% Ag can be taken into solid solution. This amount of Ag increases hardness and resistance to creep. Ag decreases grain size after rolling. The creep rate (50-100 days) of alloys containing 0.01-0.05% Ag is of the order 3 x 10^{-5} in./in./day under a stress of 350 lbs./sq. in. in the basically annealed condition. Ag-Pb is not appreciably different from ordinary Pb in retaining cold work hardness at room temperature, but this may not be true if Ag is in solid solution. Sb in amounts used is in solid solution. It has little influence on hardness or rate of creep at 350 lbs./in.^{2} The creep rate (50-100 days) under this stress for alloys containing up to 0.1% Sb is of the order of 9 x 10^{-6} in./in./day in the basically annealed condition, about 3 times the rate for Ag alloys. Under 500 lbs./in.^{2} stress, creep rates of these alloys are greater than for Port Pirie Pb; Russell reported a decrease in rate with 0.05% Sb in electrolytic Pb, indicating the marked influence of traces of elements. An alloy containing 0.01% Sb was exceedingly sensitive to grain growth on annealing. With 0.1% Sb, the alloys gave a more regular and greater elongation than Port Pirie Pb and finally broke in an intercrystalline manner. Bi shows appreciable solid solubility in Pb. It has little influence on hardness. A slight increase in Bi caused a marked initial increase in rate of creep, but as Bi was further increased, this effect became less and less. In the basically annealed condition, this anomaly disappeared and Bi had little influence. Creep rate (50-100 days) of Pb alloys containing up to 0.1% Bi under 350 lbs./in.^{2} stress is of the order of 7x 10^{-5} in./in./day. Bi has little effect on grain size after rolling, but the alloy containing 0.005% Bi was very sensitive to grain growth on annealing. Zn shows slight solid solubility in Pb, about 0.1%, this solution forming a eutectic with any excess Zn over this amount. Zn decreases creep rate slightly, but the effect is neither so marked nor so regular as that of Ag. **Part VIII. The Influence of Copper.** J. NEILL GREENWOOD & C. W. ORR. *Ibid.,* No. 109, Mar. 31, 1938, pp. 1-24. Cu is only slightly soluble in Pb, and even 0.007% can be detected microscopically in cast and rolled alloys. Up to 0.06% Cu is dispersed in fine particles as a eutectic; above this, Cu crystals appear with a tendency to mechanical segregation. Cu does not greatly affect the hardness of Pb, either annealed or rolled. Up to 0.01% Cu increases creep rate; further additions up to 0.06% cause a rapid fall in creep rate, and after this there is substantially no further effect. Cu increases the stability of the crystal lattice of Pb, enabling the latter to withstand greater deformation without recrystallization. Vibration superposed on direct stress appreciably increases creep rate. Pb containing 0.07% Cu has a creep rate under 350 lbs./in.^{2} stress and with vibration about 0.1 that of Point Pirie Pb. Pb containing 0.06% or more of Cu, even with vibration under 350 lbs./in.^{2} stress, stretches less than 1% in the first year and develops a creep rate of less than 0.5%/annum; Point Pirie Pb gives this result with stress less than 200 lbs./in.^{2}. AHE (10b)

10c. Effect of Temperature

H. C. CROSS, SECTION EDITOR

The abstracts in this section are prepared in cooperation of the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necesharily subscribed to the statements of either the author or the abstractor.

Investigation of the Suitability of High Temperature Materials for Combustion Engines (Untersuchung über die Eignung Warmfester Werkstoffe für Verbrennungskraftmaschinen) F. BOLLENRATH, H. CORNELIUS & W. BUNGARDT. *Metallwirtschaft,* Vol. 17, July 15, 1938, pp. 755-757. Research. Investigation was made of 24 alloys consisting of austenitic steels and low-Fe heat resistant alloys with regard to their use for an exhaust turbine operating at high temp. The stress necessary to produce a 1% elongation in 300 hrs. at 600° C. was taken as a criterion for the suitability of these materials for turbine blades. From data on the 24 materials tested it was determined that Ti additions in small amounts (1-3%) increase the high temp. creep strength most. Of the various elements studied, Ta and Cb are next in order as regards increase of high temp. strength of steels to which they are added. [In the austenitic steels, the effect of significant differences in Cr and Ni content have been neglected and the beneficial effects of Ti, and Ta and Cb are not proved.—H.C.C.] GA (10c)

The Creep Strength of Fusion-weld Electrode Materials (Untersuchungen über die Dauerstandfestigkeit von niedergeschweissten Elektrodenwerkstoffen) H. M. SCHNADT. *Arcos Z.,* Vol. 15, Aug. 1938, pp. 1851-1860. Original research. 2 types of electrodes were studied: (1) 0.14 C, 0.51 Mn, 0.05 Si, 0.02 S, 0.02% P; and (2) 0.10 C, 0.92 Mn, 0.03 Si, 0.02 S, 0.02% P. Temperatures of 450° and 500° C. were employed with the following results:

Electrode No.	Temp., °C.	Stress (lbs./in.^{2}) to produce creep rates between 25th and 35th hrs. of 1.5×10^{-3}%/hr.	1.0×10^{-3}%/hr.	0.5×10^{-3}%/hr.
1	450	19,500	18,500	16,300
2	450	21,300	20,000	17,100
2	500	13,100	12,100	9,400

It was also shown that (a) at 450° C. the creep strength of each electrode material is at least equal to that of rolled or forged steels of similar composition and heat treatment; (b) between 450° and 500° C. the drop in creep strength of electrode (2) was very similar to that of simultaneously tested comparison steels; and (c) at 500° C. the creep strength of electrode (2) is at least equal to that of corresponding rolled steels. [It should be remembered that what the author calls creep rates are more of the nature of proportional limit tests and bear no sure relation to long time creep.—H. W. G.] GN (10c)

Determination of the Creep Limit by Various Methods (Bestimmung der Dauerstandfestigkeit nach verschiedenen Verfahren) A. KRISCH. *Arch. Eisenhüttenw.,* Vol. 12, Oct. 1938, pp. 199-206. Original research. The creep limit at 500° C. of a 0.12% C, 0.33% Mo and 0.20% Cu steel and of a 0.15% C, 0.80% Cr, 0.53% Mo and 0.13% Cu steel was determined by 12 different methods, including those used in Germany, by the National Physical Laboratory and others in England, and by laboratories in the United States. In general, the different accelerated tests and those tests in which the creep limits were for total extensions as large as 1% in 10,000 hrs., gave fairly consistent values, the deviations being within ± 2,800 lbs./in.^{2} Tests such as the determination of the creep limit at a stress giving a creep rate of 5 x 10^{-4}% per hr. during the 25th to 35th hrs. (German method); the determination of the load giving a total extension of 0.1% in 10,000 hrs. (American method); and the determination of the load giving a creep rate in the 24th to 72nd hr. of less than 1 x 10^{-4}% per hr. (Hatfield's "Time Yield" method) gave lower values. Impact tests and microscopic examinations after 1,000 hrs. loading showed no changes in the steels. SE (10c)

The High Temperature Properties of Magnesium Alloys (Elektron) under Static Tensile Stressing (Die Warmfestigkeits-Eigenschaften der Elektron-Legierungen bei statischer Zugbeanspruchung) H. VOSSKÜHLER. *Metallwirtschaft,* Vol. 17, Sept. 2, 1938, pp. 935-941. Original research. Excellent compilation of the high temperature properties of standard Elektron (Mg-base) alloys. Tensile strength, yield strength, proportional limit, elongation, reduction in area and hardness are reported for each alloy for temperature ranging from 20° to 300° C. The alloys were studied in 3 conditions: Sand cast, permanent mold cast and extruded. Various heat treatments that affect the microstructure have no influence on the high temperature properties above 200° C. No differences in properties was discerned for permanent mold and sand castings above 150° C. Extruded stock is no stronger than cast material at temperatures over 200°-250° C., though the high temperature ductility is considerably greater in the extruded alloy. The addition of Al to Mg enhances the high temperature properties of the alloy, while the addition of Zn to binary Mg-Al alloys within the amounts present in commercial alloys exerts no influence on the high temperature properties. GA (10c)

Impact Strength of Metallic Materials at Low Temperatures, down to Temperature of Liquid Hydrogen (Die Kerbschlagzähigkeit metallischer Werkstoffe bei tiefen Temperaturen bis zu Temperatur des flüssigen Wasserstoffes) G. HAUPT & A. KRISCH. *Naturwiss.,* Vol. 26, June 17, 1938, pp. 390-393. Research. Results are given in the Table:

Material	Charpy Impact in m-kg./cm.^{2} + 20° C.	− 253° C.
99% Ni	32	22
Steel with 0.11% C, 17.7% Mn, 9.9% Cr, 1% Mo	33	22
Steel with 0.13% C, 15.5% Mn, 14.2% Cr, 1.1% Ni, 0.1% Mo	29	22
Steel with 0.11% C, 17.7% Cr, 8.5% Ni, 1% W, 0.2% Mo, 0.2% Ti, 0.2% Cu	24	20
Steel with 0.10% C, 18.0% Cr, 8.1% Ni, 0.5% Ti, 0.3% Mo	26.5	14.5
Steel with 0.04% C, 36.0% Ni	21.5	13
99.96% Cu	10	13
Steel with 0.24% C, 25.0% Cr, 24.4% Ni	15	10.5
Steel with 0.09% C, 9.4% Mn, 16.9% Cr	20.5	8
Steel with 0.08% C, 3.2% Si, 17.2% Mn, 7.7% Cr, 0.1% Ni	16.5	4
Commercial Pb	2	4
Steel with 0.41% C, 1.7% Cr, 0.4% Mo, 0.25% V	15	2

11·CORROSION AND WEAR

Chemical and Atmospheric Corrosion and Oxidation. Abrasion, Cavitation and Erosion. See also Sections 7 and 10.

V. V. KENDALL, SECTION EDITOR

The Electrochemistry of Corrosion. R. H. BROWN & R. B. MEARS (Aluminum Res. Labs.) *Trans. Electrochem. Soc.*, Vol. 74, 1938, Preprint No. 2, 19 pp. Original research. The corrosion of Al in chloride solutions is electrochemical in nature. The corrosion of oxide-coated Al occurs in the form of small isolated pits. The total current flowing between pitted and uncorroded areas is directly proportional to the cathodic area and nearly independent of the anodic area. An increase in the number of pits (anodic areas) will not increase the corroding current, but will reduce the current density on these anodic areas and, hence, also the intensity of attack. The measurement of the potential of a corroding specimen does not give information concerning the intensity of corrosion, as the potential depends on the number of breakdowns and on the type of solution. In a chloride solution the first breakdown of the oxide film is indicated by a change of potential, but further breakdowns cause little change in the potential. The potential of a specimen corroding in K_2SO_4 solution gradually becomes more negative as the breakdowns increase. The measurement of the current flowing in a corrosion cell, by the method of shorting the cell through an ammeter, sometimes gives less than the true short circuit value, because of the resistance of the ammeter. This objection is obviated by a "zero resistance" method which uses an external source of e.m.f. to bring the anode and cathode to the same potential against the solution. The current flowing at this point is the corroding current. **A Theory of Cathodic Protection.** R. B. MEARS & R. H. BROWN. *Ibid.*, Preprint No. 3, 9 pp. Original research. According to the electrochemical theory of corrosion, a potential difference is set up between adjacent areas of a metal because of heterogeneities of the surface or of the medium. The system resembles a short circuited cell, in which the negative electrode corresponds to the corroding or anodic areas, and the positive electrode corresponds to the cathodic or uncorroded areas of the metal. The flow of current causes attack only of the anodic areas. It polarizes the cathodic areas until the potential of these areas against the solution is the same as the potential of the anodic areas against the solution. The freely corroding current is determined by the current density required to polarize the cathodic areas until they have the same potential as the anodic areas. The current density (applied by an external e.m.f.) required to prevent attack of a metal must be high enough to polarize the cathodic areas until they gave the same potential (against the solution) as the static potential of the anodic areas. In experiments with Zn and Cu electrodes, the Cu electrode was cathodically polarized with the aid of an auxiliary Pt electrode until its potential was the same as that of the Zn electrode. Under these conditions no corroding current flowed between the Zn and Cu. AB (11)

Examination of a Sheet of Aluminum Exposed for 40 Years in an Urban Atmosphere. CARLO PANSERI. *J. Inst. Metals*, Vol. 63, 1938, Advance Copy 802, 6 pp. The Al examined was a sheet originally 1.3 mm. thick installed on a cupola of a church in Rome in 1897. The metal was of low quality, containing 1% Si and 0.6% Fe, probably of Swiss origin, and shows the characteristic microstructure for such material in the half-hard condition. Some parts of the sheet were practically unaffected by the exposure, and the corroded zone was no more than 0.05-0.15 mm. deep. Tensile properties were comparable with unexposed material of same analysis. Lack of severe corrosion was attributed to design and ventilation of cupola, which have prevented accumulation of water. JLG (11)

Thermomagnetic Study of Rust (Étude Thermomagnétique des Rouilles) ANDRÉ MICHEL & MARGUERITE GILLISOT. *Métaux et Corrosion*, Vol. 13, Aug. 1938, pp. 144-146. Original research. Thermomagnetic methods permit following the process of crystallization (ferrites, oxides), in detail. In the present study, a recording thermomagnetic apparatus, Chaudron-Forester type, was used. The Fe rust is considered to consist of a mixture of oxides (magnetite, cubic sesquioxide) and hydrates (monohydrate Fe_2O_3 . H_2O occurring as goethite and lepidocrocite). Thermomagnetic analysis distinguishes between goethite and lepidocrocite, since on dehydration lepidocrocite changes to strongly ferro-magnetic cubic Fe_2O_3, whereas goethite changes to slightly ferro-magnetic rhombohedric Fe_2O_3. An Fe rod covered with tar and subjected to seawater corrosion, when examined thermomagnetically, exhibited tar anomalies; (1) Dehydration of the rust, and (2) a reduction by the organic impurities. The sesquioxide was reduced to Fe_3O_4, thus increasing the magnetization. Thermomagnetic analysis is a rapid method for detecting the presence of lepidocrocite in rust. X-ray examinations revealed that the cubic sesquioxide consists of extremely fine grains. 7 references. GTM (11)

Cracking of Steel in Ammonium Nitrate Solutions. W. ANDREWS. *Metallurgist* (*Suppl. Engineer*) Aug. 1938, p. 160. Letter to the editor. Reports results of examining, metallurgically, samples of mild steel equipment that had failed while handling solutions of nitrates. Failures were confined to mild steel equipment in which calcium and ammonium nitrates were handled; equipment handling sodium nitrate appeared to be immune. Microscopic examination suggested that the intercrystalline attack was connected with chemical attack on the iron carbide in the steel, when located in or contiguous to the crystal boundaries. It was also noted that only those liquors containing ammonium nitrate, *i.e.* calcium nitrate containing some ammonium nitrate and ammonium nitrate itself, caused disintegration to occur and if the solution were free of ammonium nitrate, *e.g.* the sodium nitrate solution, no trouble was experienced, even in riveted joints. Experiments on pure iron carbide indicated that ammonium nitrate was the bad actor, according to the equation: $15\ H_2O + 3\ NH_4NO_3 + 4\ Fe_3C = 12\ Fe(OH)_2 + 6\ NH_3 + 4\ C$. VVK (11)

The Low Temperature Oxidation of Iron. H. R. NELSON (Battelle Mem. Inst.) *J. Phys. Chem.*, Vol. 6, Oct. 1938, pp. 606-611. Original research. Electron diffraction study of the oxide films formed on an abraded (Armco) Fe sample by heating in air at 80°-260° C. showed no structural effects due to a "critical temperature" in the neighborhood of 200° C. α-Fe_2O_3 was found on samples oxidized above 130° C. provided the oxidation time exceeded a minimum value, which depends on temperature. Thus, 1 hr. at 180° C., 4 hrs. at 165° C., 13 hrs. at 150° C. or 1000 hrs. at 130° C. are just sufficient to produce a well-defined diffraction pattern. Lower oxidation temperatures or shorter times tend to strengthen the diffraction pattern due to the primary oxide film (γ-Fe_2O_3 or Fe_3O_4). This is not accompanied by appreciable grain growth, and traces of Fe are present in the pattern after oxidation periods as long as 1700 hrs. at 120° C. or below. It is estimated that the primary oxide film cannot be thicker than about 200 A.U. over some portions of the abraded surface. Above 193° C., a new α-Fe_2O_3 film appears, which is more coarsely crystalline and has a different type of preferred orientation than the first-formed α-Fe_2O_3 film. This secondary film may be formed by the outward diffusion of Fe through the oxide layer. The axis of preferred orientation of the α-Fe_2O_3 is always symmetrical about the normal to the surface. This orientation cannot be ascribed to pseudomorphism of the oxide crystals on the underlying Fe, as is the case with the primary oxide. EF (11)

A Search for an Alloy Resistant to Hydrochloric Acid Corrosion. K. T. VASHENKO. *Zhur. Khim. Prom.*, Vol. 15, No. 2, 1938, pp. 39-47. In Russian. Laboratory and commercial operating tests demonstrated that Fe-Si alloys containing Mo resist corrosion by HCl of all concentrations and at all temperatures up to boiling. The most resistant composition was 14-16% Si and 3-4% Mo. The corrosion resistance of alloys within this range is 8-10 times higher than alloys containing the same amount of Si, but no Mo. Hardness as well as acid-resistance increased with rise in Si and Mo contents. Na (11)

E. F. CONE, SECTION EDITOR

Sintered Metals (Sinter-Metalle) H. E. HONISCH. *Chem. Z.*, Vol. 62, Nov. 16, 1938, pp. 829-831. Practical discussion of powder metallurgy. The advantages and applications are illustrated by high-melting metals, such as Mo, W, Ta and Os whose casting is not practical, and carbides used for cutting tools. Sintering is defined as heating of granular material (such as ceramics or metals) close to the melting point so that surface softening and fritting occur. The grains stick together, forming a more or less porous skeleton of an unmelted and chemically unchanged material. Methods of production of metal powders are: (1) Reduction of oxides by means of H_2, CO, or admixed C (soot, graphite); this is applied for W, Mo, Co, Ni, Fe. (2) Deposit of metals from salt solution by means of liquid or solid reducing agents; this is applied for Ti. (3) Precipitation of metal powders from carbonyls. (4) Mechanical disintegration of metals. (5) Spraying by the electric arc. Homogeneity of the powders and uniform grain size are required, and are best obtained by chemical processes. Otherwise, mechanical separation by screening, elutriating or air sifting is necessary. The production of sintered metals starts with the pressing operation. Pressures of 1,000-5,000, sometimes even 10,000 atmospheres (15,000-70,000, 150,000 lbs./in.^{2}, respectively) are used. High pressures produce greater wear on the dies. After compression, pieces possess enough strength to permit them to be handled. The next step is presintering, usually in an electric furnace at 300°-1500° C., depending upon materials used, which gives a product that can be machined. A second sintering gives the final strength, hardness and characteristic properties. When using carbides, additions of binder metals are made, to improve machinability and reduce brittleness. Co or Ni in amounts up to 20% are used. Temperatures are high; C-short circuit or high-frequency furnaces, or sometimes Mo-or W-wound resistance furnaces, are used. The effect of the binder is explained by its cementing action, which results in a mechanical mixture with some alloying at the grain interfaces. The wide application of the sinter process is justified by the hardness obtainable, corrosion resistance and, in many instances, economy. W-wire, widely used as filament in electric bulbs and heating elements, is made by pressing, swaging and stretching under heat (electric current flows through piece), drawing through diamond dies. Surgical instruments can be made from Ta powder. Fe powder is used, *e.g.* for magnetic cores. High-purity Fe powder (*e.g.* carbonyl-Fe) can be sintered in molds without previous pressing. Sheet metal rolled from a sintered block shows excellent deep-drawing properties. By means of additions, Fe alloys with exactly predetermined characteristics (*e.g.* coefficient of expansion) can be produced. The application of oilless bearings is mentioned. [The development in the field of sintered metals is proceeding rapidly and is becoming highly specialized. This article contains only some examples of the process and of its applications.—R. P. S.] RPS (12)

Defects in Steel. JOSEPH A. DUMA (Norfolk Navy Yard) *Heat Treating Forging*, Vol. 24, Mar. 1938, pp. 120-125, 142; Apr. 1938, pp. 174-178, 181; May 1938, pp. 231-236; June 1938, pp. 280-285, 298; July 1938. pp. 333-338, 350; Aug. 1938, pp. 393-396; Sept. 1938, pp. 454-458; Oct. 1938, pp. 504-506. Comprehensive summary of inherent and acquired surface and subsurface defects in steel, omitting those properly the problem of the open-hearth department. Defines each defect and discusses its causes, remedy and detection. Some of the information given is original. Among the subjects treated are forging bursts and cracks; burning and overheating; forge cooling cracks; worm-holes; laps; scaling; flow lines; banding; seams; splits; decarburization; "lip"; mechanical pipe; carbide, blue and secondary brittleness and transformation shortness; quenching and shatter cracks; effect of heat treating processes; grain size; brittleness; methods for discovering defects; zoning; "fire-crock"; "chill"; carburizing defects; nitriding failures; flame hardening; straightening cracks; H_2 embrittlement; pickling defects; welding defects such as undercutting, overlapping, porosity, inclusions, bird-eyes, cracks and decay; testing soundness of welds; brazing; tool, drag and score marks; grinding cracks; stress raisers; surface defects on rolled sheet and strip such as clouds, laminations, blisters, kinks, exfoliation, non-uniform reduction, cracks, ripples, roughening and "Dutch-bending"; intergranular, intercrystalline, Stead's and Sauveur's brittleness; tears from deep drawing; stretcher strains; caustic embrittlement; corrosion fatigue; electrochemical theory of corrosion; protective coatings; intergranular corrosion of stainless steel; corrosion tests; season cracking; heat checks; Zn embrittlement; and failure due to absorption of N_2 when lubrication fails. Includes over 60 references. MS (12)

World's Platinum; Post-war Changes in the Industry. *Chem. Trade J.*, Vol. 103, July 8, 1938, p. 28. From *Economist*, June 25, 1938. Before the World War, Russia supplied 90% of the world's output of Pt, and Colombia the bulk of the remainder. These countries were the most important producers until 1925, though Russian output fell heavily after the Revolution. In 1924, the price was £29 per troy oz., and jewelry trade accounted for more than half of annual estimated demand of 200,000-225,000 oz. After 1924, Transvaal deposits were developed rapidly, so that production in 1930 exceeded that of Colombia. After this, South African supply fell, owing to technical difficulties connected with treatment of ore. Canadian production has increased from less than 17,000 oz. in 1925 to 259,000 oz. in 1937, the latter being considerably more than half the output of these 4 countries. Bulk of Canadian output is a by-product from Ni-Cu ore of Frood mine. Producer, whose direct costs of refining Pt are 7-8s. per troy oz., has encouraged the fall in price (now about £7 per oz.), and has carried out research on possibilities of Pt as an industrial metal, so that a large increase in supplies could be absorbed. As a result, world consumption was about 450,000 oz. in 1937. According to U. S. Bureau of Mines, jewelry trade consumed about 36% in 1936; dentistry, 25%; electrical industry, 14% and chemical industry, 13%. MS (12)

Annual Report of the Metallurgical Division, Fiscal Year 1937-38. R. S. DEAN & OTHERS. *U. S. Bur. Mines Rept. of Investigations* 3419, Oct. 1938, 80 pp. Technical data secured by the Metallurgical Division during 1937-38 in the following investigations are summarized: Measurement of specific heats at low temperatures; measurements of heats of formation and free energies; production of pure sponge Cr at low temperatures; mechanical concentration or unmixing of gases; settling smoke with sound waves; electrolytic Mn; electro-refining of Sb and treatment of Au-Sb ores; alunite extraction; Mg from magnesite; grinding studies; concentration of Fe ores, chromite, a Tenn. Mn ore and an Ill. Pb-Zn-fluorspar ore; flotation of non-sulphide minerals; development of wetting agents for flotation; ore testing projects (14); treatment of Au ores (5); studies of concentrating problems of Mountain City Copper Co., Sunnyside ore, U. S. Smelting, Refining & Mining Co., and Magma Copper Co.; recovery of Pb and Ag from oxidized ores by flotation; microscopy of Tintic ore; improvement in sulphidizing; flotation of oxidized Cu minerals; sintering; Au loss in dredging; recovery of Au in pyrite or base-metal ore; flotation of Ag minerals; flotation of scheelite; analytical investigations; recovery of S from smelter smoke; desulphurization of pig Fe with CaC_2; equilibrium conditions in desulphurizing reactions; coercive-force measurement of C in steel; magnetic behavior of open-hearth slags; metal-slag dispersion. AHE (12)

A Further Study on the Theory of the Change in Electric Resistance in Metals Due to Hydrostatic Pressure. KÔTARÔ HONDA & TOKUTARÔ HIRONE. *Sci. Papers Inst. Phys. Chem. Research, Tokyo*, Vol. 34, Oct. 1938, pp. 1292-1293. In English. Original, theoretical research. The different types of change in electric resistance in metals by the action of extra-high hydrostatic pressure, recently observed by Bridgman (*Metals and Alloys*, Vol. 9, Dec. 1938, p. MA 730L/3) are explained by the authors' previously advanced theory of the nature of free electrons (*Z. Phys.*, Vol. 76, 1932, p. 80). For many metals the calculated results agree satisfactorily with experiment, but for a few metals a further approximation for the calculation of mean free path of electrons is required. The latest calculations satisfactorily explain the new Bridgman data on Cu, Ag, Au, Fe, Pb, Li, Na and Cs. EF (12)

Announcing

SAMPLING AND ANALYSIS OF CARBON AND ALLOY STEELS

Prepared by the Chemists' Committee of The Subsidiaries of the U. S. Steel Corporation

EXACT CHEMICAL SPECIFICATIONS govern the manufacture and purchase of steel products. To insure compliance with these specifications, standardized and minutely accurate analytical procedures are essential. The necessity for standardization of methods becomes evident when it is realized that corrosion and heat resistance and other specific properties, are obtained by the addition to steel of such elements as nickel, chromium, molybdenum, etc., sometimes in almost microscopic percentages. When determinations accurate to the third decimal place are demanded, no tolerance can be allowed for the slightest variation in procedure.

AUTHORITATIVE AND DETAILED PROCEDURES are simply and lucidly presented in this volume. Its aim is to enable any chemist to analyze steels with meticulous accuracy, and it accomplishes this aim by eliminating as far as possible the "human equation." Careful observance of the directions and cautions given will not only reduce the time of determination to a minimum, but will yield absolutely reliable results. This will be of tremendous value to the relatively inexperienced chemist who may have occasion to make check analyses of steel shipments. Since large-scale production of alloy steels is a comparatively recent development, the need for authoritative methods is greater now than ever before, and will be constantly increasing. Everyone interested in testing and analytical work should possess this volume.

SUBSIDIARIES OF THE U. S. STEEL CORPORATION have developed many new methods over a period of years. Their book, 356 pages in length, comprises the most complete and modern body of information on steel analysis that has ever appeared. This corporation has long been prominent in making available to industry everywhere information dealing with sampling and testing of materials used and produced in the iron and steel industry. Eight volumes, totalling 17 editions, published directly by the U. S. Steel Corporation at intervals during the last 30 years, have met an enthusiastic reception the world over, not only within the industry but in scientific libraries and universities. The Reinhold Publishing Corporation has been entrusted with the publication and sale of this latest volume.

THE SCOPE OF THIS BOOK *includes approved procedures for sampling mill products, and for determining all the elements that may occur in steel under any conditions of combination. Methods are given for such infrequently* occurring elements as beryllium and cerium. The first appendix article describes three recent new procedures for determination of sulfur by combustion, most desirable when it is impossible to obtain the sulfur content by older methods. The skeleton table of contents below gives a general summary of the subjects covered.

Because of the extent of the full Table of Contents, only Chapter Headings are given.

Sampling.
Qualitative and Quick Tests for Identifying Various Types of Steel.
Methods of Analysis.
Chemical Separations.
Determination of Manganese.
" " Phosphorus.
" " Sulphur.
" " Silicon.
" " Copper.
" " Nickel.
Determination of Chromium.
Determination of Vanadium.
" " Molybdenum.
" " Titanium.
" " Aluminum.
" " Arsenic.
" " Tin.
" " Cobalt.
" " Tungsten.
" " Uranium.
" " Zirconium.
Determination of Columbium and Tantalum.
Determination of Selenium.
" " Boron.
" " Beryllium.
" " Nitrogen.
" " Antimony, Copper and Molybdenum.
" " Zinc.
" " Cerium.
Appendix I: Determination of Sulphur or Carbon and Sulphur by Combustion in Oxygen.
Appendix II: Discussion of Methods for Oxygen, or Oxygen, Hydrogen and Nitrogen in Steel.
Appendix III: Preparation, pH Ranges, and Color Changes of Various Organic Chemical Indicators.
Appendix IV: Table of Atomic Weights, Atomic Numbers and Other Physical Constants of the Elements.

356 Pages **33 Chapters** **Apparatus Diagrams** **$4.50**

REINHOLD PUBLISHING CORP., 330 W. 42nd Street, New York, U. S. A.

books

National Advisory Committee for Aeronautics, Twenty-fourth Annual Report

Supt. of Documents, Washington, D. C., 1938. Paper, 9 x 11¼ in., 47 pages. Price $.20.

Metallurgical investigations form a very small proportion of those undertaken, compared with those dealing with aerodynamics and the mechanical problems of the power plants. Problems studied that involve metallurgy were, continuation of study of corrosion resistance of alloys of Al and of Mg, effect of subzero temperatures on welded structures (classed as important), evaluation of elastic properties of 18:8, use of stainless steel ignition cable to reduce capacitance, properties of beryllium copper and phosphor bronze for instrument diaphragms, effort to detect deterioration by fatigue in aircraft propellers (no sign of deterioration appears short of an actual crack), determination of crinkling and bending strengths of aircraft tubing, development of a pack method for determining properties of thin sheet under compression, and a method for study of cylinder wear by noting the decrease in size of diamond point impressions.—H. W. GILLETT.

Hardening and Annealing of Steel *(Härten u. Vergüten des Stahles) 4th Edition.*

Hugo Herbers

Verlag Julius Springer, Berlin, 1938. Paper, 6¼ x 9 in., 68 pages. Price 2 RM.

This is No. 7 in the Werkstattbücher series of H. Haake, of which this edition comprises the 25th to 31st thousand. It is a concise, well-written and well-illustrated elementary discussion of heat treatment of carbon and alloy steels, in which the fundamental principles are set forth in such fashion as to lead up logically to their practical application. Although it covers microstructure and property charts in the usual terminology of the metallurgical engineer, it is meant for the education of the "man at the furnace" *(der Mann am Ofen)*, since he can understand what he is trying to accomplish only when he grasps the scientific essentials. Hence it does not hesitate to show space lattice diagrams along with discussions of distortion on quenching.

There are many books dealing with the same field, but few do as complete a job in such small compass. For those who read German it is a very good introduction to the subject. For those who want to learn to read metallurgical German it is a good pamphlet for such study, since it is written in relatively easy German.—H. W. GILLETT.

Sampling and Analysis of Carbon and Alloy Steels

U. S. Steel Corp. Chemists

Reinhold Publishing Corp., New York, 1938. Cloth, 6¼ x 9¼ in., 356 pages. Price $4.50.

Few steel analysts are unfamiliar with the two former booklets of the United States Steel Corp. dealing with methods of sampling and analysis for plain carbon steels and alloy steels used by the chemists of that organization. All analysts familiar with the former booklets will welcome the news that the complete methods as revised to 1937 are now available in book form. The book includes the result of more than two years' cooperative effort of the chief chemists of the various works and research laboratories of the corporation.

Analysis of the usual elements as well as of the less common alloy constituents and impurities are given. The methods are all tested and proved in the corporation's laboratories. The reviewer during the past several years has used many of the methods outlined and has had the opportunity to test others, and highly recommends the new book to all steel analysts. While it is not a textbook, teachers of analytical chemistry will find it a valuable reference book especially for courses in advanced analysis. Chemists and metallurgists not engaged in analytical work will find in the section, "Methods Available," under the determination of each element discussed, some sound chemistry that they may have forgotten. An evening's reading of these sections is recommended.—JOHN D. SULLIVAN.

Chemical Analysis Methods (Umpire) for Aluminum and its Alloys

(Chemische Analysen-Methoden. Schieds Analysen)

P. Urech

Aluminium-Zentrale G.m.b.H., Berlin, 1938. Cardboard, 6 x 8½ in., 68 pages. Price 5 RM.

This book is a German translation of the original French edition edited by the Bureau International des Application de l'Aluminium, Paris. The contents are divided into the following parts: The sampling and preparation of samples for chemical analysis; the preparation and standardization of solutions for volumetric analysis; methods for analyzing aluminum and aluminum alloys, respectively; and schematic methods of analysis.

In general, the methods are well organized. Each method is introduced by a summary and a list of the reagents required. Then follow details of the method, and lastly notes on the method. Methods for only the common impurities and alloying elements for aluminum are included; thus procedures are not given for V, Na, Ag, Ga, Co, Be, Sb, which appear occasionally as impurities or alloying elements.

The method described for zinc is unique and interesting, as the precipitated $ZnHg(CNS)_4$ is determined by titration with KIO_3 solution. It is rather irritating to find the reaction poorly written and improperly balanced.

The Volhard method for manganese is presented as an umpire method. The reviewer feels that the gravimetric precipitation of manganese as manganese ammonium phosphate is inherently more accurate and should be preferred. In any case, ordinary aluminum alloys do not require separation of the manganese prior to titration by the Volhard method.

In the section on preparation and standardization of solutions, several methods are given for standardization of a single solution. The reviewer feels that a book concerning itself with umpire methods of analysis should also adopt the most accurate method of standardization of a solution and not give a choice of 4 methods, of which one may be questionable.

The book is easy to read and should be read by anyone interested in the analysis of aluminum and its alloys.—A. E. PAVLISH.

Journal of the Electrodepositors' Technical Society.—

Vol. 14

Electrodepositors' Tech. Soc., London, 1938. Cloth, 5¾ x 8¾ in., 252 pages. Price 1 guinea.

In recognition of the need of electroplaters for application of the more advanced technical knowledge available today, the 26 practical papers in this volume, together with their discussions, present the more recent developments in commercial plating. Considerable space has been devoted to explaining and evaluating various methods of measuring thickness and testing electro plates, referring to drop tests, bend tests, magnetic tests and stripping. The methods are critically discussed in relation to practical use in specification plating.

Plant practice and experiences in nickel and bright nickel plating in England are treated in some detail. In the latter cases, the Schlötter, Weisberg and Stoddard, and the Hinrichsen processes are shown to have given satisfactory performance in manual, semi-automatic and fully automatic application.

Electro-refining of copper, the problem of patents, and anodizing of aluminum are summarized, and should prove instructive reading.

In general the material should be of interest to platers and engineers because of the practical aspect of the treatment of the subjects and the discussion of the various papers by men experienced in the plating industry in England. The American reader should probably keep in mind that the evaluation of product quality as related to production economics is no doubt based on somewhat different methods and factors than those that exist in the United States. The methods used in this country, not being widely known in England, apparently have led some authors to a misunderstanding of the quality of production plating in the United States.—C. L. FAUST

U. S. S. Carilloy Steels

Carnegie-Illinois Steel Corp., Pittsburgh, 1938. Cloth, 6 x 9 in., 214 pages.

This bears some similarity to handbooks dealing with alloy steels previously put out by Bethlehem, Republic, International Nickel Co., Vanadium Corporation of America and Climax Molybdenum Co. Large charts on hardenability, the S curve and grain size are included, and the discussion of these fundamentals is outstanding. That on machinability is also of interest.

The usual property charts for S.A.E. steels are included, together with bar charts of core properties of carburizing steels. Stainless steels are not included. A particularly valuable section is that dealing with the gradations within and between the compositions of the S.A.E. steels, in individual specifications of General Motors, Ford and Chrysler.

The ultimate purpose of handbooks of this type is to sell steel, and specifically the steels made by, or using the elements sold by, the firm that prepares the book. Possibly there comes in also the aspect of self-protection against complaints that would be avoided by more understanding of fundamentals and hence, more intelligent use by the purchaser. At any rate, the dissemination of sound technical information is considered so important that such handbooks have ceased to be mere catalogs and reiterations of the virtues of "Three Star Double Extra" brand, and contain not only data but discussions of metallurgical principles that are often far from being kindergarten subjects. These discussions must be brief, clear and correct, for the prestige of the firm is involved. Few text books are written with the care for correct phraseology that one meets in these books. Consequently, the student as well as the practicing metallurgist values them highly—and they deserve to be highly valued.—H. W. GILLETT.

Aluminum Bronze

Copper Development Assn., London, 1938. Cloth, 6 x 8½ in., 150 pages. Free to those "of responsible status and genuine interest."

This is another (Publication No. 31) of those authoritative little books on copper alloys issued by the British Copper Development Association. It has much the same form and arrangement as did "Copper in Cast Steel and Iron," which was published in '37. If we may expect an analogous publication on each class of important copper base alloy every year, a decided metallurgical need will be met. The "Alloys of Iron" monographs have accentuated the lack of similar treatment of alloys of copper.

The approach is an engineering rather than a sales-propaganda one. Limitations are pointed out as clearly as are advantages.

Starting with the equilibrium diagram, physical and mechanical properties of the straight copper-aluminum alloys are given in Chapter 1. Chapter 2 deals with α copper-aluminum and copper-nickel-aluminum alloys for cold working; Chapter 3 with those of duplex structure for hot working, and with their heat treatment and resulting properties. Casting alloys, corrosion-resistance, production and fabrication of sand, die and centrifugal castings, Durville pouring for ingots, hot and cold working, joining and machining, take up the next three chapters. A brief final chapter deals with industrial applications, though many of the 83 illustrations that were scattered through the previous chapters showed industrial uses of the materials there discussed. A bibliography of 211 references covering 1927-1938, and a summary of specifications, follow.

This "clear, concise, complete" monograph is a valuable addition to any metallurgical library. Its detached, judicial attitude, stating useful properties without flag-waving and with full recognition of drawbacks and limitations, might well be emulated by other groups who prepare the handbook type of publicity for their products. The metallurgical engineer who uses this will appreciate the spirit in which the facts are presented, as much as the facts themselves, for the un-named author recognizes that his readers are intelligent, reasoning beings who are repelled rather than attracted by the extravagant phrases so often found in publications of this sort. One would guess that the book was written by a metallurgical engineer without "benefit" of a rephrasing by an advertising man, for there is inherent evidence throughout of unflavored engineering truth.—H. W. GILLETT.

Metallurgy *(Metallurgie)*

R. Cazaud

Dunod, Paris, 1939. Cloth, 4 x 6 in., 328 pages. Price 25 fr.

Somebody must want a handbook of this nature since this is the 55th edition. However, the contents are sketchy and often out of date, only half a dozen pages of new or revised matter being any different from the previous edition. In a few tables of statistics, 1938 data have been included. As an example of the poor balance characteristic of the handbook, an alloy of 80 Ni, 14 W, 6 Zr is listed as a cutting tool while carbide tools are dismissed with one sentence to the effect that sometimes tools are made of tungsten carbide.

It would seem that anyone who had any need for a metallurgical handbook would need a better one than this, and that anyone having one edition of this would not want another for at least 5 years. At any rate, the English-speaking reader will not find it worth the cost.

Another Dunod handbook *(Automobile Handbook,* 27th Edition, 488 pages, 3¾ x 4½ in., 25 fr.) just published, has a metallurgical section of some 65 pages, consisting chiefly of a listing of various alloy steel compositions supplied by several French steel makers. In general, the comments made on the metallurgical handbook apply also to this.—H. W. GILLETT.

The William Campbell Fellowships

Through the bequest of the late William Campbell, for many years Howe Professor of Metallurgy at Columbia, there have been established the "William Campbell Fellowships" primarily for scientific research in the field of metals. These fellowships become available for the first time for the academic year 1939-40 for graduate study and research at Columbia University. They carry stipends up to $1200 per annum as determined by the Campbell Fellowship Committee.

Applications accompanied by certified transcripts of academic records, proposed research projects and proposed fields of graduate studies should be filed with the Dean of Engineering, Columbia University, New York City, before March 15, 1939. Announcements and application blanks will be forwarded to interested persons upon application to the same address.

A Powerful Magnet

The most powerful permanent magnet in the world, one that will lift nearly 1500 times its own weight, has been developed in the research laboratory of the General Electric Co. by W. E. McKibben.

The magnet weighs 1.85 grams, 1/250th of a pound, and has been made to lift 2750 grams in tests. About half the size of an eraser on the end of a pencil, it will lift a 5-lb. flatiron with ease. The new magnet is several times as strong as those previously made.

The magnet is made of a material known as "Alnico," an alloy of aluminum, nickel, cobalt and iron. It was first developed in the General Electric research laboratory as a heat-resisting alloy which resisted scaling and deterioration at high temperatures. Research on the magnetic properties of alloys of this type was later carried on by Prof. T. Mishima of the Imperial University, Tokyo, and General Electric perfected a process of heat treating by which the magnetic properties were more fully developed.

Alnico has been used in radios, motors, generators and other electrical equipment for some time, replacing electromagnets which require current. The new magnet developed by Mr. McKibben employs the same alloy as previously used, but utilizes a steel sheath around the Alnico pellet to direct the magnetic flux against the keeper or object being attracted. The steel jacket also protects the magnet against demagnetization when not in use.

Malleable Founders' New Activity

Through Robert E. Belt, secretary-treasurer, the Malleable Founders' Society, Cleveland, announces the recent appointment of James L. Cawthon, Jr., to its full time staff in the capacity of development engineer. A new activity of the society occasions the announcement. Included in this new service will be the furnishing of technical data to users of malleable castings, development of new uses for the material, and other services to users and Society members coming under the head of general product development engineering.

Enrique Touceda, professor of metallurgy, Rensselaer Polytechnic Institute, Troy, N. Y., author of numerous contributions to the literature of iron and steel metallurgy, and one of the outstanding metallurgical authorities of the world, is consulting engineer to the society.

James H. Lansing, shop practice engineer, has been engaged in the malleable iron industry in technical, production and executive capacities for the past twenty years. Mr. Lansing's activities are mainly in connection with maintaining quality standards.

James L. Cawthon, Jr., development engineer newly appointed, has been identified with the iron, steel and foundry industries for the past 19 yrs. His experience has included engineering, production, sales and advertising, and executive activities. He has been associated with Pittsburgh Electric Furnace Corp., General Motors Corp., the Bonney-Floyd Co., American Steel Foundries, and Continental Steel Foundries. In addition to general duties listed above, he will also carry on the society's cooperative educational work with technical schools in the country.

A. I. & S. E. to Meet in Birmingham

Fred M. Sturgess, chairman of the Birmingham section of the Association of Iron and Steel Engineers, has announced the official program for the annual spring conference of the association, which will be held in Birmingham, Ala., March 27 and 28. Mr. Sturgess, who is master mechanic and chief electrician for the Fairfield Wire Works of the Tennessee Coal, Iron and Railroad Co., states that the technical sessions will be held in the headquarters, the Hotel Tutwiler.

As customary, inspection trips will be conducted to plants in the area of this national meeting. Monday afternoon, a trip will be made through the plant of the American Cast Iron Pipe Co. Tuesday, the entire day will be spent inspecting the vast properties of the Tennessee Coal, Iron & Railroad Co.

Social activities will include a Luncheon at 12:30 P. M., Monday, in the Hotel Tutwiler. A. B. Haswell, assistant to the vice-president, Tennessee Coal, Iron and Railroad Co., will be the speaker. In the evening an informal dinner will be held, at which Robert Gregg, president of the Tennessee Coal, Iron & Railroad Co., will be the principal speaker.

Steel Institute Meeting on May 25

The forty-eighth general meeting of the American Iron and Steel Institute will be held at The Waldorf-Astoria, New York, on Thursday, May 25. Program of the meeting has not yet been announced. Attendance at all sessions of the meeting and at the banquet will again be restricted to individual members of the Institute.

● John R. Heckman has been appointed midwestern representative for The Electro-Alloys Co., Elyria, Ohio. He will make his headquarters at 122 South Michigan Ave., Chicago.

New Location for Alrose Chemical Co.

The manufacturing plant and laboratories of the Alrose Chemical Co. and Mark Weisberg Laboratories have recently moved from their former Providence, Rhode Island locations, 80 Clifford St. and 92 Printery St., to a new, enlarged factory at 180 Mill St., Cranston, R. I. The new plant, off Park Ave., has 40,000 sq. ft. of working space, with laboratories to accommodate 8 chemists.

The John P. Bonnett & Son Co., formerly owned by Mark Weisberg Laboratories, has been liquidated. Its operations in the electroplating of jewelry and novelties in precious metals have been discontinued in order that increased emphasis may be given by Mark Weisberg Laboratories to research and the development of new specialties for the metal and textile trades. Development of several new finishes is contemplated, also improvements in all methods of electroplating so that the demands for new styles and colors may be met more satisfactorily by manufacturing jewelers. At the new plant, a full line of synthetic chemicals for the textile industry, wetting agents, etc., will be produced as in the past.

Chrome-Magnesite Brick for Furnace Roofs

The recent Austrian development of a chrome-magnesite brick for open-hearth furnace roofs, ports and uptakes is the most important single advancement in open-hearth furnaces for many years, according to Lewis B. Lindemuth, consultant on steel production, New York. Last year he visited Germany and Austria to study this development and last fall he again went to Austria to see the latest improvements. He considers it important that all furnaces, now being built or projected, should take into account the probable change in the near future to basic refractories, so that provision can be made for such a change, without interfering with the immediate operation as a silica refractory furnace.

Bridgeport Brass's New Mill

Devoted exclusively to the production of brass, copper and copper-base alloys in sheets, rolls and strips, Bridgeport Brass Company's recently completed rolling mill is designed to utilize heavy cast bars in standard widths, with multiple slitting to provide any desired combination of widths.

The new mill, built as a part of a large expansion and modernization program, embodies in its design the straight-line production principle of materials handling.

The mill lay-out, developed by the company engineers, is planned so that the flow of production is uninterrupted and materials proceed in one direction up and down the four main bays of the building from the first breaking-down mills to the inspection and shipping of the finished material.

New Chairmen of A.I.M.E. Divisions

J. H. Nead, chief metallurgist, Inland Steel Co., Chicago, has been elected chairman of the Iron and Steel Division of the A. I. M. E. The new chairman of the Institute of Metals is R. H. Leach, vice president, Handy & Harman, Bridgeport, Conn.

● At the annual meeting of the Aluminum Association in New York, Charles B. Bohn, president of the Bohn Aluminum and Brass Corp., Detroit, was elected president to succeed Arthur Vining Davis who had been president of the Association since its formation in 1933.

Free Service Department

Replies to box numbers should be addressed care of METALS AND ALLOYS, *330 West 42nd Street, New York.*

POSITION WANTED: Electric steel melter, 9 years' experience Moore Rapid Electromelt furnaces, acid and basic processes. Laboratory experience. Able to take charge of melting and laboratory. Box MA-122.

POSITION WANTED: Powder Metallurgist. Four years' experience covering all phases from pilot plant production of powders and parts to pure research on fabrication and treatment. Graduate Chemical Engineering. Trained analyst and metallographer. Excellent references. Available immediately. Location immaterial. Age 25. Married. Box MA-123.

POSITION WANTED: Metallurgist, B. S. in engineering. Age, 30. Five years' experience in metallography, physical and steel analysis. For past 3 years metallurgist in charge of heat treat operations and laboratory testing in tractor and truck parts plant. Employed at present but available on 30 days notice. Box MA-124.

POSITION WANTED: Electrical and Metallurgical Engineer, M. S., 32 years. Broad experience: Ferro-alloys, electric arc and induction furnaces, automatic regulation, layout and maintenance; metallurgical processes. Excellent references, location immaterial. Box MA-125.

POSITION WANTED: Foundry metallurgist or melter metallurgist. B. Met. E. Melter, alloyed gray iron, one year; gray iron foundry metallurgist, one year; melter-assistant metallurgist, gray iron and high carbon steel foundry, three and one-half years. Experienced with operation and control of cupolas, Moore 'Lectromelt and Detroit Rocking Electric furnaces and the Brackelsburg furnace. Age 29. Married. Box MA-126.

POSITION WANTED: Professor of Metallurgy desires position for three months starting June first. The possibility of developing into permanent position of added interest. Ph. D. in physical chemistry and physical metallurgy. Four years of industrial experience and eight years of teaching experience in engineering schools. Will consider either teaching or industrial position. Box MA-127.

POSITION WANTED: Research Director. Executive engineer with outstanding record of widely used ingenious cost reduction methods, experienced in establishing better products from laboratory findings and coordinating new market uses in mechanical, electrical and chemical industries, is available to manage development program involving difficult processing, patent, and customer adaptation problems. Box MA-128.

POSITION WANTED: M. E. in engineering, major in metallurgy. Recent graduate with 18 months' non-ferrous experience. Will consider either industrial or teaching position. Box MA-129.

POSITION WANTED: Physical metallurgist. M. S. Age 26. Desires an opportunity in metallurgical development or control work. Good reference on past research experience. Box MA-130.

trends

by Edwin F. Cone, Editor

Lead in Steel

Is lead an alloying element in steel? This question has arisen because of the development last year of "Ledloy" which is discussed in the leading article in this issue. This is not fully answered but some significant trends are indicated, based on the research to date. Therefore it may be stated, say the authors, that lead is but an infant in the kindergarten of the alloying elements but, as regards screw stock, it is a lusty infant. They offer the hope that, as this infant grows and passes up through the grade and high schools, it may be graduated into an important alloying element in a much wider field such as the improvement in machinability of strong, heat-treated steels.

"Light" Steel Products

The trend in the American steel industry toward the manufacture of "light" steel products has been pointed out by the American Iron and Steel Institute. For the first 9 months of 1938, this type of steel—sheet, strip steel, wire products, tinplate, etc.—accounted for 45 per cent of the total output as against 42 per cent in the same periods during 1937 and 1936. This trend reflects the increased consumer demand for automobiles, farm and household goods, sanitary cans and similar products. The American capacity for strip steel production has expanded by leaps and bounds in recent years. In hot-rolled sheets and strip alone our output has doubled in 10 years—5,297,400 gross tons in 1927 and 10,735,000 tons in 1937.

Price Wars in Steel

Discussing the cessation late last year in the prospective price war in steel products, *Poor's Industry and Investment* says that "it is significant that cessation of the price war was largely a result of the unusual plea by important cussumers that quotations be restored to their former levels. These users saw that the entire industrial and business structure might be endangered by widespread uncertainty on the price of a product so important to our economy. It was realized that steel workers' wages would necessarily be reduced if price cutting continued unabated, and the market for users' products such as automobiles, would be curtailed." There was a reaffirmation of prices for the first quarter resulting in a sound price structure—a trend of decided general industrial benefit.

Open-Hearth Control

We were much interested in the announcement early this year of the development by the Steel Corporation of an equipment using an electric eye, or photo-electric control, as a means of keeping the temperature more uniform in the open-hearth furnace. It is claimed to be one factor in producing more uniform steel. We are reliably informed that all the new open-hearth furnaces built and put into operation last year have been more fully equipped with measuring, recording and controlling instruments than ever before. This all points to more complete control of open-hearth operations and probably better steel.

Steel Ingot Capacity

The ingot steel making capacity of the United States continues to rise. As of Dec. 31, 1938, the American Iron and Steel Institute figures this at 72,533,969 gross tons. A year earlier, or on Dec. 31, 1937, it was 71,065,640 tons. This is an increase of 1,468,329 tons or about 2 per cent. Most of this increase is naturally in open-hearth capacity. The trend in the increase in electric furnace capacity is interesting. Last year this capacity advanced over 15.5 per cent or from 1,331,124 tons to 1,540,255 tons. There must have been a substantial increase in the number of electric furnaces.

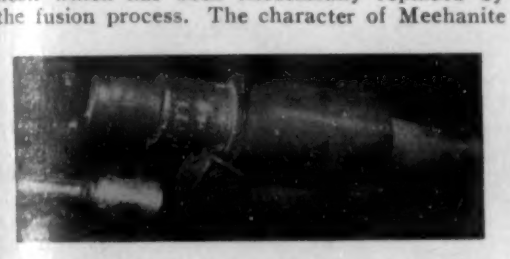
On the other side of the picture Bessemer capacity and that of the crucible process sharply declined.

Blast Furnace Capacity

Contrary to the trend in open-hearth steel ingot capacity in 1938, the capacity for producing coke pig iron declined from that existing at the close of 1937. At the end of 1938 the capacity was 49,252,120 gross tons or 407,480 tons less than the 49,659,600 tons on Dec. 31, 1937. This is somewhat surprising. One reason is probably found in the tendency to use more scrap in open-hearth charges than in earlier years.

Brass Die Castings

We referred last month to an address we heard on "Die Castings" by Charles Pack, vice-president, Doehler Die Casting Co. For some time we have been familiar with die castings of zinc, aluminum and magnesium base metals. Not many years ago, brass die castings were a new product. Mr. Pack stated that these had not been as successful as the others, due largely to the difficulty in finding a steel die that would have a long enough life. This problem is however nearing solution.



Exports of Scrap Steel

The exports of scrap iron and steel continued on a large scale in 1938. Data show that the total was over 3,003,500 gross tons which, while less than the 4,092,590 tons in 1937, is the second largest total on record. Japan is again the largest customer having taken about 1,400,000 tons last year as against 1,911,500 tons in 1937. Some contend that this trend is a menace to our supplies of raw material in case of war. The secretary of the Scrap Iron and Steel Institute states that no harm is involved in this movement, and offers data to prove his contention.

New Equipment and Materials

Rolls Repaired With Meehanite

A new method has been devised by Fulton Foundry & Machine Co., Cleveland, which permits the repair of broken roll necks by means of a special foundry burning technique. From 2 to 5 tons of Meehanite metal are used for each roll in order to make a good fusion to the roll body. Shown is a repaired back refiner roll used in a rubber reclaiming plant. In the foreground may be seen the broken roll neck which has been successfully replaced by the fusion process. The character of Meehanite

metal lent itself to the development of this process, and the fusion is carried out at a temperature slightly higher than the melting temperature of the parent metal in the rolls. So complete is the union that after grinding no dividing line is visible.

The roll shown is a 24-in. diameter by 36 in face back refiner roll used in conjunction with a somewhat smaller front roll; the rolls, in operation, being set close together and creating pressures of from 90,000 to 110,000 lbs. on each neck or journal. Bearing temperatures often reach 300 deg. F. due to friction resulting from a differential in speed of the rolls, which is usually 3 to 1.

The process has been successfully applied to 60 and 84-in. mill rolls, various refiner rolls, mixing, crusher, washer, and tin mill rolls, Gordan plasticator screws, hard rubber grinding rolls, and warming mill rolls.

Liquid Soldering Flux

"Special X" is the trade name of a new liquid soldering flux particularly intended for "difficult to solder applications", says the Industrial Service Laboratories, 915 W. Oklahoma Ave., Milwaukee. It is the result of two years' intensive research on soldering fluxes. It can be used on brass, copper, cadmium, stainless steels, zinc, monel, iron, and many other alloys.

Research was particularly undertaken to provide a better flux for builders and fabricators of alloy steel and Monel equipment but results have shown that it works unusually well in production or "line" soldering of toys, expansion valves, electrical controls, small pressure tanks, restaurant equipment, milk coolers, lighting fixtures, etc.

Lowered surface tension and good wetting power or flux cause quick and uniform flow of solder into all cracks and crevices.

Manufacturer will supply working sample and technical data upon receipt of request on your company letterhead.

Manufacturers are invited to send to the Editor items which are suitable for this Department. Illustrations are acceptable, preferably in the form of cuts no more than 2 in. wide.

A Direct Current Welder

A new direct current arc welding motor generator set, with a rating of 150 amp. at 25 volts, and having a range of adjustments from 20 to 200 amp. at 25 volts, has just been announced by Wilson Welder and Metals Co., Inc., New York City. Current control on this new welder consists of a 3-point current switch and a dial rheostat control for fine adjustment. It is stated that the smoothness and precision of this adjustment makes it possible always to get the right current, and greatly enhances the adaptability of the machine to all types of electrodes, from bare to heavily coated. Open circuit voltage is from 40 to 75 volts. The set will use electrodes up to 3/16-in. diameter. Standard wiring is for 3-phase, 220 or 440-volt, 60-cycle power supply.

Welding qualities claimed for this welder are a steady arc and quick voltage recovery, that it welds without current surges and without losing the arc when welding on thin sections. It is expected that these features will greatly reduce losses due to burning through, and also those due to the necessity for rewelding defects caused by arc interruptions.

The portable model, equipped with strong rubber tired casters, is 12 by 26⅛ in., stands 23⅝ in. high, weighs 338 lbs. The stationary model, without casters, weighs 8 lbs. less. The new welders are sturdily built for continuous production service, and attractively finished in yellow.

Magnesium Alloy Speeds Shipping

Industry is placing strong emphasis on the elimination of needless weight. This vital need for light-weight metals that provide strength, toughness and durability is being met by magnesium alloys. Last holiday season at the Jacksonville, Florida, terminal, with the help of this new metal alloy, the Railway Express Agency efficiently and expeditiously handled more than 2,500 carloads of express matter. Magnesium alloy was adapted to their use in the form of portable gravity conveyors, replacing the heavy steel conveyors, previously used.

The portable steel gravity conveyors, which had been used to a limited extent by the

Railway Express Agency, were limited in their usefulness due to their excessive weight. The conveyors in 10-ft. lengths had to be portable and when constructed of steel, the weight materially slackened their handling, hence did not increase shipping speed.

The theory of using some of the lighter alloys in order to get 10-ft. and 13-ft. sections which would be sufficiently light for one man to readily carry or move was developed. According to C. G. Peterson, chief engineer, several experimental sections were constructed of Dowmetal and used in service tests, the rollers, the through shafts and the 3-in. side rail with extruded channels all being made of Dowmetal. After an extended series of tests, it was proved conclusively that such development would be useful in many operations, such as loading and unloading to and from cars and street vehicles, and in sorting express matter for different destinations or consignees. To date more than a half-mile of these portable conveyors are in use.

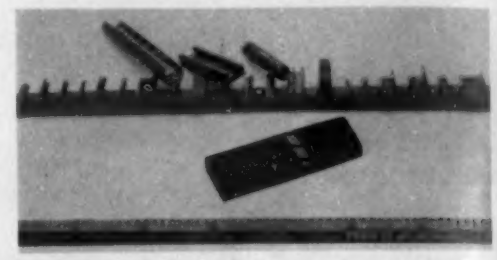
(Continued on page MA 192)

Chart for Recording Meters

A new, permanent chart for recording meters, impervious to moisture and unaffected by atmospheric changes, is announced by the Permochart Co., Pittsburgh, manufacturers of Permochart —the "Everlasting Recording Chart". This is the chart from which each day's recordings are easily removed by use of a damp cloth and the same chart is used over and over again.

The new, patented Permochart is formed of three sheets of acetate, laminated under tremendous pressure, with the chart design printed from precision plates on an inner, opaque sheet and laminated between two sheets of smooth, transparent acetate. The bond between laminations is made so close under the newly developed method of manufacture that moisture cannot penetrate and the all-acetate construction eliminates any tendency to separate or buckle due to atmospheric changes.

The manufacturer claims that the new Permochart is the most accurate ever devised, that shrinkage and expansion is reduced to a minimum and that, even under the most extreme atmospheric conditions, this accuracy will not be materially affected.



The new chart is obviously much more durable than ordinary paper charts or the original Permochart and, under normal conditions of usage, should be practically indestructible. The writing surface, though smooth and hard, is flexible. Recordings are uniform and clear. Damage due to pen penetration is entirely eliminated. Furthermore the chart does not require meter changes but is affixed and removed in the same manner as paper charts.

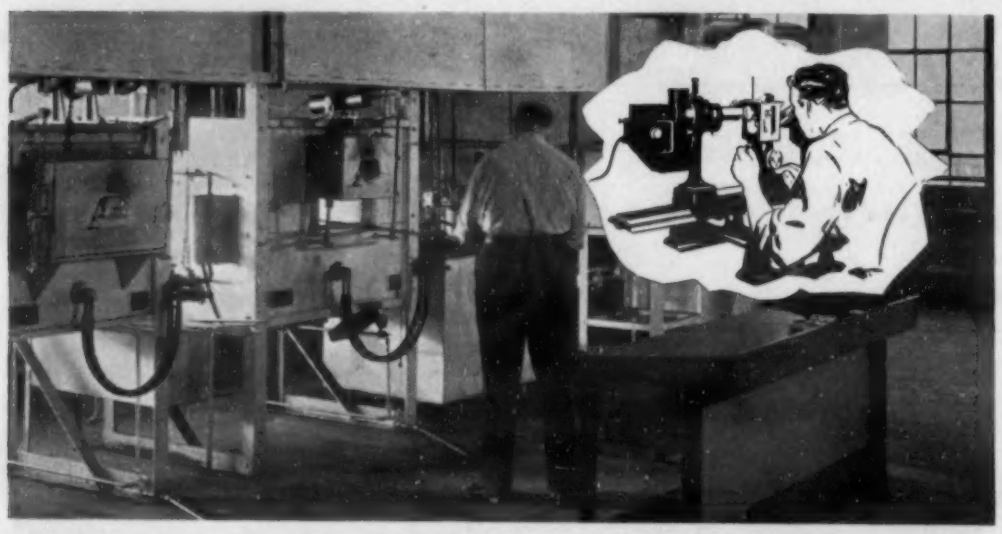
The Permochart Co. offers a comparison between the cost of a 2 yrs.' supply of paper charts and one Permochart (guaranteed to give 2 yrs.' service) which shows an indisputable saving of 75 to 80 per cent in favor of Permochart. Thus, if a manufacturer's recording meter chart bill reaches any proportions at all, he can immediately effect an appreciable saving without any investment beyond the cost of a 90-day supply of ordinary paper charts.

Minute Shapes in Metals and Plastics

Shapes in every conceivable design and thinness are now being made in metals and plastics for numerous industries, architects, designers, instrument-makers, inventors and other scientific workers who have long needed such precise shapes in their line of work. Because of their accuracy, these shapes are also ideally adapted to the construction of scale-true models. The new process by which these shapes are made was developed by Precision Shapes, Inc., 230 Park Ave., New York City.

"Precision Shapes," as they are termed, are of special significance in that they answer problems in design that have hitherto been impossible to achieve under the limited methods of extrusion, rolling or milling. Standard designs in brass are continuously kept in stock, but other designs, even extremely complicated in form, can be made to specification at short notice in a wide range of materials. With this new process the additional expense for dies is eliminated, with a resultant saving to the user. Another feature of this new process is

that Precision Shapes can be made in any length up to 24 ft.



The process by which Precision Shapes are made makes possible, it is claimed, the meeting of unusual requirements in design and actually begins its work where extrusion leaves off. For instance, angles 1/32-in. with a wall thickness of 0.010-in, Tees 1/16-in. with a wall thickness of 0.012-in., channels and square channels of the same minute size, slotted angles 1/16-in. thickness, I-beams 1/16-in. with a wall thickness of 0.012-in. are among the many standard items readily available. Any conceivable shape, undercut or decorative type of strips can be speedily made to specification. There is no limit down to 0.002-in. tolerance to the design in which these shapes can be manufactured. They challenge the ingenuity of both designer and engineer, as well as the attention of production men in every line of scientific and industrial endeavor. All shapes can be slotted in any number of openings, or they may be threaded or otherwise treated to meet special structural needs.

Where only limited quantities of extruded shapes are needed, usually die costs make the price prohibitive. In such instances Precision Shapes are not only more accurate than those produced by other means, but more economical to use.

In plastics, Precision Shapes have many important uses depending on the nature of the plastic material. Internally, many different shapes are used to hold glass, metal, etc., while also acting as a reinforcement for the plastics. Externally, special decorative shapes add beauty in addition to stiffening the structure and preventing warping.

Carburizing Salts

The Case-Hardening Service Co., 2281 Scranton Road, Cleveland, has folders available on request describing its new "CHS" Carburizing Salts for case-hardening. These salts are supplied in three types—No. 10 for producing a case up to 0.010 in.; No. 30, for up to 0.030 in.; and No. 70, which may be used for case depths up to 0.070 in.; or to increase the activity of either of the other two. They are intended to replace the highly poisonous cyanide baths commonly in use; and the makers claim greater stability in use, no corrosive action on the pots, no soft spots on the case, and no need for any other cleaning agent for the work except hot or cold water. It is also stated that owing to the fewer furnace-hours required for a given depth of case, and the fact that the product supplies its own heat-retaining "blanket" material, considerable heat-economy is also obtained.

"Hazards of hardening expensive tools have been eliminated."—

WELDON TOOL CO.

"Control over heat treating conditions (says Weldon Tool Co.) is maintained by microscopic inspection of hardened specimens in our modern laboratory. The 'Certain Curtain' furnaces have practically eliminated rejections after hardening. *Soft skin no longer forms; burning and blistering of fine tools are prevented; cost of cleaning and grinding is greatly reduced.* The hazards of hardening expensive tools in older types of equipment have been eliminated."

Harden high speed steels with maximum safety for maximum working life, by using "Certain Curtain", world's leading tool furnace. C. I. Hayes, Inc., Established 1905. 129 Baker Street, Providence, R. I.

ELECTRIC CERTAIN CURTAIN FURNACES

FOR 11 YEARS THE LEADER IN CONTROLLED-ATMOSPHERE HEAT TREATMENT

Rockwell Hardness Testers QR and QS

For those whose hardness testing requirements call for 100 per cent production testing of parts made in large quantity, or for testing a large percentage of their product, the "Model QR Rockwell" hardness tester and the "Model QS Rockwell" superficial hardness tester offer many advantages without any loss of accuracy in testing.

These motorized models are made in an 8 in. vertical capacity. The readings obtained are *identical* with readings obtained on Rockwell hand-operated machines, of which many thousand are in use, and the speed has been increased to a point consistent with obtaining accurate and reliable results. Specifications determined on the hand-operated models may therefore be met on these motorized testers. An extensive study of production hardness testing with light loads such as are used on the Rockwell tester indicates conclusively that speeding up the operation of the machine does not necessarily speed up in direct proportion the number of pieces that can be tested. Efficient handling of the work oftentimes can do more to increase the number of pieces tested than any amount of quickening operation of the tester itself.

The design of these motorized Rockwell testers is such that no time is wasted after the material is inserted in the machine and there is no lost time through idle cycles of machine when the specimen must be placed in position with care. Readings are absolutely independent of variations in thickness of pieces tested. There are not many applications where motorized equipment will be a decided advantage to the user, but for such applications the Q Model Rockwell and Rockwell Superficial hardness testers will give genuine Rockwell numbers on a machine which conforms to the high standards of precision and accuracy that are built into the hand-operated models. With the Q model you can test your product to the same hardness limits as previously and it is not necessary to sacrifice the quality of your inspection for the sake of making more tests per day.

A Powdered Soap for Wet Working Copper

A new powdered soap for the wet working of copper and brass known as "Nopco Soap L", has been announced by the laboratories of the National Oil Products Co., Harrison, N. J.

The new soap, described as clean, white, and free from odor, has been tested in the company's laboratory and by practical mill men in outside plants. This soap is highly concentrated, resistant to rancidity, economical, and versatile.

Nopco Soap L is recommended for use in the following wet working applications: (1) Drawing or stamping of copper and brass shells, (2) Drawing of coarse yellow brass wire, (3) Drawing of intermediate yellow brass tubes, (4) Drawing of coarse, hard bronze wires.

Colalloy—New Alloys

The Colonial Alloys Co., E. Somerset, Trenton Ave. and Martha St., Philadelphia, offers a new alloy "Colalloy." It is an alloy of manganese, magnesium, silicon, aluminum (copper and chromium where necessary), and some lesser proportions of other metals. Depending upon the use for which it is intended, it is made up in a variety of sizes, hardnesses, strengths, endurance limits and other physical and mechanical properties. For example, ultimate strength may range from 12,000 to 61,000 lb. per sq. in., yield strength from 3,900 to 4,900, Brinell hardness from 20 to 110. Melting temperature is 1,210 deg. F. and thermal conductivity at 100 deg. C. in c.g.s. units ranges from 0.27 to 0.51.

The complete range covers more than 30 alloys each suited to a particular purpose. It is claimed they will not rust, are nontoxic and have high thermal factors, and will not taint or damage the most delicate foods. Material is made in all gages, sizes and forms of sheets, strips, flats, plates, seamless tubing, fittings, structural shapes, bolts, nuts, etc.

Bronze Bearings

In another step toward meeting the requirements of industry, the Horace T. Potts Co. announces the addition of a line of bronze products to its already complete line of iron and steel products. The new line includes all sizes of standard bronze machine bearings and precision bronze bars, both solid and cored, as produced by the Bunting Brass & Bronze Co., Toledo, Ohio. This new service—which includes consultation and technical assistance—was inaugurated March 15. Stocks are now completed in the Potts warehouse, ready for immediate delivery. Literature and catalogs, giving full description and dimensions of the new bronze line, can be obtained by writing to the Horace T. Potts Co., East Erie Ave. and D St., Philadelphia.

The Potts company already handles a large stock of Anaconda free-cutting brass rods as part of its complete warehouse service covering everything from machinery, stainless and structural steels to non-ferrous metals, welding accessories and home and industrial fencing.

(Continued on page MA 194)

you can join your metal parts ECONOMICALLY, NEATLY, SECURELY and CONTINUOUSLY

By the ELECTRIC FURNACE BRAZING METHOD

The assemblies are loaded on a conveyor at charging end of the furnace as shown below

. . and carried through the furnace and discharged—securely joined—clean and bright

Small assemblies weighing only a fraction of an ounce as well as large intricate assemblies weighing several pounds are neatly and securely joined in numerous designs of continuous and batch type copper brazing furnaces — Built by The Electric Furnace Co., Salem, Ohio.

Four E. F. brazing furnaces are shown on this page—The two pusher type furnaces above are brazing large automotive and refrigerator assemblies. The two belt conveyor furnaces at left are brazing automobile fan pulleys. Other E. F. brazing furnaces are handling practically everything from small metal radio tube parts up to large assemblies weighing 50 pounds or more.

Send for Circular on the Brazing Process.

ELECTRIC FURNACES FUEL FIRED

Investigate the brazing process for your products. We will be glad to give you complete information, put samples of your products through one of these furnaces to show you the results you can expect, and give you an estimate on the cost of the equipment to handle your production, together with operating cost, etc.

The Electric Furnace Co., Salem, Ohio

Gas Fired, Oil Fired and Electric Furnaces---For Any Process, Product or Production

An Indicating Gage

Designed for use where endurance as well as accuracy is a prime factor, an indicating gage with an all-welded steel construction has just been introduced by The Foxboro Co., Foxboro, Mass. The all-ferrous construction of the "Model P" gage affords perfect protection on applications where there are fumes or vapors corrosive to bronze. The absence of solder and bronze eliminates the risk of fire hazard.

A special Chapmanized steel of high Brinell rating is employed in the pinion, segment, arbor and connecting link of the new Model P. To eliminate binding or raggedness in pointer motion and to insure a smoothly-operating movement, the segments and pinions used in these Foxboro gages are not blanked in, but instead have milled teeth. The movement plates, columns, links and shoulder screws are made of stainless steel.

Threaded rings, equipped with gaskets, make the Model P gage completely moisture-proof and vapor-proof and also serve to retain the extra-heavy glass firmly in place. All pointers and dials are of stainless to prevent corrosion and discoloration.

The 270 deg. bourdon spring incorporated in this gage makes possible the use of springs double the range of the gage without increasing the movement multiplication or decreasing the accuracy. Chrome-molybdenum steel is used for ranges up to and including 1,000 lbs.; above that, nickel steel tubing is used.

The Model P test gage, available in ranges from 0-15 lbs. to 0-10,000 lbs., is guaranteed accurate within ½ of 1% at any point on the range. The Model P refinery gage, furnished in ranges from 0-60 lbs. to 0-2,000 lbs., and the Model P hydraulic gage, with ranges from 0-600 to 0-10,000 lbs., are guaranteed within 1% of their total range. Further information about this new Model P indicating gage may be obtained by writing to The Foxboro Co., Foxboro, Mass.

Control that CASE DEPTH with efficient–economical

Du Pont CASE HARDENING Salts

Shallow or deep cases . . . you can obtain the right case hardening salt from du Pont to meet your individual requirements.

These salts are uniform with a guaranteed cyanide content. They provide a wide operating range and the utmost in economy.

Plan to visit the du Pont exhibits at the GOLDEN GATE INTERNATIONAL EXPOSITION in San Francisco and at the NEW YORK WORLD'S FAIR

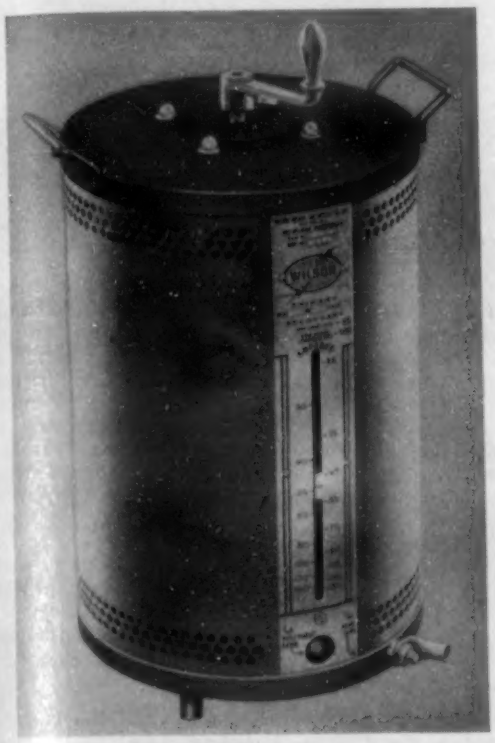
Sectionalized Heat Treating Boxes

U. S. Patent No. 2,144,374, issued Jan. 17, 1939, to Walter G. Hoffman and assigned to The American Brake Shoe & Foundry Co., covers the device shown which is manufactured by the American Manganese Steel Division, Chicago, Heights, Ill. Annealing, carburizing and heat-treating boxes suffer rather brutal treatment generally; and, in particular, from high furnace temperatures, variable temperatures during the heating cycle, and differential heating. They are bound to burn out, crack or break, sooner or later, but the Flexbox design is calculated to make this "later." "Flexboxes" are made of Amsco alloy, in the grade best adapted to the particular requirements.

The ends, sides, bottoms and covers are cast separately. The ends are made with vertical grooves into which fit corresponding tongues on the side castings. There are matched slots in both tongue and groove for holding pins to prevent relative vertical movement of the parts, but this does not hinder adequate horizontal movement. Distortion or cracking, resulting from alternate heating and cooling, is avoided in the Flexbox by providing sufficient clearance between tongue and groove to allow for expansion and contraction. Corrugations in the castings are said to give greater strength under high temperatures. Light cast covers, corrugated or flat, with or without legs, are used to replace the old style bottoms cast integral with the boxes. Special bottoms in which the edges fit into grooves in the lower edges of the end plates are available where the complete box with its contents is to be lifted.

The features of the Flexbox are: 1. They mechanically avoid the stresses set up by contraction and expansion resulting from rapid heating and cooling, but do not allow any appreciable gas leakage at the vertical joints. 2. Thinner and sounder castings result from this design as each section is a simple casting, much smaller than a one-piece box. 3. Should a section of the box fail, it is easily and quickly replaced at a fraction of the cost of replacing an entire box. 4. As in the case of all Amsco alloy parts, X-rays of check castings minimize the possibility of placing defective castings in service.



Vibration-Proof Indicator Pyrometer Controller

A vibration-proof "Celectray Indicating Potentiometer," Celectray Model V, has been developed. Photoelectric detection of the position of a light-beam reflected from the mirror of a moving galvanometer provides an undiminished high sensitivity of the original Celectray Indicating Controller combined with practically instantaneous response. A new damped photoelectric circuit has been developed which does not respond to abnormal disturbance of the light-beam. So far as vibration is concerned Celectray Model V acts somewhat as a filter, that is, the action of vibration upon the galvanometer cannot effectively be transmitted through the instrument to the control device such as a magnetic contactor. This controller can be mounted rigidly in a vibrating panel along with the contactor or next to a drop hammer without regard for the possible effect of vibration. Vibration does not even cause the primary relay within the instrument to operate nor does it interfere with normal action of the controller. It is claimed that the instrument is sensitive to temperature change but not to vibration. All the advantages of the previous successful Celectray models have been retained such as the safety shut-off feature, 15-in scale, 0.1% accuracy and indications by a brilliant white, red or green line of light on ground-glass, visible at a great distance.

Arc Welder For Light Gage Sheet

The Wilson Welder and Metals Co., Inc., New York City, announces a new arc welder of 100 amp. rating at 30 volts for light sheet metal welding and other light work requiring low current and fine control. The new machine is of the alternating current, transformer type, and designed especially for use with heavily coated electrodes. Standard wiring is for single phase, 220-volt, 60-cycle power supply, but it can be furnished for 440-volt supply if desired. Open circuit voltage is 65 volts.

A calibrated scale on the front of this welder indicates the adjustment throughout the range of the machine, which is from 25 to 150 amperes. This adjustment is made continuously by rotating a crank at the top, and

because the circuit is not broken there is no need to stop operations and open any connections while a change is being made. The continuous nature of the adjustments makes it possible to tune the current exactly to suit the thickness and welding characteristics of the material being welded and of the electrode used.

Alternating current welders of this size have been found to give the best performance when electrodes made especially for A.C. welding are used. Therefore the company recommends Wilson No. 520 with this model. It will accommodate diameters up to 5/32-inch.

Enclosed in a sheet metal housing 16½ in. in diameter and 24 in. high, weighing 145 lbs., the new welder is a compact and mobile unit. The whole construction has been designed to the complete safety and durability required in production welding departments. The welder meets the requirements of the latest standards of the Underwriters' Laboratories, Inc.

Thor Core Binder

A newly patented process, whereby milk solids are used as a binder for the sand cores of foundry castings, has resulted from several years' operation of a research fellowship by The Borden Co., New York, at Mellon Institute, Pittsburgh. The product, called "Thor Core Binder," is now being produced commercially by Casein Co. of America, division of the Borden company. It is used in both core and facing sands. The binder has the feature of burning freely and quietly. This contributes toward a smoother surface on the casting, and produces a core which is quickly and easily shaken out. Thor cores are hard and strong, and yet very collapsible under heat of the casting. Several important manufacturers have made quantity use of this process over a period of years, and it is now considered to be entirely practical and ready for general use.

Chemically Treated Buffs

An interesting method of making buffs last longer and stand up better against abrasive wear is a chemical treatment perfected by the Hanson-Van Winkle-Munning Co., Matawan, N. J., manufacturers of electroplating equipment and supplies. These buffs are made of two types of square count cloth called Economy and Tractor. The buffing cloths, as they come from the loom, are passed through a chemical bath. The wear resistance developed by this chemical treatment is further increased by the carefully balanced construction of the buffing textile. It is stated also that the treated buffs absorb polishing composition better, giving improved cutting and coloring action on the product being buffed.

The chemicals used for treating the buffs include a hygroscopic element whose purpose is to absorb moisture from the air, fixing it in the cloth and giving a conditioned sheeting at all times.

Improved Trimming Machine

In the early part of last year the Quickwork Co., Chicago, announced a new stamping trimming machine, (May, 1938, MA332). Important improvements have been made on this machine. It is arranged now to operate the machine with an electric eye.

In the previous design the operator actuated the pneumatic air cylinder which opened and closed the rolls with a foot pedal control. In the present design, this is done by means of a photoelectric-relay. This has proved very convenient and has resulted in increased production. After the operator loads the machine, he moves his right hand horizontally through the beam—this permits the operator to stand firmly on both feet at all times. The electrical equipment to accomplish this is not involved and is easily housed within the base of the machine. The arm carrying the electric eye can be swung away from the table and rolls if convenient in changing setups.

FROM ORE TO METAL

The Story of St. Joe Electro-Thermic Zinc—Number 2 of a Series

Man-made Caverns

"Underground photograph of a stope in the Balmat Mine of the St. Joseph Lead Company in St. Lawrence County, New York State."

The limestone is so solid that no timbering is necessary. The veins have a dip of about 45 degrees. Distance from foot wall to hanging wall at places, is over 60 feet, and the man-made caverns left after blasting out 400,000 tons of rock a year grow to gigantic dimensions. From these stopes the zinc in the ore starts its long journey, traveling by gravity to the underground chutes and ore pockets, eventually being converted into St. Joe electro-thermic zinc at the Josephtown, Pennsylvania, smelter of the St. Joseph Lead Company.

Pressure Fan

Outstanding feature of the Sturtevant "Axiflo Pressure Fan" is the ability to operate against wind resistance or the resistance of filters, baffles, discharge conduits etc. Blades are so pitched that regardless of wind direction or velocity or fan location, there is no appreciable effect on air delivery.

Principal use of the Axiflo Pressure Fan is the moving of large volumes of air against resistance, or where space requirements call for a rugged yet highly compact unit. The ease with which it may be installed, and the comparatively low initial and operating cost makes it well adapted for almost any industrial application, including heating, ventilating, cooling, mechanical draft, drying, humidifying and fume, vapor or dust removal.

The Axiflo Pressure Fan has a mechanical efficiency of 79% and the ability to overcome system resistance up to 1½ in. w. g. It possesses the economical operation advantages of the axial flow type of fan combined with the performance of the centrifugal fan. Unlike the ordinary propeller fan, the Axiflo Pressure Fan is ruggedly constructed. Casing is heavily built and fitted with streamline inlet. Wheel is of solid and integrally cast heat-treated aluminum alloy which is non-corrosive under the action of most acid content chemical fumes. The Axiflo Pressure Fan is available either for direct connected motor drive or for belt drive, and arranged for wall, floor, platform or ceiling installation. Eleven sizes are available, ranging from 18 to 60 in. diameter with capacities up to 75,000 cu. ft. per min.

For complete details including capacity tables, corrosion resistance tables and dimension diagrams write for catalog 444, B. F. Sturtevant Co., Hyde Park, Mass.

Guaranteed 99.99+% Pure

WHEN you choose Anaconda Electric for the base of Zinc die castings, you are certain of obtaining uniform, dependable metal. For every slab of Anaconda Electric Zinc is electrolytically refined and guaranteed 99.99+% pure.

Anaconda Electric Zinc is supplied in 50 lb. slabs clearly marked "Anaconda Electric 99.99+%." Whenever you use this well-known brand, whether in small quantities or carload lots, you may be sure that *every slab is uniform in quality... is by analysis 99.99+% pure.* 80992

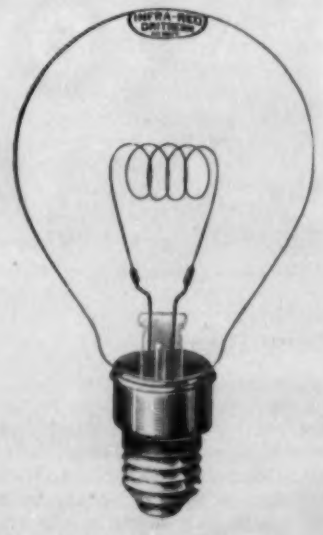
"Kennametal"

A new, reliable, hard carbide alloy for machining tough metals such as steel, heat treated up to 500 Brinell, which combines roughing and finishing in one operation, is now being supplied under the trade name of "Kennametal" by the McKenna Metals Co., 158 Lloyd Ave., Latrobe, Pa. The basic ingredient is tungsten-titanium carbide ($WTiC_2$) and the new alloy may also be used in machining Monel metal, malleable iron, cast iron, brass, bronze, aluminum, etc.

Kennametal is available in three standard styles of blanks from which tools may be tipped



by the user, or it may be purchased in other than standard blanks. The manufacturer also offers an assortment of 18 styles of Kennametal tipped tools for operations such as reaming, boring, tapping, milling, gaging, etc. The illustration shows Style No. 11 tool, tipped with Kennametal, and the unretouched inserts show the smooth finish of Kennametal form-tooled bar stock (magnified three times) as compared with surface machined with high speed steel, or tungsten carbide.

Kennametal permits 2 to 6 times greater cutting speeds than those of high speed steel and 10 to 50 times as many pieces per grind of tool. It is harder than the hardest tool steel. The manufacturer has prepared a new, descriptive booklet and will be glad to furnish complete information on request.

Infra-Red Ray Lamps for Radiant Drying and Heating

Dritherm is the name under which the newly improved "Nalco Infra-Red Ray Lamp" will be marketed. These lamps, made by the North American Electric Lamp Co., Saint Louis, have been especially manufactured for radiant drying and heating purposes. They represent the final development of over 4 years' research and practical application in a number of the country's largest plants, including automobile plants, where they are used for paint baking.

Long burning life in proportion to high efficiencies obtained, uniformity of filament materials, as well as placement of carbon filament within the bulb, and rugged construction to minimize breakage—are several features claimed for these lamps.

Full details, sizes, prices, etc., as well as material on the application of radiant drying and heating installations may be obtained by writing North American Electric Lamp Co., 1014 Tyler St., Saint Louis, Mo.

JOHN ATTWOOD, SECTION EDITOR

Classified Grinding Research. LEONARD ANDREWS. *Bull. Inst. Mining Met.* No. 409, Oct. 1938, 25 pp. Standard units of measurement necessary for free interchange of results of grinding research between countries are proposed. The rise of temperature in a wet grinding mill is due mainly to 2 causes: (1) Molecular 3 stretching and shearing of the strained suspending medium surrounding the solid particles and (2) molecular agitation in particles not fractured by blows received. There is an appreciable reduction of shear resistance with increase of temperature—40% over 10° F. for one pulp. At constant temperature, shearing losses are directly proportional to interfacial surface area of the pulp. Pulp density has little effect on shear resistance other than an indirect contribution to the interfacial surface area. Tests on a commercial batch pan mill grinding pottery flint confirmed these 4 laboratory findings. High-velocity directional streams are generated in classifiers by the momentum of the incoming feed. This can be entirely avoided through the use of the vortex diffuser feed, which is described. Air bubbles in classifier feed carry over particles much larger than theoretical; their effect can be nullified by use of submerged intakes to classifier overflow discharge pipes. Aggregates can be dis-associated by a water vortex a few inches above a sand surface. Accurate elutriation of particles above 100 μ can be accomplished using this principle. The best working head 5 for discharge of sand from classifiers is 2-9 in. of H_2O. At less than 1 in., velocity of discharge is so reduced as to destroy fluidity; at more than 10 in., coring is liable to occur. Since normal head on a spigot discharge from a cone classifier is 6-10 ft., the top should be closed and the normal head balanced by a syphon overflow pipe (drawings given). AHE (1)

Gold Concentrates Defy Cyanidation. J. G. HART. *Chem. Eng. Mining Rev.,* Vol. 31, Oct. 1938, pp. 9-11. A study was made to determine whether concentrates at the Maude and Yellow 6 Girl Mine at Glen Wills, Vic., could be treated at the mines to avoid heavy freight costs. It was found that (1) only part of the Au in the concentrates is available to amalgamation and cyanidation methods. A maximum recovery of about 54% of the Au was obtained by straking and cyanidation at —200 mesh with a cyanide consumption of 5.6 lbs./ton. (2) The lowest residue value obtained in laboratory experiments was 32 dwt. Au/ton by cyanidation at —10 micron. (3) Roasting followed by regrinding to —200 mesh, straking and cyanidation resulted in 56% 7 extraction of the Au, the final residue value being the equivalent of the straight cyanidation residue. (4) A relatively large amount of sub-microscopic or unrecognizable Au was present in the arsenopyrite and pyrite of the cyanidation residues. Only complete disruption of the particles by chemical means can lead to complete extraction of the Au. WHB (1)

Metallurgical Developments at Mercur, Utah. W. J. FRANKLIN & VIRGIL MILLER. *U. S. Bur. Mines Tech. Paper* 588, 1938, 42 pp. Descriptive. The Au in the oxidized ores is readily soluble in cyanide solutions and is treated in a continuous counter- 8 current decantation cyanide plant. The Au in the basic ores is not amenable to straight cyanidation, owing to the presence of C, cyanicides and soluble salts. Good extraction was obtained in the laboratory by roasting followed by cyanidation; mill tests were unsatisfactory owing to high costs and inability to treat the calcine which formed a gel in the thickeners. The ores can be treated by a flotation-cyanidation process. A Au concentrate is made con- 9 taining some cyanicides and the C in the ores. The tailings can be washed free of soluble salts and then treated in the regular cyanide circuit. Costs are considerably less than by any other known method. The tailing dumps can be treated by the same methods. AHE (1)

Read "TRENDS" . . .

on page MA250 for the latest news, its significance, and what it means to metallurgical engineering, as seen by E. F. Cone.

Research on the Influence of Preliminary Treatment on the Flotation of Bituminous German Copper Ore of the Mansfeld and Niedermarsberg Type (Untersuchung über den Einfluss einer Vorbehandlung auf die Schwimmfähigkeit bituminöser deutscher Kupfererze vom Typ Mansfeld und Niedermarsberg) H. MEFFERT. *Metall u. Erz,* Vol. 35, No. 3, 1938, pp. 55-58. Research. Flotation tests were made on carbonaceous shales containing small amounts of Cu. The Mansfeld type contains about 84% gangue, 7% carbonaceous matter and about 9% metallic sulfides with a Cu content of about 3%. Pb and Zn sulfides are also present. Niedermarsberg ores contain greater amounts of quartz and pyrite and smaller amounts of Cu and carbonaceous matter, otherwise the ores are much alike. The Niedermarsberg ore, in spite of the presence of the carbonaceous matter, can be floated to a concentrate of 20% Cu without any preliminary concentration. Mansfeld ores produce a thick and voluminous froth that entraps gangue material and prevents a concentration of over 10% Cu in spite of numerous supplementary treatments. The reason for this behavior is attributed not so much to the carbonaceous matter or the surface properties of the ore but to the manner of reduction. From the evidence of the concentrate and tailings, which indicate very fine particles in the tailings and larger grains in the concentrate, it appears that the Mansfeld ore is ground too fine in the ball mill for satisfactory flotation and grinding to a minimum of about 15μ is recommended. Dry grinding probably can be most advantageously employed. The correctness of these conclusions must be verified by further work. PCR (1)

Use of an Alternating Pressure Field in the Wet Preparation of Ores (Anwendung eines Druckwechselfeldes in der Nassaufbereitung) HELMUT KRAINER. *Metall u. Erz,* Vol. 35, No. 18, 1938, pp. 471-474. Research. After a short discussion of the theoretical and experimental fundamentals and the physical properties of ultra sound waves in liquids, called "alternating pressure field," a study of a dusty, high SiO_2, Fe-Mn ore was made that previously could not be separated by known means. By exposure to the high frequency sound waves followed by gravity separation, the ore can be separated into Fe containing quartz grains and a clayey, fine-grained material that consists mostly of metal hydroxides. Mn and Fe recovery is 96.5 and 85%, respectively. PCR (1)

The Getchell Mine—New Gold Producer of Nevada. ROY A. HARDY. *Eng. Mining J.,* Vol. 139, Nov. 1938, pp. 29-31. The Getchell mine in Humboldt Co., Nev., is now cyaniding 500 tons of oxidized and W-bearing ore and 150 tons of sulphides daily, with preliminary roasting for the latter ore. A flowsheet of the 600 ton mill is shown. The oxidized ore can be cyanided directly, whereas 50% of the Au in the sulphides is refractory and cannot be cyanided. All sulphide ores are given a low-temperature roast of 1500° F. for 1 hr. and 15 min. prior to cyanidation. WHB (1)

The Condition of Refractory Gold in Lake View and Star (Kalgoorlie) Ore. N. I. HASZARD. *Proc. Australasian Inst. Mining Met.,* No. 108, Dec. 31, 1937, pp. 253-324. Descriptive. Au in flotation concentrates occurs free, as tellurides and associated with pyrite (20-30% of heads). The last is refractory, is not freed even at 5 microns, and causes high losses in the residue. The free Au and tellurides are dissolved readily by cyanidation or bromo-cyanidation. A quick roast at high temperatures adversely affected extraction. A low temperature roast finished at high temperatures gave good results. Extraction was improved by acid treatment of the concentrate or by treating clean pyrite; the interfering substance seems to be $CaCO_3$. AHE (1)

Electrostatic Separation. III. The Process, Recently Improved, Now Invites Wider Application. HERBERT BANKS JOHNSON (Ritter Prod. Corp.) *Eng. Mining J.,* Vol. 139, Dec. 1938, pp. 41-45. The possibility of reversal of polarity of the electrostatic charge on many of the common economic minerals facilitates their separation. Improvements of the Huff process of electrostatic separation involving reversal of polarity are noted, also the results of such separation on a number of minerals. Estimated costs are given for a representative example. WHB (1)

2a. Ferrous

Microscopic Investigation of Krivoi Rog Sinter. YA. GRECHNI. *Teoria i Pract. Met.*, No. 7-8, 1938, pp. 23-31. In Russian. Research. The petrographic structure of sinter made under different conditions was determined. The magnetite-fayalite eutectic was observed in all samples, though in different crystalline forms; the relation between magnetite and fayalite varied within wide limits, not only because of supercooling, but because the magnetite present was precipitated from the solid solution of magnetite and fayalite. Ferrous oxide does not exist here as an independent component and is replaced by a wüstite-fayalite eutectic. A small amount of hematite-fayalite eutectic was frequently observed, principally in place of the secondary hematite. This suggests that hematite in eutectic mixtures is of a secondary origin. No quartz-fayalite eutectic was found, even after long heating. The finely divided matrix in which fayalite-magnetite crystals are imbedded appears to be a triple eutectic SiO_2-Fe_2SiO_4-Fe_3O_4. No FeO-Fe_3O_4-Fe_2SiO_4 eutectic was found. An intergrowth of hematite along the octahedra planes was very pronounced, and can be explained by the decomposition of hematite-magnetite solid solution. The coefficient of refraction of the fayalite varied between 1.82 and 1.92 (1.877 for pure fayalite). This can be attributed to the presence of solid solutions with ferrous oxide and magnetite. (2a)

Blast Furnace Instrumentation. F. N. HAYS & L. P. MIKALOFF (Carnegie-Illinois Steel Co.) *Instruments*, Vol. 11, Dec. 1938, pp. 297-300. Survey. The following instrument applications essential to regular and economic operation of a modern blast furnace are discussed at length: (1) Blast temperature, (2) automatic hot blast temperature control, (3) automatic combustion control for stove burners, (4) stove stack temperature, (5) stove dome temperature, (6) stock line recorder, (7) top temperature, (8) blast pressure, (9) blast volume and (10) humidity and atmospheric pressure. The moisture carried into a 1000-ton furnace with the blast may vary from 72 gals./hr. in the winter to 1100 gals./hr. in the summer. The value of the fuel gas leaving the top of a 1000-ton furnace is approximately $400,000 per annum. Air-conditioning of the blast may save 10% C, increase the furnace production and improve its regularity. Determination of the dust content of the top or fuel gas by light transmission or photo-electric principles, automatic flow proportioner, continuous determination of CO and CO_2, or of their ratio, determination of the Fe and slag temperatures are still in their infancy. EF (2a)

Study of Hot Stoves Used with a Standard Blast Furnace. S. DROBYSHEVSKI. *Teoria i Pract. Met.*, No. 7-8, 1938, pp. 6-11. In Russian. A detailed study covering 20-day operation of a 2-pass 3-zone hot stove was used as a basis for calculating its thermal efficiency. The stove was kept on gas until its dome temperature reached 1200° C., and on air until the temperature dropped to 750° C. The greatest losses are connected with surface radiation, particularly around the combustion shaft and on the dome. Better insulation is advocated for reducing these losses by 20-25%. An improvement in thermal efficiency can be expected when the free cross-section of the checker work in multizone stoves is always reduced on passing from the upper to the lower zone. (2a)

2b. Non-Ferrous

Recovery of Precious Metals and Production of Selenium and Tellurium at Montreal East. C. W. CLARK & J. H. SCHLOEN (Canadian Copper Refiners, Ltd.) *Metals Tech.*, Vol. 5, Oct. 1938, T.P. No. 982, 22 pp. Descriptive. Blister cakes from Hudson Bay Mining & Smelting Co., Flin Flon, Manitoba, and commercial anodes from Noranda Mines, Ltd., Noranda, Quebec, are refined at Montreal East. Both of these bullions have unusually high Au, Se and Te contents. The average assay of raw slimes produced from domestic and Noranda anodes is about Cu 40%, Ag 3600 oz./ton, Au, 800 oz./ton, Se 22% and Te 3.7%. A Ag refinery, and methods used for recovering Se and Te, are described in detail. JLG (2b)

Cathodic Polarization During Electrolysis of Molten Salts. S. A. PLETNEV & V. N. ROSOV. *Zhur. fiz. khim.*, Vol. 11, May 1938, pp. 641-645. In Russian. Original research. Preliminary measurements of the polarization during electrolysis of molten $PbCl_2$, using a cathode of liquid Pb, or of solid C, are described in detail. The measured potential is the sum of a relatively small polarization voltage and a much greater voltage of purely ohmic character. With a C cathode, the potential varied depending on the direction of the change of current density. For the principal measurements an oscillograph permitting the polarization voltage and ohmic voltage to be measured separately, was used. Pure molten $PbCl_2$ or a eutectic mixture of KCl and LiCl with various amounts of $PbCl_2$ or $CdCl_2$, were used as electrolytes. The polarization as depending on current density and the $PbCl_2$ or $CdCl_2$ content of the molten mixtures, at 500° C., were determined. The deposition of Pb from pure molten $PbCl_2$ took place at the equilibrium potential, in contradiction to the findings of Karpachev & Poltotoralskaya (*Zhur. fiz. khimii*, Vol. 6, 1935, p. 966) and Karpachev & Rempel (*Zhur. fiz. khimii*, Vol. 8, 1936, p. 134), which are ascribed to their incorrect experimental procedure. In the mixed electrolytes, the polarization increased but very little with the current density, and decreased with increasing $PbCl_2$ or $CdCl_2$ content. The cathodic polarization was perceptible at 0.6 and 1.5 mol. % $PbCl_2$, but was absent at 8 and 16 mol. % $PbCl_2$; whereas it attained 20 millivolts at 1 mol. % $CdCl_2$ (thus being about 3 times greater than at 1 mol. % $PbCl_2$) and was still measurable (5 to 2 millivolts) at 23 to 47 mol. % $CdCl_2$. The results indicate that, in the case of $PbCl_2$ mixtures, the cathodic polarization is of the concentration type, *i.e.*, it is caused by a deficiency of Pb ions on the cathode owing to their insufficiently great rate of diffusion; whereas, in the case of $CdCl_2$ mixtures, it is probably caused by an insufficiently great rate of dissociation of the complexes present in the molten mixture. ORS (2b)

Effect of Solution Concentration in Electrodeposition of Manganese. S. M. SHELTON & M. B. ROYER (Bur. Mines) *Trans. Electrochem. Soc.*, Vol. 74, 1938, Preprint No. 33, 12 pp. Original research. A small pilot plant was operated to study the production of electrolytic Mn from ores. MnO_2 ores were reduced by city gas to Mn^{++}, leached with dilute H_2SO_4 + $(NH_4)_2SO_4$ solution and the resulting solution purified by removing Fe, As, Co and Ni. Pb anodes and 17% Cr steel cathodes were used, with canvas separation diaphragms. The fresh solution fed to the cathode compartment during operation contained 25 g./l. of Mn; pH, 7.2-7.6. The Mn content of the catholyte was 10 g./l., and pH 9.0-9.2. The anolyte contained 3-6 g./l. of Mn and 25-35 g./l. of H_2SO_4. The cathode current efficiency was about 50%. Power used was 3.6 kw.-hr. per lb. of Mn produced. The voltage-current density relationships of baths with varying Mn content of the feed solution and $(NH_4)_2SO_4$ content of the bath, were studied to determine the most economically desirable bath. The mutual solubilities of $MnSO_4$ and $(NH_4)_2SO_4$, are limited and too concentrated a solution must be avoided to prevent crystallization. A high Mn content of the feed solution results finally in a high acid content of the anolyte, which increases the conductivity of the cell. With a feed solution of 40 g./l. Mn, and current density below 3 amp./dm.^{2}, increase in $(NH_4)_2SO_4$ concentration above 125 g./l. does not materially increase the cell conductivity. AB (2b)

Influence of Coke, Temperature and Time on the Reduction of Zinc Oxide (Einfluss von Koksart, Temperatur und Zeit auf die Reduktion von Zinkoxyd) C. F. BRENTHEL & I. A. LEROUX. *Metall u. Erz*, Vol. 35, No. 7, 1938, pp. 173-174. Research. At 1000° C., reduction was 81.5 and 97.0% complete after 1 and 3 hrs., respectively, using lignite coke, and 41.5 and 48.5% using coal coke. At 950° C. recovery was only 72.1% after 3 hrs. and 98.5% at 1100° C. using lignite coke. PCR (2b)

Copper-smelting Plant Remodeled for Direct Smelting. LEONARD LARSON (Nev. Consolidated Copper Corp.) *Metals Tech.*, Vol. 5, Oct. 1938, T.P. No. 981, 11 pp. Descriptive. In 1932 the Cu smelter at McGill, Nev. was remodeled to send a charge of wet flotation concentrates to the reverberatory. The procedure of using the raw concentrate instead of roasted material proved satisfactory. The present plant is described in some detail. A matte containing approximately 30% Cu is produced. Preparation of Pure Metals (Die Darstellung reiner Metalle) CECIL H. DESCH. *Vorträge der Hauptversammlung 1938 der Deutschen Gesellschaft für Metallkunde, V.D.I. Verlag, Berlin,* 1938, pp. 1-5. Original research plus review. The difference between Al of extreme purity and slightly contaminated Al is remarkable. In the light of atomic distribution, the effect of impurities is difficult to explain. Because of surface tension, the dissolved element must be present in a different (mostly higher) ratio at the grain boundaries than in the rest of the mass. Highly pure Al, like Pb, recovers from cold work at room temperature. Al can be produced in a purer state on a large scale than in the laboratory. Spectroscopically pure Zn of 99.995% and Pb of 99.999% purity are available. Electrodeposition has been abandoned in favor of chemical preparation for Fe. After powder-metallurgical conversion, this high purity Fe has a Brinell hardness of 42, contains about .002% Si, .0015% S, .001% P, .0006% Ni and spectroscopic traces of Cu, Cr, Al, B, Ca and Mn. The latest determinations yielded .00045% C and .0005% O. Remelted electrolytic Cr is, in spite of traces of O, spectroscopically pure; its melting point is 1830° C. Absorption of N causes the hardness to increase drastically, and the melting point drops to 1580° C. at the eutectic point. Purest, brittle, metallic bright Mn is obtained by distillation and analyzes 0-0.004% Si, 0.003% Fe, 0-0.001% P; its melting point is 1247° C. Si is purified by chemical means and contains 0.02% Fe, 0.02% Al, 0.009% Ca, 0.006% insolubles. Pure Ni and Co are obtained by reduction of their oxides with C or H. Further distillation of purified Ni carbonyl is also applied. Further progress on the preparation of pure Mo and W along powder metallurgical lines is reported, and an automatic recording equipment for thermal analysis and melting point determinations is described. EF (3)

New Resistance Melting Furnaces with Graphite Rod Heater Units (Neue Widerstands-Schmelzöfen mit Graphitstabbeheizung) OTTO GENGENBACH. *Vorträge der Hauptversammlung 1938 der Deutschen Gesellschaft für Metallkunde, V.D.I. Verlag, Berlin,* 1938, pp. 97-98. Descriptive. A tilting drum furnace is provided with a graphite resistor rod located at its axis. A current of several thousand amps. is employed to heat the graphite rod to about 2,000° C. The terminals are water-cooled and at one end suspended freely to permit expansion. Up to 100 kw., the furnaces are single phase. The graphite rod burns up slowly and its diameter is reduced to half its original size after 6-8 melts of steel cast at 1650° C. However, in comparison with the arc furnace, the graphite rod consumption is only about 1/5, owing to the neutral furnace atmosphere. About 800-1000 kw.-hrs./ton and 250-300 kw.-hrs./ton respectively, for steel and bronze are consumed. Chips and scrap can be easily melted. The losses are small, again because of the neutral furnace atmosphere. Carburization of the melt does not take place. Compared with modern high frequency and arc furnaces, the following advantages are claimed: Lower initial cost; applicability of furnace for different metals, from steel to Al; simple construction and operation; small space; no parts to become excessively worn, and long life of furnace lining. The slag is hot and fluid, retains no metal and desulphurizes more readily. EF (3)

High-frequency Electric Furnaces. F. R. SMEDLEY. *Electrical Rev.,* Vol. 123, Nov. 4, 1938, pp. 644-645. Survey. High-frequency furnaces can be divided into those in which a motor generator is used and those of the spark-gap or thermionic tube type. The former are far more efficient and are preferred for most commercial purposes. The chief advantage of spark-gap type over motor-generator type is that any frequency can be obtained from the converter by suitable design of furnace coil, while a motor-generator set works at one frequency. Spark-gap equipment is also more suitable for obtaining the very high frequencies required for very small furnaces, such as those used in laboratories and for melting small amounts of high temperature metals and alloys. Small furnaces are used chiefly for melting Pt, Au and Ag commercially; making alloys where freedom from C is essential and thorough mixing is required, such as special Ni-Fe alloys; and making alloys of the W carbide group. Since the first commercial high-frequency furnace for making high-grade steel was installed, many have been installed, ranging up to 7 tons in size. Maximum capacity has not been reached yet. In earlier stages, provision of a suitable crucible and construction of a sufficiently strong outer casing tended to limit size. Now linings are made by fritting dry powdered lining material placed around a metal crucible-shaped former inside the furnace coil. Steel outer casings are now used on larger furnaces. Casing is shielded from induction by surrounding operating coil with a magnetic shield made of standard transformer Fe laminations. MS (3)

Internal Stresses in Castings. CHARLES W. BRIGGS (Steel Founders Soc. of America) *Welding J., N. Y.,* Vol. 18, Jan. 1939, Suppl., pp. 22-27. Suggests that some of the problems of welding are analogous to those encountered in the foundry, notably the problems of shrinkage and internal stresses. The material presented is mainly a review of published information. Prior to 1925 there was very little information on the mechanics of the formulation of casting stresses. During the past years most of the literature on the subject of casting stresses has been devoted to the relieving of this stress, and to such subjects as annealing temperatures, holding times and amounts of residual stress. Certain test castings, however, have been studied and from these a general idea of the nature of the stresses involved can be obtained. The primary source of internal stresses in castings results from contraction stresses. In 2 hindered contracting castings, acting under like conditions except for cooling rate, the fastest cooled casting will build up the highest stresses. All abrupt changes in section, sharp corners, casting irregularities and hot spots due to temperature gradients are potential positions of stress concentration. It is possible that small tension stresses of 500-1000 lbs./in.^{2}, as developed by contraction, are responsible for hot tear formation. 21 references. CEJ (3)

How Is Octopus-like Graphite Formed in Cast Iron? ICHIRO IITAKA & RUIZO SHIOTA. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Nov. 1938, Abstract Suppl., pp. 49-50. In English. Original research. The authors classify the structure of graphite formed in cast Fe as follows: Flake, eutectic, lump, octopus-like and rosette graphite. The so-called octopus-like graphite is formed with the lump graphite as the head and several legs of flake graphite attaching to it forming an octopus-like pattern. In the present paper, a study was made of the conditions under which the octopus-like graphite is formed. Test pieces were made by varying melting temperature, casting temperature, melting time and the percentage of C. Microscopic examination showed that it is the C content that has the greatest effect on the formation of the octopus-like graphite. In a pig Fe, containing 3.5% C, 2.5% Si, 0.68% Mn, 0.48% P and 0.027% S, the octopus-like graphite formation was absent on dilution with pure Fe and on depressing the C content below about 3.4%. With higher C contents, the formation occurs very frequently. Raising the melting temperature tends to suppress the formation. EF (3a)

Investigation of a Rimmed Steel Ingot. A. BOLOTOV & I. SOBORNOVA. *Metallurg,* Vol. 13, Oct. 1938, pp. 12-18. Practical. The steel tested contained 0.07% C, 0.33% Mn, 0.059% P and 0.030% S. It was deoxidized with Fe-Mn, and some Al was added before pouring. Tests were made to determine the extent and distribution of slag inclusions, and the liquation of the admixtures. The inclusions varied from 0.08% to 0.5% and consisted of finely dispersed complex oxides, complex Fe and Mn sulphide, and silicates with varying amounts of MnO, FeO, and also Al_2O_3. Liquation of the admixtures and inclusions was observed. The chief defect of the ingot was the large amount of slag inclusions. These may be decreased by regulating the air volume at the end of the blow to give the smallest amount of FeO in the metal. The slag should also have a minimum of FeO. BZK (3a)

Some Unusual Aspects of Malleable Iron Melting. A. L. Boegehold (Gen. Motors Corp.) *Trans. Amer. Soc. Metals*, Vol. 26, Dec. 1938, pp. 1084-1121; *Metal Progress*, Vol. 34, Nov. 1938, pp. 557-562. Campbell Memorial Lecture. Suggestions are made as to the possible control of graphitization in cast irons by varying contents of moisture and Fe oxide. Moist air bubbled through a laboratory induction furnace melt for 8 min. gave a gray casting, but when steam was used for 4 min. the fracture was completely white (analysis in both cases was C + Si = 3.79%). Further tests showed that ordinary air at normal humidity had strong power to retain carbide during solidification. Fe oxide in ladles used in the casting of partly gray Fe produced mottles small in size. Moisture and H were found to have a positive power to overcome graphitizing influence of increased C and Si. The prevention of contamination by solid Fe oxide is more important to the production of a white fracture with high Si and C than is the presence of moisture. With low C plus Si the presence of solid Fe oxide causes a gray fracture. Paradoxically Fe oxide acts as a graphitizing agent during solidification, and as a carbide stabilizer during annealing. The presence of Fe oxide makes the Fe more difficult to anneal, which is contrary to the characteristics that would result if increased mottling tendency were produced by the addition of some graphitizing agent, such as Si or Cu. CWH (3a)

Contribution to the Study of Pig Iron for Treating in the Converter (Contribution à l'Étude de la Fonte d'Affinage à Traiter au Convertisseur) P. Thierry. *Rev. Mét.*, Vol. 35, Oct. 1938, pp. 425-439. Comprehensive review. The 3 principal factors affecting the quality of the Fe are: (1) Chemical analysis; (2) physical heat; and (3) viscosity. The tendency has been to decrease the Si and Mn contents to about 0.15% and 1%, respectively. P is kept at about 1.7%. The main effect of the C is on the viscosity. Viscosity is difficult to measure; but the related property castability can be determined by casting a spiral 8 mm. in diameter and 3 m. long and measuring the length of the spiral actually obtained. Mn and P do not affect the fluidity greatly, but Si and C are very important. The fluidity increases with C up to the eutectic point, then decreases with further increase in C. The superiority of the eutectic composition is most marked for low temperatures. The castability increases with Si up to 0.3%, then goes through a minimum at about 0.5% Si, a second maximum at 0.75%, a second minimum at 0.95%, then gradually increases up to the eutectic composition after which it rapidly decreases. JZB (3a)

Instrument Firing. E. T. W. Bailey (Steel Co. of Canada, Ltd.) *Steel*, Vol. 103, Dec. 5, 1938, pp. 54-55, 73-74. Describes installation of automatic control on an open-hearth furnace at Hamilton works of author's company. Furnace, of the McKune type, was built primarily to use coke-oven or mixed coke-oven and blast-furnace gas. There are also separate burners for auxiliary high-pressure coke-oven gas. Gases are fed cold direct to furnace ports, and all checker chambers are used to preheat air only. Among instruments which do not control are those for recording temperature of fuels as they arrive at furnace; gas pressures; flow of each gas to furnace; volume of combustion air being supplied; furnace pressures; and temperature of gases leaving the 4 regenerator chambers as well as at inlet and outlet of waste-heat boiler. Of these, the fuel flow-meter is probably the most useful. The most important controlling instruments are those for controlling air-gas ratio or combustion; furnace pressure; roof temperature; and automatic reversals. Combustion control has reduced fuel consumption 500,000 B.t.u, per ton over manual operation. MS (3a)

Furnaces Operate on Clean Oil. E. H. Carruthers (Goulds Pumps, Inc.) *Foundry*, Vol. 66, Nov. 1938, pp. 30, 87. Practical description of brass founding at Goulds Pumps, Inc., with special reference to the use of fuel oil for the furnaces. Oil burning system maintains steady melting speeds and flame conditions, which are reflected in the quality of castings and fuel economy. Records show that melting 85-5-5-5 brass and raising to a temperature of 2200° F. takes an average time of 50 min. Fuel consumption averages 24 gal./100 lbs. P-bronze brought up to a temperature of 1900° F. averages 35 min. Fuel consumptions are 1.7 and 1.2 gal./100 lbs. VSP (3b)

Manganese Bronze Propellers. *Shipbuilder & Marine Eng. Bldr.*, Vol. 45, Oct. 1938, p. 553. Descriptive. The cement molding process (Randupson process), in which a mixture of silica sand, cement and water is used in place of green or dry sand and loam, is described with reference to its application for the manufacture of high tensile brass (ship) propellers. Castings produced by the process are close grained and denser and therefore more resistant to corrosion and erosion, as well as more true to pattern, due to the rigid nature of the cement sand mold. JWD (3b)

Preventing burn-in of mold and facing materials in pouring white hot metals...

THE MERIT MARK OF METAL — TAM METALLURGICAL ALLOYS

HOW A TAM PRODUCT INSURES CLEAN CASTINGS OF HIGHLY ALLOYED STEELS

The burning in of mold and facing sand where metal is poured at abnormally high temperatures is a constant source of increased cleaning costs. This is particularly true of highly alloyed steel castings—and is accentuated where the casting has fine detail such as internal threaded cores.

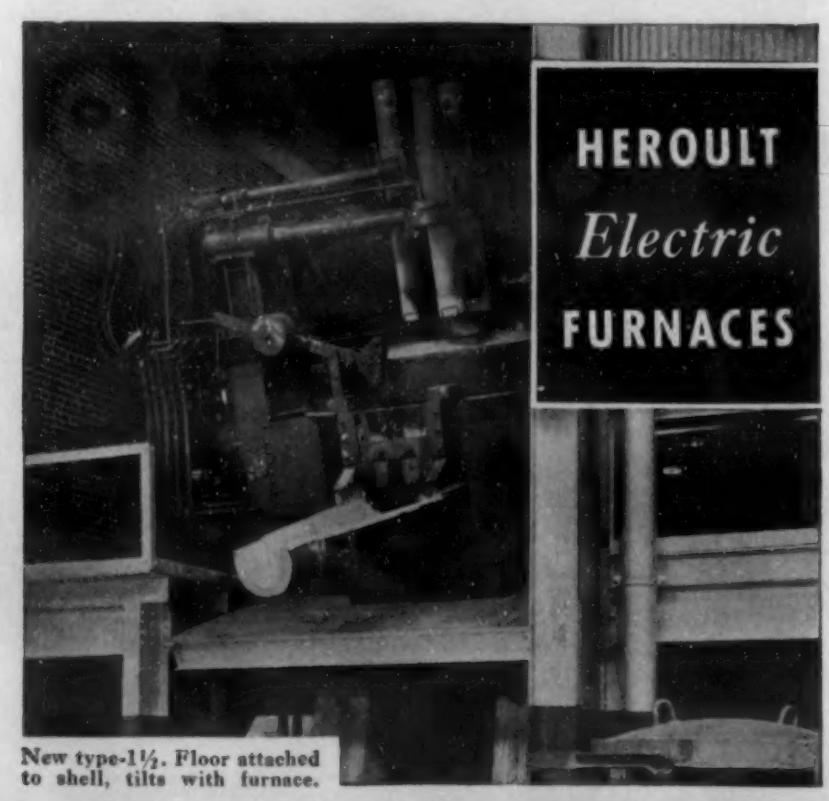
TAM Foundry Zircon Sand offers a practical method for preventing embedded sand, and the subsequent labor of chipping and cleaning. Highly resistant to extreme pouring temperatures, TAM Foundry Zircon Sand does not warp, requires a minimum of venting, yields clean, smooth castings with practically any type of metals—nickel-chrome steels, 18-8 stainless steels, in fact, with any of the highly alloyed steels... Can be used for the entire mold or as a facing sand, backed by ordinary sand... Has high reclamation value.

TAM Foundry Zircon Flour, used as a mold wash where ordinary flours tend to burn in, is another valuable adjunct to better foundry practice. Full particulars on request. Titanium Alloy Manufacturing Company, Niagara Falls, N. Y., U. S. A.

Look to TAM for better metals

MOLTEN IRON TEMPERATURE

FERROTEMP



Accurate temperature by immersion of grey and white iron in ladles.

Temperature range 1900 to 3200° Fahr. Economical in cost and use.

WRITE TO

HARRY W. DIETERT CO.

9330 Roselawn Avenue
Detroit, Michigan

New type-1½. Floor attached to shell, tilts with furnace.

USE them for efficient melting and refining of all kinds of ferrous materials by either basic or acid process—including alloy, tool and forging steels, iron and steel castings. Any capacity from ½ ton to 100 tons; removable roof, chute, machine or hand charging.

1 **Light-metal Sand and Permanent Mold Castings** (Leichtmetall-Sandguss und-Kokillenguss) GEORG MECKBACH. *Maschinenbau Betrieb,* Vol. 17, Dec. 1938, pp. 633-635. Practical. Principle of the 2 methods is outlined. When casting into sand molds, the grain of the sand shows on the surface. The permanent mold reproduces only its metal structure; the surface is practically smooth. Some sand particles will always stay in the surface of a sand casting, which is detrimental to machining. Because the "skin" of chilled castings is very thin allowances for machining can be as small as 0.5-0.75 mm. as compared with 1-2 mm. for sand castings; tolerance of ±0.1 mm. for small parts, ±4% for larger ones can be maintained by metal molds. Deviations between the individual parts can be avoided on chilled castings since 2 the mold parts are rigidly connected (hinges, etc.), with consequent saving on machine tool readjustment. The high heat conductivity of the iron or steel mold has a favorable influence on the structure. Too drastic a quench is prohibited by preheating the mold to 300°-400° C. The grain becomes finer and the surface becomes denser, with increase in resistance to corrosion; it can be oxidized more readily by the Eloxal-process; it improves its safety under high air, water or gasoline pressures (up to 20 at.); machining properties are improved, the tools are saved, accuracy 3 increased. The cost for Fe or steel molds is 50 to 10 times as high as for sand molds. They are chosen, therefore, for quantities above 500-1000 pieces, in which cases their use is more economical, in addition to the improvements outlined. Certain pieces are not suited to chill casting. Although the molds for chill castings have to be made with great care, the amount of spoilage and the size of lugs and risers are greater in sand mold casting. RPS (3b)

4 **Core Making in the Brass Foundry.** N. K. B. PATCH. *Foundry,* Vol. 66, Nov. 1938, pp. 31, 82. Practical discussion of characteristics and use of cereal and other H_2O soluble binders. Cereal binders may be mixed with a variety of sands that break down under relatively low temperatures. Where binders are used with a large proportion of molding sand added to usual core sand binders, or beach sand, resulting core has very smooth surface and imparts satisfactory surface to castings of Al-base alloys, Zn-base alloys and the like. Amount of H_2O to be added for preparing sand where H_2O-soluble binders are used varies with different kind of 5 binders. Best baking temperature for the cores is 350° F. Ample venting should be provided, and vents should be led to part of core print from which gases may escape through mold. Glue-bonded cores are used only under extreme conditions. Cores made with rosin or pitch binders show reasonable permeability if properly baked. With large cores, free venting from the center is advisable. Loam cores in brass foundry are required only when large castings are to be made. Includes some general rules to be observed in core making. VSP (3b)

6 **The Application of the Söderberg Electrode in Aluminum Furnaces** (Die Anwendung der Söderberg-Elektrode in Aluminiumöfen) M. SEM. *Aluminium,* Vol. 20, Dec. 1938, pp. 844-847. Practical. The electrodes are made of the same raw materials as ordinary C electrodes, but each consumer mixes them himself and they are baked during the process in the furnace in which they are used; the baking of the electrodes is done by the waste heat of the furnace, in contradistinction to the finishing of the whole electrode in other types of electrodes before their use. The electrode 7 is usually subdivided into 10, 12 or even more single electrodes, so that new, half used up and almost entirely burnt up electrodes are found side by side in a furnace. Some furnace types are described for metallurgical purposes and for the production of cryolite. Ha (3b)

8 **The Application of Artificial Core Binders in the Non-ferrous Metal Foundry** (Ueber die Anwendung künstlicher Kernbindemittel in der Metallgiesserei) *Giessereipraxis,* Vol. 59, Oct. 23, 1938, pp. 439-442. Why the application of core binders in German non-ferrous metal foundries is not so advanced as in Fe foundries is discussed. In describing the particular case of the production of valve heads, the considerable advantage derived from the use of core binders is shown. The application of pure quartz sand cores with oil core binders is not advised for non-ferrous foundries. GN (3b)

9 **Pores in Die Castings and Their Elimination** (Poren in Spritzgussteilen und ihre Vermeidung) J. GERBER. *Tech. Zentralblatt prakt. Metallbearbeit.,* Vol. 48, Aug. 1938, pp. 580-582; Sept. 1938, pp. 653-654. Practical. The tensile test values given for die casting alloys were obtained on specially cast tensile test bars. These strengths are not often attained on the actual casting, owing to the unavoidable presence of pores. Practical examples show how designer and die caster may closely approach the maximum strength by proper design and casting. EF (3b)

10 **Magnesium Foundry Practice.** W. C. DEVEREUX (High Duty Alloys, Ltd.) *Iron Age,* Vol. 142, Dec. 22, 1938, pp. 25-27. Abstract of paper read at Polish International Foundry Congress and originally published in Foundry Trade Journal. See *Metals and Alloys,* Vol. 10, Jan. 1939, p. MA 20R/1. VSP (3b)

4·WORKING

Forging, Rolling, Drawing, Extruding, Punching, Stamping, Shearing and Machining.

S. EPSTEIN, A. W. DEMMLER AND H. W. GRAHAM, SECTION EDITORS

Researches on the Deep-drawing Process. SHINJI FUKUI. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Oct. 1938, pp. 1422-1527. In English. Extensive original research. The author calculates a new relation between the drawing force and the stresses induced in a blank. He explains qualitatively the dependence of the drawing force on the shape of die and other factors, and points out that experimental measurement is the only way to determine the drawing force. He constructed an experimental apparatus using piezo-electricity of 2 quartz crystals to record continuously both drawing and holding forces. Experiments are made on plain and on redrawn Fe and Al blanks. Deformations and strains induced in the blank were measured. The experimental results refer to drawing and redrawing of circular cylindrical shells. The thickness of the blank is 0.5 mm. and the punch 18 mm. The forms of punch and die are considered to be very important. The author holds that conical dies should be employed to reduce the drawing force in order to facilitate the working and to obtain results of high quality. The various factors involved, such as thickness, annealing, temperature, lubricant, die clearance, drawing speed, etc., are exhaustively studied and the results presented in 47 tables and 62 illustrations. EF (D-4)

Surface Phenomena in the Cold Working and Recrystallization of Metals (Phénomènes Superficiels dans l'Écrouissage et de la Recristallisation des Métaux) GEORGES-A. HOMÈS. *Bull. Classe Sciences Acad. Roy. Belgique,* Vol. 24, Ser. 5 (3), 1938, pp. 147-158. Original research. The recrystallization of mild steel and Zn was studied microscopically and by X-rays. The metals were submitted to tensile stress or to polishing, or to both. Attention is focused on the type of stress, distribution of stress, presence of discontinuities and previous history of the specimens. Cold working in tension propagates from the surface into the interior regions of the metal. Polishing produces a superficial cold working. Recrystallization begins at the surface and extends into the interior. The shape of the new crystals are often masked by the contour of a previous crystallization. The hypothesis that the recrystallization centers are those parts where the stress has been greatest, is confirmed. For the definition of the state of surface of a metal, a combined study by microscopy under ordinary and polarized light and by electron diffraction is urged. EF (E-4)

On the Theory of the Origin of Rolling Textures in Face-centered Cubic Metals. M. R. PICKUS & C. H. MATHEWSON (Yale Univ.) *J. Inst. Metals,* Vol. 64, 1938, Advance Copy No. 821, 22 pp. Theoretical. A view is developed that not only accounts for all of the rolling textures that have been observed in face-centered cubic metals, but also assigns to each a relative degree of importance. The textures listed in order of their stability as developed by the analyses follow, where the direction indicated the direction of flow and the plane the plane of compression: [112], (1-10); [001], (100); [001], (110); [111], (-1-12); [101], (010); [101], (101). 17 references. JLG (E-4)

Practical Notes on Allenite Cemented Tungsten Carbide Tipped Cutting Tools. *Edgar Allen News,* Vol. 17, Dec. 1938, pp. 266-269. Descriptive review. The properties of the sintered W carbide material used for tools are described, and a very comprehensive table is given for cutting velocities, shapes and angles of the cutting tips, and finishing velocities for steels, cast Fe, non-ferrous metals and several non-metallic materials, such as glass, porcelain, plastics and marble. Ha (G-4)

Press Tools for Non-ferrous Metals. Piercing, Swaging and Impact Extrusion. R. KIRCHNER. *Metal Ind., London,* Vol. 53, Dec. 2, 1938, pp. 537-538. The most serious problem confronting the press tool engineer is the determination of the number and sequence of operations and proper application. The progressive pierce, notch, form and shearing tool for connecting strip; the 7-stage progressive tool for Al cup, the perforating tool for brass cup, the swaging tool for brass spindles, and the impact extruding tools for metal containers are described. These are all examples of press tools for medium or large quantity production. For small production jobs the major problem is balancing tool cost and holding total expenditures per piece at minimum. A few of the usual methods of approaching this problem are by simplification of orthodox type of tools, eliminating hardening, using castings for forming and drawing tools, standardizing types of tools, tool units and component parts and by employing tools of original or unusual design. 4a. Ferrous

Forged Steel Rolls. J. R. ADAMS & H. L. WILSON, JR. (Midvale steel Co.) *Iron Steel Engr.,* Vol. 15, Dec. 1938, pp. 48-67, 73. Practical. Steel rolls are forged from big-end-up ingots of electric or acid open hearth steel. Rigid heating cycles are followed in heating roll ingots for forging and in subsequent anneal to obtain the best possible structure. After preliminary machining, the rolls are given a pre-hardening treatment consisting of various quenches and draws, dependent upon the composition, size and purpose of the rolls. This treatment is checked by microscopic examination. The rolls are next finished machined; wherever possible sharp corners, thin sections, re-entrant angles, large changes in section and deep grooves are eliminated. Rolls are heated for hardening in specially designed furnaces and are quenched in air, oil, water or other solutions using specially designed fixtures for the protection of journals, shoulders, wobblers, keyways, fillets and champfers during cooling. Rolls are stress relieved after hardening in air furnaces, oil baths, salt baths and electric furnaces. Hardness is determined with a sceleroscope; Monotron and Rockwell tests are made on smaller rolls. Remaining machining is completed and the rolls are finish-ground. Successful grinding is accomplished only after careful application of proper wheels, grinding speeds and cuts, grinding compounds, etc. Grinding wheels should be soft and free cutting, otherwise excessive heating results and the roll may be burned. Bad chatter, pronounced transverse lines, slight out-of-roundness cannot be removed with a succeeding fine grit wheel. Touching the face of a stationary roll with the revolving grinding wheel may cause a grinding burn that may result in roll cracking or spalling. Etching with 7% nital solution darkens the burned areas; since tempered martensite is blackened, the unburned area remains white. Regrinding and re-etching are continued until all traces of the burning are removed. Too heavy grinding or the use of too hard a wheel may cause grinding checks and onion-skin spalling. Accidents in rolling frequently play an important role to subsequent roll failures. The heavy reduction of thick metal may cause the burning of the faces of rolls. Careful preheating of rolls before rolling operations avoids failures from rapid heating of the roll face from heavy reductions. Preheating the coolant used prevents too steep a temperature gradient, which causes high tangential stresses and may cause cracks. Overheated journals may cause severe spalling on the ends of the bodies adjacent to the necks. Care should be exercised in the storage of hardened steel rolls. Applications for forged rolls are discussed. CBJ (E-4a)

The Selection of Forging Materials. W. NAUJOKS (Steel Improvement & Forge Co.) *Ind. Heating,* Vol. 5, Oct. 1938, pp. 914-916; Nov. 1938, pp. 1016-1022; Dec. 1938, pp. 1114-1116. A general survey of the ferrous and non-ferrous metals used for forging; their composition, effect of Mn, Si, S, P, Ni, Mo, Cr, V, W, Se and Zr on properties, selection of materials for definite purposes, the various types of SAE steels, and fields of application for each type are dealt with. Ha (D-4a)

The Manufacture of Seamless Steel Pipe in the Plants of the National Tube Company. EDWIN C. WRIGHT & STEVENSON FINDLATER (Natl. Tube Co.) *J. Iron Steel Inst.,* Advance Copy No. 17, Oct. 1938, 15 pp. Description. A short history of the company is given, with particular reference to the growth of the seamless tube process that now represents 60% of the company's production. JLG (D-4a)

The Production of Flakes by Treating Molten Steel with Hydrogen and the Time of Cooling Necessary to Prevent their Formation. R. E. CRAMER & E. C. BAST (Univ. Illinois) *Am. Soc. Metals,* Preprint No. 14, 1938, 15 pp. Research to determine effect of H content and cooling rates after rolling on flake formation. A number of ½ x 3 in. bars from six 5-ton ingots (C 0.66-0.77 Mn 0.63-0.87%), 3 of which were treated with H in the mold during solidification, were sectioned at the hot saws and cooled at controlled rates through various temperature ranges by packing in insulated boxes. Control specimens were cooled on the mill floor. Specimens were macroetched in 50% HCl to reveal flakes. Flakes were found to be more numerous in the control specimens from H-treated ingots. The time required in slow cooling between 900° and 200° F. to eliminate flakes varied from 3 hrs., 20 min. to 9 hrs., 11 min., depending on the tendency of the steel to develop flakes. Flakes developed in most of the bars below 300° F. The results of these experiments are not meant to apply to bars of other compositions and dimensions. A survey of recent literature on flakes in steel is presented. Many investigators are associating the development of flakes with the presence of H in steel. See also Metals and Alloys, Vol. 9, Apr. 1938,, p. MA 240 R/6. HLW (D-4a)

Relations between Hydrogen and Flakes in Steel. KANJI MATSUYAMA, KIYOSHI SASAKAWA & TSUNEYO IKI. *Tetsu-to-Hagane,* Vol. 24, Mar. 25, 1938, pp. 234-247. In Japanese. Research. Ni-Cr and other structural and stainless steels were heated at 1150° C. in a current of H_2 or air for 6 hrs. and quenched in water, then tempered at 820° and 650° C. for 1 and 4 hrs., respectively. Further, H_2 or N_2 was introduced into the steel melt before pouring. The presence of flakes was investigated micro- and macro-scopically. Flakes appear in steel containing H_2, but are caused not only by H_2 but by thermal and transformation stresses. Chemical composition of steel also has an effect on the formation of flakes. TS (D-4a)

Machinability of Steels, Ratings Based on Relative Speed of Removing Metal. J. SORENSON & W. GATES. *Product Eng.,* Vol. 10, Jan. 1939, pp. 12-14. Practical. Combination tables and charts are given for some 100 standard steels giving ultimate strength, elastic limit, elongation, reduction of area, hardness, machinability rating and machining time index. The application of the data to the calculation of shop cost for machining is explained. Ha (G-4a)

4b. Non-Ferrous

Machining of Magnesium Alloys; Reaming-Milling-Sawing-Tapping-Broaching-Filing-Grinding-Cooling and Lubrication (Spangebende Formung von Magnesiumlegierungen; Reiben-Fräsen-Sägen-Gewindeschneiden-Räumen-Feilen-Schleifen-Kühlung und Schmierung) E. RAUSCHER. *Maschinenbau Betrieb,* Vol. 17, Dec. 1938, pp. 613-615. Practical. Spiral-teeth tools must be used for reaming, and if teeth are straight, there should be an odd number of them. Reamers may be used that are ground as are tube bits. All milling operations can be easily applied to Mg alloys. For wide, long surfaces, cutter heads of light metal bodies are used; the cutting edges are either high-speed steel or sintered carbide. Face mills must have large gaps well rounded off at the bottom. For finger mills, the same rules apply as for spiral drills. Disc mills as well as circular saws must be ground thinner toward the center. Slight crossing is used for large thin saws as well as for hand saws. Special formation of teeth is recommended. Threads produced by taps or dies should be made with special tools, if possible, the tool to be designed so as to reduce friction. Automatic-opening die heads should be used on turret lathes and automatic screw machines. Small taps have 2, larger ones 3 cutting edges. Broaches should be provided with chipping angles. The clearings are chosen so as to avoid sticking. Rough cut is used for files that are best made by milling with inclined or sector-shaped cut. Grinding is usually done wet. Crude petroleum or very dilute soda solution is used as cooling medium. After grinding, the pieces must be dried and covered with acid-free oil or petroleum so as to prevent staining. When ground dry, dust has to be sucked away. Mg alloys are usually machined dry. If a lubricant is used (on screw machines), it should have a high ignition point. A special cooling liquid has been developed that acts as a fire extinguisher in case of ignition. Compressed air is frequently used for cooling and chip removing; a condensate trap must be provided in the line. RPS (G-4b)

Some Experiments in the Grain Refinement of Duralumin. I. IGARASHI. *Nippon Kinzoku Gakkai-Si,* Vol. 2, Sept. 1938, pp. 466-475. In Japanese. Original research. The tensile strength and endurance limit of duralumin decrease as the grain size increases. Fine grained structure is therefore very important, and may be obtained by one of the following methods: (1) Keep the percentage of cold extension less than 2 or greater than 10. (2) Increase the percentage of reduction, and lower the temperature of forging. (3) Increase the percentage of Mn up to 1.2. NS (D-4b)

5·HEAT TREATMENT AND HEATING

Aging, Annealing, Carburizing, Hardening, Malleableizing, Nitriding, Normalizing, Surface-Hardening and Tempering. Furnaces, Soaking Pits, Refractories, Atmospheres, Fuels and Auxiliaries.

O. E. HARDER, SECTION EDITOR

Design of Specialized Fuel Fired Furnaces. J. L. RUNDLE. *Heat Treating Forging,* Vol. 24, Oct. 1938, pp. 522-526; Nov. 1938, pp. 575-577. Discusses principles. Considers burners and combustion chambers; temperatures, temperature distribution, and pressures in combustion chamber; heat transfer to working chamber; temperature distribution in working chamber; flue ports; and indirect heating. Very high rate of heat liberation is ordinarily of no advantage. The combustion chamber should be too large rather than too small, and combustion should be complete before the gases leave the chamber. Temperature of the combustion chamber may be determined (or better, estimated) from a knowledge of fuel conditions (heat input) and the various heat loss factors: wall conduction, port hole radiation, and convection by furnace gases. Efficient, even temperature distribution in the combustion chamber is favored by greater chamber width. Small ports aid in attaining even (high) gas velocity through the ports, but they also reduce the direct radiation area to the work chamber. The designer has considerable latitude in selecting size, number and shape of ports, and can usually achieve an excellent balance of opposing factors. Many diagrams are used to illustrate heat flow paths and rates, pressure and velocity distribution, etc. MS + FPP (5)

Electric Resistance Furnaces. A. J. G. SMITH. *Electrical Rev.,* Vol. 123, Dec. 9, 1938, p. 824. Descriptive. A vertical pit-type furnace has been developed that can be used for all heat-treating processes involving temperatures up to 950° C. There are 2 separate systems of heating elements. For temperatures up to 650° C., the furnace works in conjunction with a heating shaft at side of working chamber. The shaft is provided with a series of withdrawable heating elements at the top and a forced circulation fan at the bottom for circulating the heated air with great velocity through the charge in the working chamber via top and bottom flues. For high temperatures, communication with the shaft is shut off by dampers of special heat-resisting steel in the flues, and the furnace operates as an independent unit in the normal way without air circulation. The cover for the working chamber is hydraulically operated. MS (5)

Controlled Heat Dissipation. J. G. COUTANT. *Iron Age,* Vol. 142, Oct. 13, 1938, pp. 247-248, 252-254. Practical description of advances made in construction of annealing furnaces using light weight refractories capable of controlling rate of heat dissipation. Pit type annealing furnaces for chilled car wheels are considered and data on the calculations used in the design of these furnaces given. VSP (5)

Electrode Salt Baths. *Wild-Barfield Heat Treatment J.,* Vol. 3, Dec. 1938, pp. 31-33. Descriptive of a new electric salt bath furnace designed especially for hardening high speed steel. The furnace is 3-phase, and employs 3 electrodes 120° apart around the bath periphery. Heat is generated by the passage of current through the salt; current passage also produces a stirring action in the molten salt. The bath lining is of specially selected bricks, with recesses to accommodate the electrodes. In operation, a set of small auxiliary electrodes is inserted to "start" the melting of the solid salt, more and more of which is added until the auxiliary electrodes can be withdrawn and the main electrodes used. The furnace is circular and is covered with an easily-removable hood and fume-removal system. These are made easily removable because the corrosive nature of the hot salt necessitates replacement of lining and electrodes after the bath has been in use "for some time". Complete description of electrical control, temperature indicating system, etc. are given. FPP (5a)

Automatic Charging Devices for Salt Bath Furnaces (Selbsttätige Beschickungsvorrichtungen für Salzbadöfen) W. UNTERKIRCHER. *Durferrit Mitt.,* Vol. 7, Oct. 1938, pp. 51-67. Practical. Mechanical transportation of parts to be hardened through preheater, salt baths, quenching and cleaning tanks is especially recommended for heat treating oil hardening steels and carburized case hardening steels. Fully automatic charging devices are suggested when large amounts of similar pieces are to be heat treated; semi-automatic devices should be applied with small turnover or with difficult quenching procedure. A device, fully automatic, is described for the treatment of oil hardening and carburized case hardening steels, distinguished by many safety features. When space is lacking, a revolving apparatus is recommended. The furnaces are arranged in a circle. Charging devices of simple construction for manual quenching are also considered. GN (5a)

Cyaniding of High Speed Steel. D. A. PROKOSHKIN & V. S. TSAREGORODETS. *Metallurg,* Vol. 13, July/Aug. 1938, pp. 28-39. In Russian. Research. Steel samples containing 0.74% C, 4.02% Cr, 18.4% W and 1.27% V were first heated in salt baths to 800°-850° C. in 12-15 min. and then to 1280°-1300° C., and kept at that temperature for 2-3 min. The samples were then held for 40 min. in a muffle furnace at 550°-560° C. and cooled in still air to room temperature. After polishing, they were subjected to cyaniding in baths of 90% NaCN, 47% KCN+53% NaCN, 90% $K_4Fe(CN)_6$ + 10% KOH, at 560°-570°, 560°-570°, and 550°-560° C. respectively. During the first 15 min. the hardness rises considerably, but longer periods produce a more gradual increase. The C in the steel became concentrated on the surface and formed a cementing layer, but the N diffused deeper in the Fe. BZK (5a)

The Electrical Surface Hardening of Machine Parts. I. V. BURGSDORF & M. B. MAKOGON. *Metallurg,* Vol. 13, July/Aug. 1938, pp. 9-21. In Russian. Practical. Satisfactory results were obtained in the surface hardening of machine parts using the Vologdin (high frequency current) method. The hardened layer was 3.0-3.5 mm. deep, and the hardness was 60 Rockwell C. At a depth of 3 mm. the hardness was 54 Rockwell C. The layer showed even gradation from surface to unhardened core. The structure was fine-grained with no traces of overheating; the martensite needles were very small. At 1.75 mm. small troostite grains appeared, at 2.5 mm. ferrite made its appearance, and at 3.25-3.5 mm. there was an abundance of small-grained ferrite and troostite. The distortion of parts did not exceed that produced by other methods of surface hardening. BZK (5a)

The Heats of Formation of Various Nitrides. *Shun-ichi Satoh. Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Oct. 1938, pp. 1356-1361. In English. Original research. Not only the properties of the elements themselves, but the properties of their corresponding compounds are also frequently periodic. Thus, the heats of formation of nitrides of the elements are tabulated in a "periodic chart" and graphically presented by plotting atomic number against heat of formation. Periodic curves are obtained that permit rough prediction of the heats of formation of nitrides hitherto unknown, such as:

$$\tfrac{1}{2}\,(N_2) + [As] = [AsN] - 33.9 \text{ k. cal.}$$
$$\tfrac{1}{2}\,(N_2) + [Sc] = [ScN] + 75.0 \text{ k. cal.}$$
$$\tfrac{1}{2}\,(N_2) + [Hf] = [HfN] + 78.3 \text{ k. cal.}$$

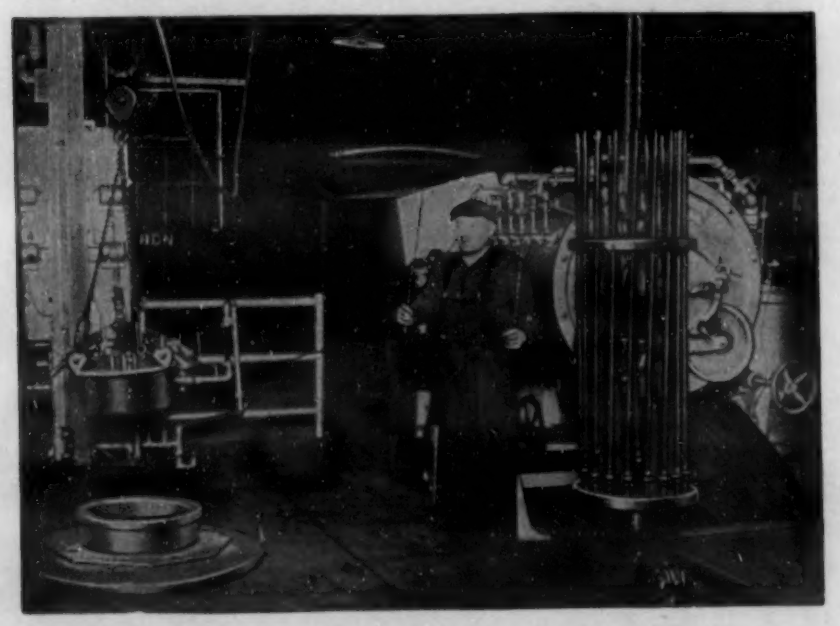
For previous work, see also *Metals and Alloys,* Vol. 9, Nov. 1938, p. MA 673 R/7. EF (5a)

The Effect of Sulphur Gases upon Scale Formation during Heat Treatment. B. A. MOROZOV & A. V. TURSUNOV. *Metallurg,* Vol. 13, July/Aug. 1938, pp. 22-27. In Russian. Practical. Presence of about 0.025% S gases in the combustion products (oxidizing atmosphere) at 800°-860° C. resulted in a sharp increase of scaling in steel of 1.0% Cr and 4.0% Ni. When the S gases reach 0.05-0.1%, the metal surface becomes strongly saturated with S. The scaling proceeded in the form of a strongly corroded uneven layer. This loss is considerably reduced in a neutral atmosphere and is totally absent in a reducing atmosphere. High S fuel may be used in an oxidizing atmosphere provided the combustion products are diluted with air to contain less than 0.025% S gases. BZK (5a)

NEED SPECIAL SHAPES FAST?

Cast them yourself with

J-M FIRECRETE



...and you'll save time, labor and expense

THIS dependable, hydraulic-setting refractory can be used to make any shape right in your own plant. Ready-mixed and easily cast, it handles like ordinary concrete. Ideal for poured door linings, flues and pipes, for dampers. And Firecrete is strong and durable, will not shrink, crack or disintegrate. You'll want full details on this and other dependable J-M Refractories. Write Johns-Manville, 22 East 40th Street, New York City.

1 **Effect of Primary Austenite Grain Size on the Properties of Steel.** IWAN FESZCZENKO-CZOPIWSKI & BOLESLAW STEGENTA. *Hutnik,* Vol. 10, No. 11, 1938, pp. 559-573. In Polish. A discussion of the effect of "primary" austenite grain size as determined by carburization or a similar method points out that preliminary heat treatment largely removes the differences between the mechanical properties of coarse and fine-grained steels, but does not change the nature of the primary austenite grains. Heat treatment of steel with fine primary austenite produces, as a result of allotropic change, a finer secondary grain than that obtained in the case of the same steel with coarse primary austenite grain size. Extensive hot plastic treatment decomposes the primary austenite grains to some extent, the decomposition sometimes beginning within the grain. The grain size at a fracture after hardening depends not only on the primary austenite grain size, but also on the form of cementite before hardening. Primary austenite grain size can be only qualitatively estimated by comparison of fractures of samples hardened at different temperatures the method of normalizing at 925°-980° C. (Przeglad Techniczny, No. 18, 1936, pp. 550-552) was found to be most suitable for rapid microscopical determination of approximate grain size. The McQuaid-Ehn method, or its modification, as suggested by the writer (heating for 4 hrs. at 900°), give better results. 15 references. JGT (5a)

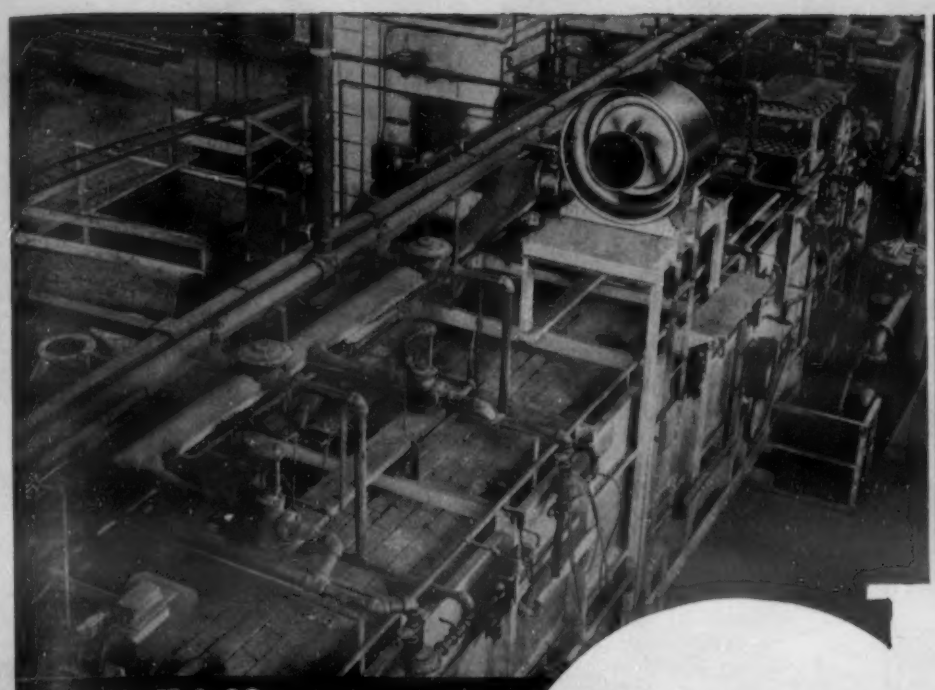
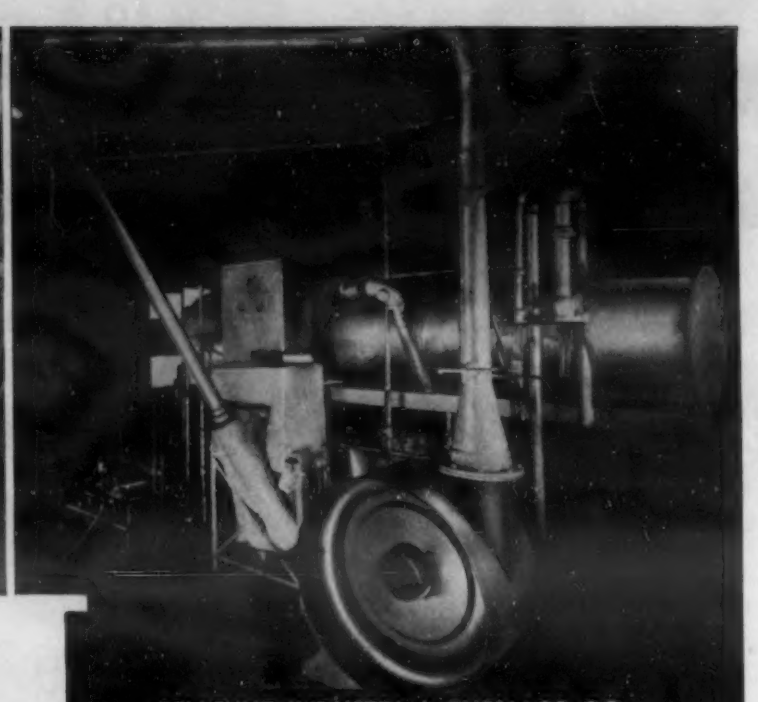
4 **Electric Heat Treating of Seamless Chromium-molybdenum Tubes.** F. VDOVIN. *Stal,* Vol. 8, May 1938, pp. 48-54. In Russian. Original research. Steel tubes 20 mm. in diameter with a wall thickness of 0.75 mm., containing 0.30% C, 0.22% Mo, 0.85% Cr, 0.55% Mn, 0.27% Si, 0.022% S and 0.015% P, were heated to 800°-950° C. by passage of an a.c. of 450, 680 or 800 amps. and allowed to cool in air. Heating required approximately 360, 80 and 30 sec., respectively. A sorbitic microstructure with the best mechanical properties was obtained by heating to 880°-920° C. Tests made on tubes of various sizes gave the same results, except that the largest tubes tested, 65 mm. in diameter by 1.5 mm. thickness, required heating to 1000° C. All tubes heated to their proper temperature range in 1 min. satisfied and, in most cases, considerably exceeded the specifications for tensile strength (100,000 lbs./in.^{2}) and elongation (11%). HWR (5a)

5 **The Change of Mechanical Properties and Microstructure of Gray Cast Iron due to Heat Treatment.** TAKETO YOKOYAMA & HIROSHI KISHIMOTO. *Tetsu-to-Hagane,* Vol. 24, Apr. 25, 1938, pp. 321-326. In Japanese. Gray cast Fe (3.16% T.C., 2.30% graphite, 1.12% Si, 0.43% Mn, 0.63% P) whose tensile strength and Brinell hardness were 31,000 lbs./in.^{2} and 240, respectively, were subjected to various heat treatments, *viz.* quenching at 750°-1050° C. in oil, water and salt-bath and tempering at 150°-300° C. The specimen quenched at 800° C. and tempered at 250° C. showed the highest tensile strength, *viz.* 43,000 lbs./in.^{2} The highest Brinell hardness (550) was obtained from the sample quenched at 800°-850° C. Change in microstructure was the same as in the case of steel, except, of course, for the graphite. The specimen quenched at 800°-850° C. and tempered at 150°-200° C. showed the highest resistance to 10% HCl solution. TS (5a)



6

7 **American Soaking-pit and Reheating-furnace Practice.** FREDERICK M. GILLIES & EDWIN D. MARTIN. *J. Iron Steel Inst.,* Advance Copy No. 8, Oct. 1938, 30 pp. Up-to-date review. A detailed description of the various types of soaking pits and reheating furnaces used at different American plants. Regenerators and recuperators used with the furnaces are also discussed. Poor quality of heating takes a heavy toll from forging and rolling operations; American industry came only gradually to recognize this and to spend, as it has since 1934, $15,000,000 on new fuels, regenerators, recuperators, control systems, refractories and heat resisting alloys, and on new furnace designs. In 1937 alone 150 new soaking pit installations were made in America. Four distinct types of soaking pits are discussed, and statistics are given that offer a cross-section of present American equipment and practice. JLG (5a)



8

9 **Quenching into Hot Salt** (Härten im Warmbad) R. VOEGELIN. *Durferrit Mitt.,* Vol. 7, Oct. 1938, pp. 68-79. Practical. The theoretical principles underlying the quenching of steel into hot salt, are outlined, and the advantages of this heat treating method are discussed. Potassium nitrate bearing salt baths proved most successful; a mixture melting at 140° C. is generally applied. Hot salt quenching in general is only applicable to alloy steels, such as Cr-Ni, Cr-Ni-Mo and Cr-Mo carburizing steels and all kinds of tool steels commonly oil hardened. Recently, however, hot-hardenable low-alloy steels have been developed. If small quantities are to be quenched, the common types of quenching furnaces are satisfactory. If large quantities require treatment, air cooling is too slow. Internally heated electric salt bath furnaces are recommended, such as those of Kärcher, in which the bath tank is water cooled outside. Such water cooling proved many times more effective than air cooling. GN (5a)

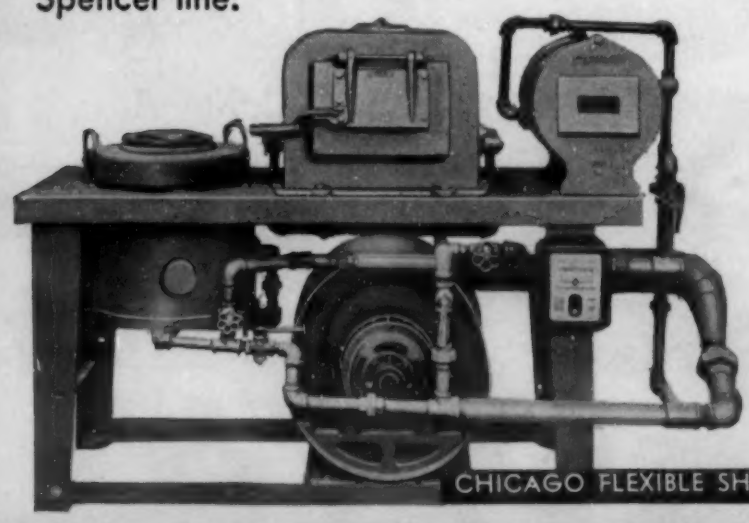
BELLEVUE INDUSTRIAL FURNACE CO.

SPENCER TURBOS AT WORK

SALEM ENGINEERING COMPANY



STANDARD FUEL ENGINEERING CO.

"They provide a steady flow without pulsation and are comparatively free of noise as well as maintenance expense," writes one manufacturer who has used Spencer Turbos for more than 20 years. Another manufacturer says, "We like them because we can put them in and forget them." Others comment on conservative ratings, the low cost, and good engineering and sales help obtained from Spencer.

This universal acceptance can be summed up in one word—dependability.

When you need air service, ask your furnace manufacturer about Spencer Turbos, or write for the Spencer Turbo Bulletin and the Spencer Data Book. Visit plants where Spencer Turbos have been in use for a quarter century and remember that every year has seen marked improvements and extension to the Spencer line."

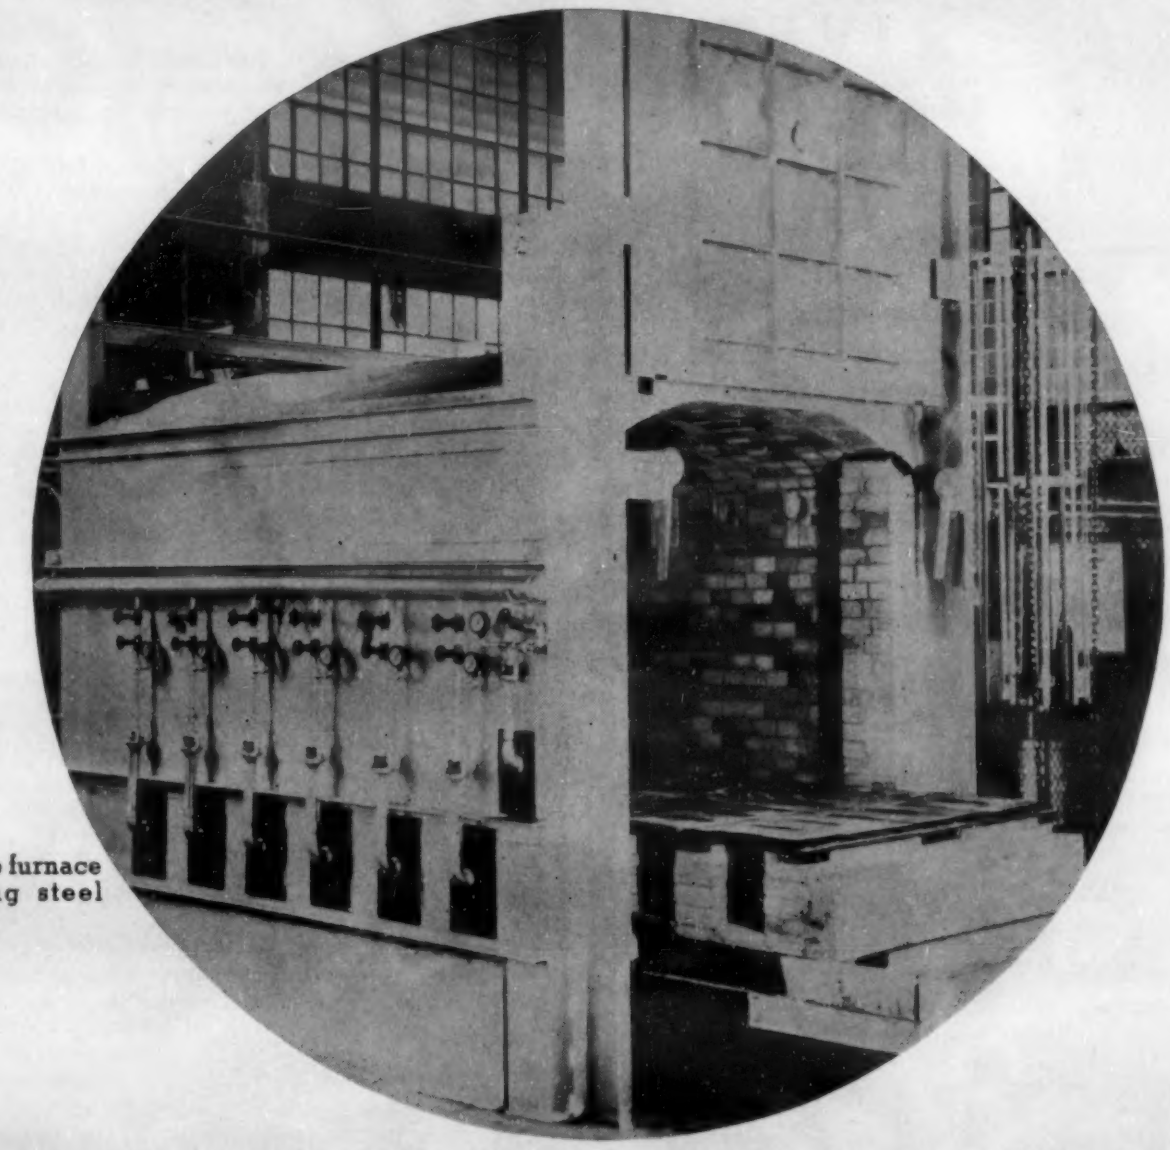
Hardness Factors. WM. CONLEY & DONALD E. RODA. *Steel*, Vol. 103, Dec. 12, 1938, pp. 56-58. Original research, showing that most uniform results in hardening strip steel parts are obtained when size of quenched section is in agreement with C and Mn content. Steels used contained (1) 0.38% C and 0.68% Mn, (2) 0.58% C and 0.66% Mn, and (3) 0.58% C and 0.78% Mn. "The microscope showed that the austenitic grain size was same for these 3 steels" is the only "information" on grain size given. Sections were built up of ½ in. by 0.04 in. tensile test-pieces. They were held at a hardening temperature of 1480° F. for 5 min. and quenched in oil, at room temperature, or in salt bath at 625° F. After hardness readings were made, oil-quenched steels were drawn at 625° F. for ½ hr.; in the constant temperature transformation, the parts remained in the hot salt 15 min. Hardness readings were again taken along center of tensile section and 1-in. grip section and across test-piece. Tensile tests were then made. Variation of C content between steels 1 and 2 caused maximum hardness variation of 12 points Rockwell C in a section 0.08 in. thick. Variation of Mn content between steels 2 and 3 produced maximum hardness variation of 30 points Rockwell C in a section 0.12 in. thick. When width of quenched part was increased to 1 in., Mn in steel 3 was able to maintain hardness in spite of greater mass. Drawing greatly reduced the variations in hardness found in the hardened state. Results of tensile tests indicated that strength bears a close relation to hardness. Every point change in Rockwell hardness resulted in about 4,500 lbs./in.^{2} difference in maximum strength. In no case did a tensile test-piece fail through a section containing a Rockwell indentation. Readings across test-piece, instead of lengthwise, showed only a few points variation in hardness. Hot salt quench gave more uniform results than oil quenching and drawing. For all sections over 2 pieces of the hot salt-quenched samples, strength values were higher for the surface than the center pieces. For 3-piece section, hardness increased from one steel to the other by very uniform steps not shown in the oil-quenched and drawn tests. MS (5a)



Plain Carbon-tool Steels, Their Heat Treatment and Applications (Unlegierte Werkzeugstahle, ihre Warmebehandlung und Anwendungsmöglichkeiten) ERICH EICHWALD. *Automobiltech. Z.*, Vol. 41, Dec. 25, 1938, pp. 634-638. Useful data compilation. Plain C-tool steels usually develop a glass-hard surface zone around a tough core when quenched in water from a suitable hardening temperature; they may be more sensitive to checking (thin sections, sudden change in cross-section) than the usual oil hardening steels. With up to 1.7% C they can be forged, rolled and machined with or without previous annealing. With up to 0.6% C they are malleable and can be pressure-welded. A useful table contains steels of various German manufacturers, their treatments and application. The steels should be heated slowly for forging and cooled moderately slowly, *e.g.* in dry ashes. Forging temperatures vary widely for different brands between 750° and 1100° C. Annealing is accomplished between 650° and 770° C. For hardening, straight quenching in water of 20° C. is usually applied. Sometimes the steel is dipped into water and then into oil, or vice versa. Other quenching media are suggested for a few steels. Hardening from the forging heat is not permissible. Hardening temperatures are closely confined and vary between 740 and 870° C. Plain C tool steels should be tempered immediately after hardening to relieve hardening strains, avoid brittleness and maintain toughness of the core. Tempering temperatures above 320° C. are not used. The correct steel is selected mostly according to the stress on the tool, or its ability to hold cutting edge, or its resistance to wear. The type of machining operation, the material to be machined and its temperature are criteria. The required hardness, sensitivity to overheating, size and shape of the tool also influence selection of a tool steel. RPS (5a)

New Furnace Broadens Use of "Moly" Tools. *Iron Age*, Vol. 142, Dec. 22, 1938, pp. 30-31. Practical description of a new gas-fired heat treating furnace introduced by Surface Combustion Corp. It is claimed to be the first atmospheric furnace that will satisfactorily heat treat Mo tool steels without "soft skinning" or "surface decarburization." The equipment is known as the Char-Mo furnace. The furnace is not restricted to heat treatment of Mo steels, but at heat treating temperatures its atmosphere is non-decarburizing and non-oxidizing for all steels except those of high Cr content. Results of Application of Streamlined Form of Bricks in Regenerators of Steel Mill Furnaces. ROMAN DAWIDOWSKI. *Hutnik*, Vol. 10, No. 10, 1938, pp. 507-515. In Polish. Results are given of an inspection of a regenerator in which the checker work is made up of bricks of a newly developed streamlined shape. A saving of 24.5% fuel with an increase in the life span of the brickwork, permitting a corresponding rise of the amount of steel produced per ton checker work from 110.2 to 203.2 tons, is made possible by this innovation. 15 references. JGT (5a)

Gas HEAT TREATING FURNACE

PERMITS A TEMPERATURE RANGE OF 1500°

GAS-fired car type furnace for heat treating steel castings.

Temperatures required for the heat treating of steel castings in the car type furnace shown above range from 350 degrees to 1850 degrees. Because it permits a greater range of turn down than other fuels, this furnace is fired with GAS.

Quality of the castings is maintained at a high peak by automatically controlled heat, good combustion and improved furnace atmosphere conditions obtained by the use of GAS. In this furnace such features resulted in efficient annealing and tempering of castings, but they are advantages which will step up efficiency and bring greater economy to the operation of any plant where heat must be applied to metals.

Learn how GAS can solve the production problems that involve heat in your plant. It may turn present losses into future profits.

Impact Torsion Tests of Quenched and Tempered Tool Steels. M. ITIHARA. *Nippon Kinzoku Gakkai-Si,* Vol. 2, Nov. 1938, pp. 552-557. In Japanese. Original research. Impact torsion tests of 3 plain C tool steels were made with a tester having capacity of 30 kg.-m. with initial striking speed of 1,000 rev./min. Two maxima occurred in the C steels that were tempered at 200° C. and 350° C., and 2 minima at 270° C. and 400° C. For these steels, tempering up to the first maximum point is most desirable for tools. NS (5a)

M. H. MAWHINNEY, SECTION EDITOR

The Development of Age-hardening Alloys I. *Light Metals,* Vol. 1, Dec. 1938, pp. 395-400. Comprehensive review. The relationship between constitution and age-hardening is reviewed. Phenomena included in this conception are the usual decreasing solid-solubility with fall in temperature in a terminal solid solution, eutectoidal decomposition, phase changes with falling temperature in intermediate phases, and superstructure. In the case of Mg alloys, for example, age hardening results have been thus far somewhat disappointing. The best age-hardening effects are usually obtained when the separating phase is not a pure metal or terminal solid solution, but a β phase or hard intermetallic compound, as $CuAl_2$ in Al-rich Al-Cu alloys. The temperature level at which age-hardening is produced is also of prime importance in determining the amount of hardening. This may explain the failure of most elements which when added to Pb, for example, fail to produce hardening even when the type of constitution is favorable. Failure for age-hardening to occur when it is expected may be due to other causes than unavoidable over-aging. For example, it is not always possible to retain a solid solution stable at high temperatures by rapid cooling (quenching). In other cases, the alloy approaches equilibrium so slowly that at reasonable aging temperatures, no hardening occurs. Eutectoid transformations cannot always be undercooled, and the quenched alloy may be exceedingly hard. Alloys not exactly of eutectoid composition usually suffer composition changes when cooled from the single phase region to the eutectoid temperature. These composition changes may form the basis of age-hardening. Very frequently the decomposed eutectoid is made up of one or two hard intermediate phases, and if this is the case, the resulting alloy is usually stable and is able to retain its hardness. A valuable addition to this review is a complete list of terminal solid solutions of binary alloys that show decreasing solid solubility with fall in temperature together with age-hardening data, where such exist. AUS (5b)

The Development of Age Hardening Alloys. II. *Light Metals,* Vol. 2, Jan. 1939, pp. 17-22. Comprehensive review. Peritectoid alloys may be hardenable owing to the difference in position of a 2-phase alloy with respect to the 2 bounding solid solutions, above and below the transformation temperature. Order-disorder alloys may be hardenable if the ordered "phase" has a different crystallographic structure in terms of unit cell and symmetry than the original "phase." For example, in the case of AuCu, a tetragonal structure is formed in the ordered, or semi-ordered phase, and the alloy is thus hardened; the $AuCu_3$ superlattice is distinguishable from the unordered lattice solely by the relative positions of the Au and Cu atoms, and no hardening occurs. The hardening of alloys of the AuCu type depends upon undercooling the alloy into an unstable state where ordering proceeds by standing at some suitable low temperature. The heat treatment is entirely analogous to the case of precipitation hardening. Similarly, also, the aging temperature must not be too high, since the end-point of practically complete order may result in a hardness lower than the highest possible hardness. The maximum hardness is usually attained at some intermediate point between complete order and complete disorder. Additions of third or even fourth elements to alloys capable of forming suitable superlattices may result in increased hardness. An example is the addition of Ag to AuCu. As is well known, many of the important age-hardenable alloys of commerce are ternary or even more complex alloys. Two such examples are duraluminum (Al-Cu-Mg) and tempaloy (Cu-Ni-Si). Many ternary age hardenable alloys may be considered as pseudo-binary alloys, such as $Cu\text{-}Ni_2Si$ (tempaloy) mentioned above. Most of these alloys are of the simple precipitation type where the α solid solution has a broader solid solubility range at elevated temperatures than at lower temperatures. On the other hand, age hardening is not necessarily confined to alloys that are homogeneous solid solutions at elevated temperatures; but duplex alloys can often separate a third constituent at lower temperatures, and hence give rise to age hardening. Certain alloys, such as N-bearing Fe and Al-Mg alloys are suitably hardened by merely cooling from the casting temperature, and are not improved by solution quenching. In most cases of precipitation hardening in an unstable solid solution, maximum

THE TWO-COMPONENT CASE-HARDENING BATH

Balanced for Controlled Results!

THE two-component bath provides rapid and uniform hardening. Its activity, and the metallurgical results are under your control at all times. This bath is the result of extensive research, and has been tested and proven under the most extreme operating conditions to be found in practice.

In the two-component bath, a low-cost bath material is used to fill the pot and to replace drag-out losses, while an activating agent is added in small amounts at predetermined regular intervals, to maintain the activity of the bath at a constant level.

Easy control of the bath composition is thus provided at all times, which naturally results in production of a metallurgically uniform case. In addition, the bath is noncorrosive, provides rapid penetration, has low volatility and is extremely fluid at all operating temperatures.

Cyanamid offers two pairs of case-hardening compounds with which you can attain the obvious advantages of the two-component bath—*AEROCASE #28 & #510 for maximum economy in large-scale hardening, and *AEROCARB A & B for greatest efficiency where easy washing is desired.

With either material, excellent case characteristics and unusually rapid penetration are obtained uniformly and efficiently at all times, and operating costs are extremely low. Your inquiries are invited on this method, and at your request we will indicate whether AEROCASE or AEROCARB best suits your needs.

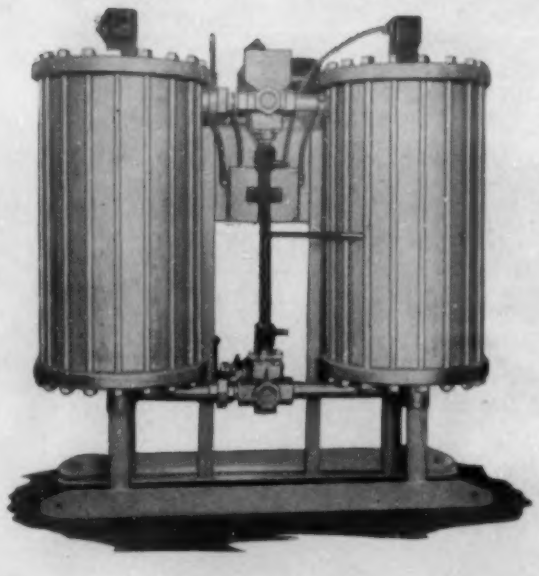
WE'RE LOOKING for TOUGH TEMPERATURE CONTROL PROBLEMS

The "Alnor" Electronic Pyrometer Controller has been adapted to many special and unusual applications. For instance, one "Alnor" now in use is equipped with a double target, arranged to progressively close two valves. A secondary source of heat supply is first shut off, leaving the main source to take care of normal heat requirements. This is an ideal arrangement for maintaining extremely close temperatures under intermittent loads, and effectively prevents "hunting" and "overshooting."



Write!

We would like to show you how we can solve *your* control problem . . . at surprisingly low cost. Write your requirements, and let us give you a recommendation and price.

hardness is usually attained in alloys whose composition lies near or at the solubility limit at the solution-treating temperature; but there are cases where maximum hardness is attained in alloys whose composition lies well within the solid solution field, such as Al-$MgZn_2$, or in the duplex field, an example of which is Cu-rich Cu-Ag. Pb-Sb is an example of an age-hardening system where the addition of small amounts of other elements greatly improves age-hardenability. The pure binary alloy exhibits very little age-hardenability, but the presence of .005% Cu and .05% As allows the hardness to increase from 4.9 to 13 Brinell. Third elements may be added for other reasons than increasing the hardenability. For example, Mn is added to duralumin for improvement of the corrosion resistance. The solution treating temperature should be as low as possible to avoid excessive grain growth. The best temperature for the aging treatment is usually a compromise between that dictated by experimental results and that dictated by economic considerations. Age hardening may be made to proceed more rapidly at higher temperatures, but the maximum hardness is usually reached by relatively long aging times at lower temperatures. Another factor to be considered is possible loss of ductility or corrosion resistance, which is apt to accompany an alloy in the fully-aged or over-aged condition. In development work it is important that the results of various aging times at various aging temperatures be known; otherwise the behavior of the alloy in comparison to other alloys may be very misleading. While hardness and tensile strength are the 2 properties that are most frequently plotted as a function of the changes occurring in an alloy during age hardening, other properties may be important in some applications. Age hardening rarely improves the fatigue strength. Cu-Be is an exception to this, but the accompanying loss in damping capacity is often a detriment to its use in some instances. In the general field of non-ferrous age hardening alloys, some unique attribute or group of properties is necessary to place a new alloy in the field. The development of new alloys in the future will, in general, be concerned with those which exhibit definite superiority over existing alloys for use in some unique or clearly defined application.

Some New Solutions for the Heat Treatment of Light Metals in Electric Furnaces (Einige neue Lösungen bei der Wärmebehandlung von Leichtmetallen in Elektroöfen) OTTO GENGENBACH. *Vorträge der Hauptversammlung 1938 der Deutschen Gesellschaft für Metallkunde, V.D.I. Verlag, Berlin,* 1938, pp. 94-96. Original research. Describes and illustrates 9 recently developed German electrical furnaces for heat treatment of light metals. Efficiency of heat transfer by radiation is much smaller than by convection. The heating units are sometimes arranged in a special chamber and the furnace atmosphere always circulated by fans. With the increasing use and size of light metal structures and parts, larger furnaces as described in the paper have been constructed. The trend towards automatic (hydraulic) charging and discharging is apparent. Light metal sheets are subject to warping on quenching in water. An annealing furnace is shown that is directly connected with a "quenching chamber" that can be quickly filled with spray. By using spray or cold air blast warping is avoided.

EF (5b)

The Recrystallization and Softening of Wrought Magnesium Alloys (Ueber die Rekristallisation und Entfestigung der Magnesium-Knetlegierungen) W. BUNGARDT, K. BUNGARDT & E. SCHIEDT. *Metallwirtschaft,* Vol. 17, Dec. 2, 1938, pp. 1267-1272. Research. Recrystallization study of 2 commercial Mg sheet alloys, one (Mg-Al 6) containing 6.40% Al, 0.29% Mn and 0.90% Zn and the other (Mg-Mn) containing 2.02% Mn. Metallographic, X-ray and physical property studies were carried out on alloys cold rolled various amounts and annealed at various temperatures for 30 min. The recrystallization of the Mg-Al 6 alloy cold rolled 6-17% and annealed for 30 min. takes place over a temperature range of 60°-70° C. and is complete at 310° C. The recrystallization temperature range for the Mg-Mn alloy is 220°-290° C. for alloys cold rolled 8-57%. Recrystallization is complete in this alloy at temperatures of from 420° to 450° C. Physical property tests for the Mg-Al 6 alloy cold rolled 3.2, 5.5 and 10% and for the Mg-Mn alloy cold rolled 3.9, 5.6 and 11.2% confirm the X-ray studies.

GA (5b)

Annealing Brittleness of Si-bronzes. S. KURODA. *Nippon Kinozku Gakkai-Si,* Vol. 2, Dec. 1938, pp. 619-628. In Japanese. Original research. Si-"bronzes" (Cu-Zn-Si alloys) develop certain peculiarities on annealing at 300°-500° C.; shock resistance and elongation decrease, hardness increases, and yet tensile strength remains almost the same. Within the above temperature range, the higher the temperature and longer the time of annealing, the more brittle the alloy becomes. This is attributed to precipitation of γ phase in the grain boundaries of α phase by decreasing solubility of Si in the α phase. Attempts to prevent this precipitation by addition of other elements gave little success. The solubility of Si at 250° C. in Cu-Zn alloys was much less than that given in former reports.

THE WAY TO MAKE *Light Work* OF YOUR REFRACTORY PROBLEMS!

You can experiment if you wish, or you can eliminate the guesswork by using P. B. SILLIMANITE. It's as pure as it is humanly possible to make it, and solves your refractory problems with a satisfaction far beyond that of any ordinary refractory.

Imported in the raw state solely by us from India, refined by an electro-magnetic separator that removes the iron, dirt and other fluxing impurities, subjected to our own process of manufacturing and development, it wins the preference because it gives you a more consistent, longer refractory life.

Whether it be P. B. SILLIMANITE Air-Setting Cement, Ramming Mix, Patch (Wet or Dry), or Hydrocast, you can be confident it is the best that money can buy.

If the results you are getting are not entirely satisfactory, try P. B. SILLIMANITE as produced by The Charles Taylor Sons Company, and you'll be a consistent user from that time forward.

If your problem is different, it will be to your advantage to tell it to our Engineering Department. Do it today.

6·WELDING AND CUTTING

Including Brazing, Hardfacing, Riveting and Soldering. For Flame-Hardening, see Section 5.

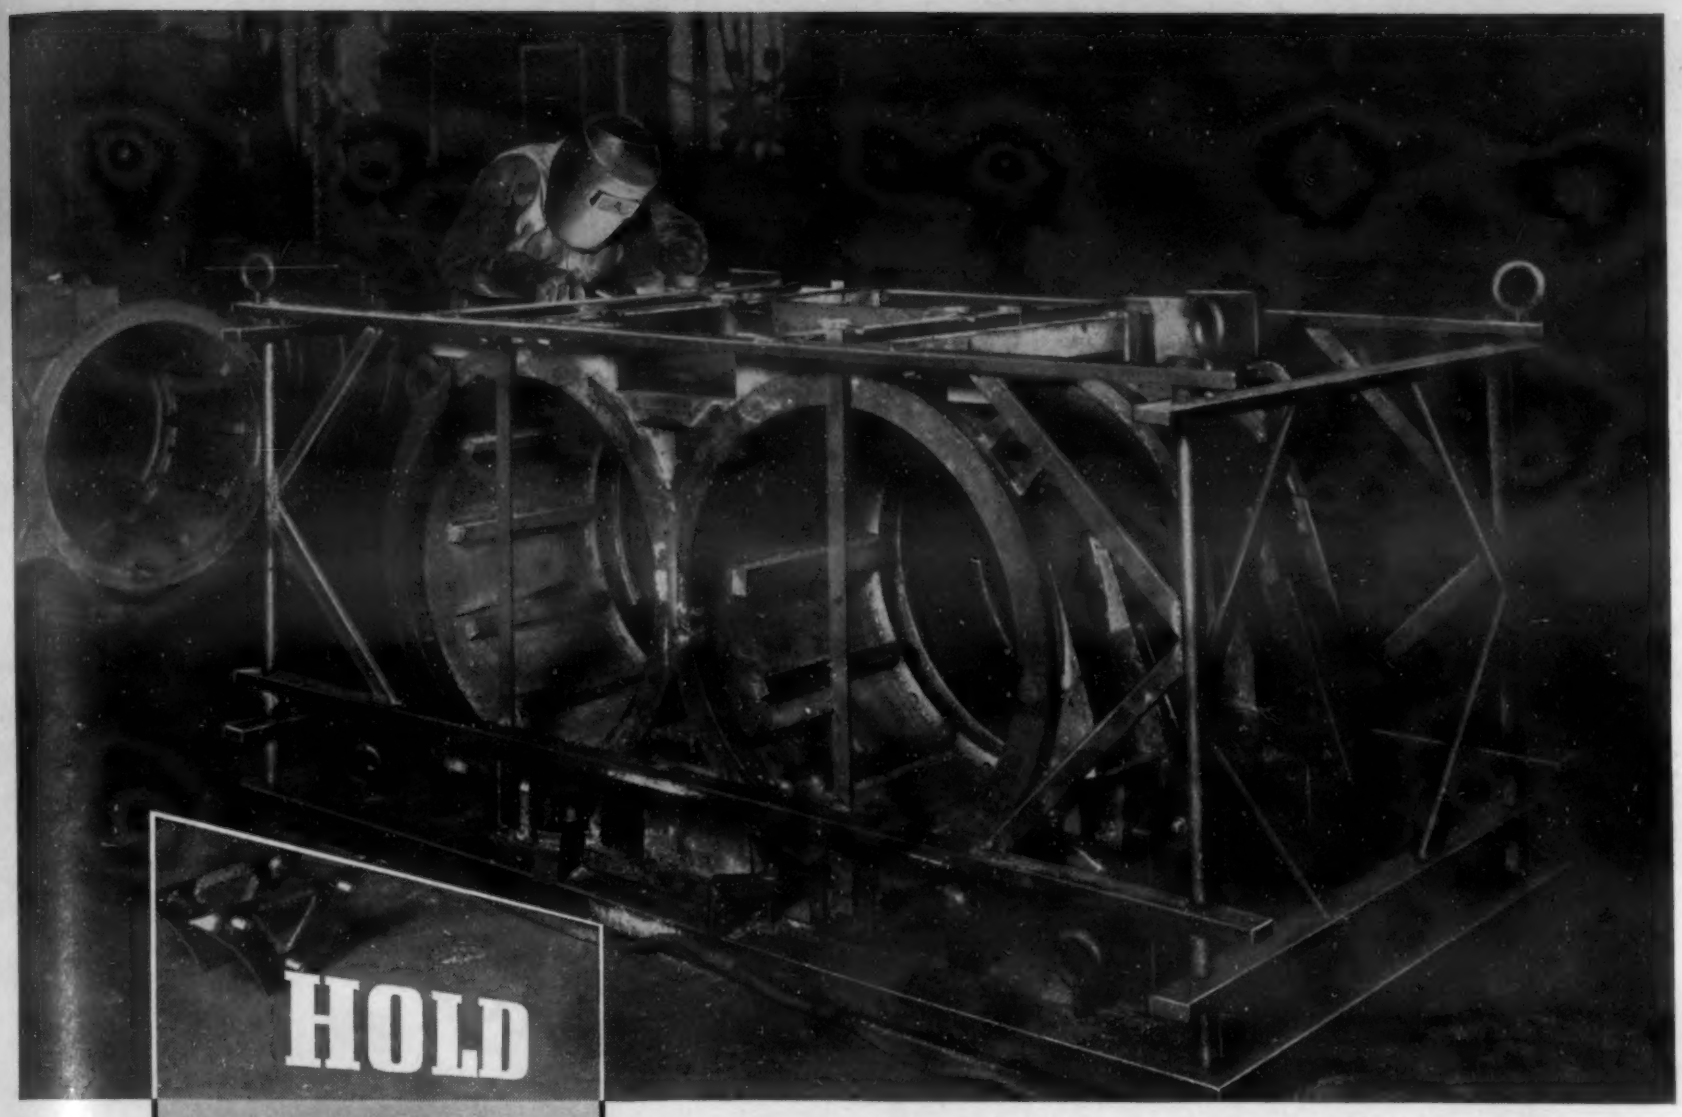
E. V. DAVID, SECTION EDITOR

Shrinkage Control. G. J. GIBSON (Pittsburgh-Des Moines Steel Co.) *Steel*, Vol. 103, Dec. 5, 1938, pp. 56-57. Practical. Recommendations are given for avoiding or diminishing shrinkage due to welding. Although they apply particularly to butt joints, the same principles pertain to fillet welds. Smallest amount of weld-metal possible and smallest groove permitting desired penetration should be used. Practical limits for field welding are 60° vee with a 3/32-1/8 in. root spacing for complete penetration. Electrodes should be used that require least heat per unit of weld deposited within the limits that produce acceptable weld-metal. High welding currents, large electrode diameter or electrode with high melting speed and small spatter loss will produce most deposited weld-metal per unit time. Never permit piece being welded to cool for a long period unless weld is built up to full plate thickness. Use a partly fixed condition, such as weights on tack welding. Distribute heat over length of long seams by starting at center and welding toward each end, using step-back method. Wherever possible protect parts during or after welding, until they are at room temperature. Weld plates in such thick layers that reverse side assumes a red heat during welding, and use a means of restriction against bending. In general, weld all end connections of plates first and then long seams between. Where transverse joints occur, weld them first and then weld shapes to plate using intermittent fillet welds where possible. Joints causing greatest shrinkage should be welded first, and joints causing least shrinkage welded last. Cold peening is particularly effective in reducing shrinkage stresses when plates are restrained. In unrestrained plates, hot peening immediately after welding is easier and just as effective. Each layer should be peened over its entire surface using rapid, light blows. Blunt-nose peening tool is best. Transverse shrinkage of lap joints is not as important as that of butt joints. Longitudinal shrinkage along joint is much less troublesome. It appears to be a constant of about 0.035% over seam length for butt, lap, and tee joints in plates 3/16-1/2 in. thick. Intermittent welds will produce less shrinkage than continuous welds. Curves showing amount of transverse shrinkage for various types of butt-welded joints and various plate thicknesses, and relative shrinkage of different types of joints are presented. MS (6)

6a. Ferrous

Manufacture and Properties of Thin-walled Welded Pipes of Steels of High Strength (Herstellung und Eigenschaften nahtgeschweisster Rohre aus Stählen höherer Festigkeit) H. CORNELIUS. *Autogene Metallbearbeit.*, Vol. 31, Nov. 15, 1938, pp. 361-364. Descriptive. Tubes of 1 mm. wall thickness can be made of Cr-Mo and Mn steels with welded seams with as satisfactory mechanical properties as seamless tube if, after the oxy-acetylene welding, the seam is annealed so that recrystallization in the weld takes place and the whole pipe is soft-annealed before cold-drawing, to 6-8% greater width. Defective welds develop cracks under such treatment, so that they are rejected in an early stage of the manufacture. Ha (6a)

Using Ni-clad Steel. Part I. F. P. HUSTON (Internatl. Nickel Co. Inc.) & T. T. WATSON (Lukens Steel Co.) *Welding Engr.*, Vol. 23, Dec. 1938, pp. 19-21. Practical. Strength of the Ni-to-steel bond was demonstrated by means of a specially prepared bar so designed that the break at ultimate tensile strength occurred in the steel weld at 50,900 lbs./in.^{2} Material may be gas-cut almost as readily and at about the same speed as steel plate. Joints may be made by welding, the Ni side being welded with Ni welding rod. Corrosion resistance is entirely adequate for the purposes that employ Ni-clad steels. Metallic arc method is generally used. CEJ (6a)



The Fatigue Strength of Oxyacetylene Welded Rails. OTTO GRAF. *Welding J., N. Y.*, Vol. 17, Nov. 1938, Suppl. pp. 29-30. Extended abstract of article in *Autogene Metallbearbeit.* See *Metals and Alloys*, Vol. 10, Jan. 1939, p. MA 47L/5. CEJ (6a)

Low-alloy Welding Steels. HOWARD STARK. *Ind. & Welding*, Vol. 2, Dec. 1938, pp. 44-45. Review. The physical properties of low-alloy high tensile steels are considerably better than those of mild steel, and yet do not materially affect the forming operations. Practically all the steel manufacturers are producing some form of these new materials, and the various analyses that are being marketed are as varied as the makers. Some are dependent upon small additions of Cr for the increased strength, others upon Mn, Si, Ni, Cu, and combinations of these. Welding electrodes of comparable analyses can be secured for use with any of these new steels, and many of these materials have better welding characteristics than either flange or firebox steel. It can be only a matter of time until industry will use the low alloy steels to a very great extent. CEJ (6a)

6b. Non-Ferrous

Progress in Copper Welding. I. T. HOOK & C. E. SWIFT (Am. Brass Co.) *Welding J. N. Y.*, Vol. 17, Oct. 1938, Suppl. pp. 48-60. A report of a research survey of weldability of known alloys and welding rods under conditions of welding similar to service. A brief historical review of evolution of Cu welding is made, and a detailed account is given of the research program for evaluating (a) relative melting point, (b) strength, (c) ductility, (d) soundness, (e) flowing properties and (f) general properties (color match, grain size, hardness, corrosion resistance and fatigue resistance). Tabulated results are given for all the welds tested, made by the oxyacetylene and C-arc method. General conclusions are: (1) In any method of welding, better weld strength and ductility are obtained in deoxidized Cu base metal than in tough-pitch or electrolytic Cu base metal. This is true whether the base metal is deoxidized with P or with Si. (2) The Si-deoxidized Cu base metal shows better hot ductility than the P-deoxidized Cu. (3) In the welding rod for gas welding, the P should be low, of the order of 0.03%, while in an arc-welding rod, 0.08% is insufficient. On the other hand, 0.25% P makes a satisfactory arc-welding rod. If Si is used as the deoxidizer or strengthening agent in the welding rod, 0.06% is too low for arc welding and is also slightly low for insuring soundness in gas welding. (4) With either gas or arc welding, the M rod having 3% Si, 1% Mn and the remainder Cu, shows close to the maximum results in both strength and ductility. The L rod, high in both Sn and P, gives results as good as those of the M rod in arc welds, but is unsatisfactory for gas welds. (5) In general, the arc welds show a higher strength in electrolytic Cu base metal than do the gas welds. By and large, the gas welds can be depended upon for an efficiency of only 60%, while the arc welds should develop 80%. (6) The P-containing rods should be melted with a long arc, while the Si-containing rods are preferably melted with a short arc. (7) The P-containing rods can be applied only in the flat or nearly flat position, while the Si-containing rods can be used to a limited degree in position welding. WB (6b)

Welding of Non-ferrous Metals with Butane-oxygen (Schweissen von Nichteisenmetallen mit Butan-Sauerstoff) V. THÜRNAU. *Autogene Metallbearbeit.*, Vol. 31, Nov. 15, 1938, pp. 364-367. Descriptive. Non-ferrous metals, except hydronalium, can be successfully welded with a mixture of butane and O. The width of the weld is less for butane than for acetylene, so that the wire consumption is lower, but although butane is cheaper than acetylene, oxyacetylene welding is cheaper as the welding speed for the latter is higher. No neutral flame exists for butane as for acetylene. The low flame temperature makes the oxybutane flame unsuitable for welding of Fe sheets. The flame will be used with advantage only in such cases where (as in welding of foils) city gas or H had previously been used. Experiments with different metals are described in detail, as well as the arrangement of burners and mixtures. Ha (6b)

HOLD THE COSTS *with* PAGE Hi-Tensile "F"

● A good welder working with Page Hi-Tensile **"F"** electrodes makes the perfect combination for holding welding costs to low levels.

Page Hi-Tensile **"F"** is fast and smooth running. It is excellent for horizontal, vertical and overhead jobs—and for working in close quarters. It produces welds of great strength and high ductility. Spatter and slag losses are exceptionally low. Hi-Tensile **"F"** is especially adapted to work on Cro-Man-Sil, Cor-Ten, H.T.-50 and other new alloy steels.

See your local Page distributor for full information on Hi-Tensile **"F"** and other Page electrodes.

7·FINISHING

Pickling, Cleaning, Sandblasting and Polishing. Electroplating, Metallizing, Galvanizing and Tinning. Coloring, 'Oxidizing' and Non-Metallic Finishing.

H. S. RAWDON, SECTION EDITOR

The Development of Metal Coating Technique in 1937 as Reviewed in the German Patent Literature (Die Entwicklung der Metallüberzugstechnik im Jahre 1927 an Hand der deutschen Patentliteratur) K. NISCHK. *Oberflächentech,* Vol. 15, Dec. 6, 1938, pp. 233-236; Dec. 20, 1938, pp. 247-249. German patents for cleaning, degreasing, polishing, pickling of metals, electroplating, and protective films by anodic treatment, and for hot-dipping in molten metals are reviewed, and some applications described in detail. A pure Au layer on a Au alloy is, according to DRP 644,602, produced not by electrodeposition or hot-gilding, but by anodic treatment for 2-3 min. in a solution of 2% HNO_3; the alloying constituents are removed from the surface metal, and the piece is then rinsed in distilled water and polished. Ha (7)

7a. Electrolytic Methods

Control of Plating Solutions. *Electrical Rev.,* Vol. 123, Oct. 21, 1938, pp. 575-577. Practical. Describes methods of and equipment for filtration, agitation, heating and testing. Continuous filtration is necessary for agitated solutions, particularly warm Ni-plating solutions. Agitating and filtering apparatus are now combined in new installations. Filter unit consists of vitreous enameled filter pots carrying 7 or 10 filter "candles" made of kieselguhr. Candles are mounted on a plate or grid that can be easily withdrawn. Air-circulating pump and a motor-driven air-valve are used. Another type is a self-contained motor-driven portable unit, in which filter pots, motor, pump, and suction and delivery hose are mounted on a trolley for placing alongside vat. This is used in conjunction with a storage vat that is mounted on a raised platform. Efficient method for average-size warm Ni-plating plant is a cone-type filter unit mounted at opposite corners of plating tank, with agitation effected by rotary air-pump taking air from a container and discharging it from jets through coils in bottom of tank. Heating coils are placed alongside. For automatic plants, filter pots with kieselguhr candles or special filter-presses may be used. In both cases, solid Ni motor-driven pumps and storage tanks are employed. Most common form of electric heating is a cable laid on floor of tank. This is suitable for warm Ni, acid Cu, Zn and all acid plating solutions. For Cr baths, electric ring units are used. Cyanide and alkaline solutions are heated by an immersion heater. Acidity of Ni solution can be measured by means of comparators of colored glass or paper. Salt-spray method is the most reliable for testing corrosion resistance of plated articles. Paper coated with ferroxyl indicator affords a quick test for porosity in small plants. Test sets are available for controlling free cyanide in Cu, Ag, Au, Cd and brass solutions; free acid in acid Cu solutions; free KOH in Sn baths; metallic content of Cd solutions; and thickness of Cd deposit. Free KCN in a $Cu(Cn)_2$ bath should be maintained at about 1½ oz./gal. Good free cyanide for a hot brass solution is 1½-1¾ oz./gal. and for a cold solution, 2¼-2½ oz./gal. MS (7a)

Rochelle Salt Cyanide Copper Baths. R. M. WAGNER & M. M. BECKWITH. *Proc. Am. Electroplaters' Soc.,* June 1938, pp. 147-163. Original research. The effect of variation of bath composition and operating conditions on cathode and anode current efficiency was studied. The determination of free cyanide by $AgNO_3$ titration was found to be influenced by the conditions of titration. A high CuCN concentration in the bath is favorable as it increases anode and cathode efficiency. The NaOH concentration should be 0.05-0.5 oz./gal.; if higher, anode efficiency decreases, although cathode efficiency is not affected. Free NaCN should be about 0.75 oz./gal.; higher concentrations do not materially increase anode efficiency but considerably decrease the cathode efficiency. The Rochelle salt concentration does not appreciably affect the cathode efficiency; 2-4 oz./gal. is the best for optimum anode corrosion. The Na_2CO_3 content should be low, about 2 oz./gal. Higher amounts decrease anode and cathode efficiencies. Carbonate can be decreased by adding tartaric acid, which liberates CO_2. Anode and cathode efficiencies decrease with increase of current density. Both increase with the temperature, but there is little gain above 150° F., and the loss of cyanide is greater. Fe in the bath reduces anode efficiency and should not exceed 0.75 g./l. As little as 0.1 g./l. of Cr as chromate will stop deposition. AB (7a)

Wetting Agents in Nickel Plating Solutions. NEWARK BRANCH OF THE A. E. S. *Proc. Am. Electroplaters' Soc.,* June 1938, pp. 225-235. Practical. Wetting agents are added to prevent pitting of deposits by H bubbles. The wetting agents are sodium alkyl sulphates, alkyl naphthalene sulphonates, fatty acid amides, etc. They prevent pitting by lowering the surface tension of the liquid so that gas bubbles can not cling to the plated surface and are more economical than H_2O_2 for stopping pitting as they do not rapidly decompose. Wetting agents should be soluble; if they precipitate, they produce poor Ni deposits. Their concentration is maintained in accordance with surface tension measurements. Surface tension at first decreases with increasing concentration of wetting agent but, after a certain concentration is reached, becomes constant. Addition of agent beyond this concentration is uneconomical and may also cause pitting. The surface tension of a solution should be below 37 dynes/cm. to prevent pitting. Oil, soap and foreign matter must be kept out of the tanks as they will be emulsified by the agent and produce inferior Ni deposits. Wetting agents can be removed from a bath with $KMnO_4$, followed by an increase in the pH, then by a treatment with activated clay and activated C, and filtering. AB (7a)

A Study of Cyanide Copper Plating Baths. C. B. F. YOUNG & GERALD REID. *Metal Ind., N. Y.,* Vol. 36, Dec. 1938, pp. 560-562. Effects of variations in pH, temperature, current density and concentration in copper cyanide solutions were studied. The following formula is recommended: CuCN 12 oz./gal., NaCN 14 oz./gal., Na_2CO_3 10.5 oz./gal., temperature 70° F., current density up to 20 amps./ft.², anode efficiency 75%, cathode efficiency 91% and pH 11 (determined by paper strip). 60	12.81	12.80	18.30	15.92	18.7

With quick immersion, increase of Al content results in lower attack; with long immersions, increase of Al results in increased attack. Micrographs are included. Ha (7b)

The Application of Polishing and Buffing Wheels. ROBERT T. KENT. *Metal Cleaning Finishing,* Vol. 10, Nov. 1938, pp. 762-775. Descriptive. A discussion of automatic and semi-automatic polishing and buffing machines. Hand lathes for heavy duty should have an arbor 1.5 in. or more in diameter. Variable speed is desirable, so that the correct surface speed can be obtained with buffs of different sizes. There are 3 types of automatic or semi-automatic machines: (1) Straight-line machines; (2) multiple-head machines; (3) contour machines. Their general principles of design are discussed. The straight-line machine consists of a series of wheels that float on the work with a predetermined pressure, the work being carried under the wheels on a conveyor chain. Small pieces are loaded on a work fixture that may be locked onto the conveyor while the latter is in motion. The multiple-head machine consists of a head that carries a number of chucks for holding the work. The head in rotating brings each piece of work into contact with a wheel for a predetermined time. The chuck may rotate and bring all sides of the object into contact with the wheel. Several wheels can be used so that cutting down and coloring can be done at the same time. Contour machines are used to finish work of non-circular cross-section. The work is rotated and at the same time kept in contact with the wheel by a cam arrangement. AB (7b)

Wear Resistance. W. H. SPENCER (Sealed Power Corp.) *Steel,* Vol. 103, Dec. 5, 1938, pp. 60-62. Industrial note. Describes the "Granosealing" process for phosphate treatment of Fe and steel wearing surfaces to prevent scuffing. The surface to be treated is put into a cleaning solution at 140° F. and rinsed in H_2O at same temperature. Ordinary Fe and steel parts are then placed in a treatment bath. Hardened steel or chilled Fe are preferably etched in acid before being treated. Bath consists of dilute H_3PO_4 containing Mn and saturated with Fe. Careful control of concentration of the solution is not important. Treatment period (indicated by cessation of gas evolution) ranges 5-30 min., depending on composition of metal, and strength and temperature of solution. For piston-rings, solution contains about 2% free acid, the temperature is 210° F., and immersion time is about 10 min. Parts are then washed in 140° F. H_2O and dipped into a soluble oil solution. Thickness of coating can be varied by changing methods of application. Minimum thickness ordinarily used is about 0.00025 in. The surface retains oil and rubs down, to produce a polish with a metallic appearing finish. The treatment is not claimed to prevent scoring due to faulty cooling of engine or to distortion of cylinder; it does, however, prevent scuffing in new engines during wearing-in period. Where scuffing conditions are not present, it reduces amount of wear. MS (7b)

Corrosion Protection of Aluminum-magnesium Alloys by Cladding (Korrosionschutz von Aluminium-Magnesium Legierungen durch Plattieren) P. BRENNER. *Metallwirtschaft,* Vol. 17, Dec. 2, 1938, pp. 1272-1276. Original research. Investigation of cladding as a means of combatting intercrystalline corrosion in Al-Mg alloys containing considerable Mg (7-8%). If pure Al is used as a protective covering, severe attack will take place at the unprotected regions. High Mg alloys were successfully protected with an Al alloy coating containing 5% Mg. This latter alloy is not susceptible to intercrystalline corrosion. Cladding with an alloy of lower Mg content alloy reduces the potential between core and cover plate and lessens corrosion at cut edges. The same effect can be obtained by cladding with a thin Al layer and then diffusing Mg out of the core by annealing. Al-Mg clad material containing about 1% Zn assists materially in reducing corrosion, with the retention of tensile strength. GA (7b)

Welding of Magnesium Alloys (Schweissen von Magnesiumlegierungen) P. BRÄUER & O. LEHMANN. *Autogene Metallbearbeit.,* Vol. 31, Dec. 15, 1938, pp. 398-401. Practical. The proper procedures for welding Mg alloys, whether rolled, forged, cast or die-cast, are discussed at length. All Mg alloys can be satisfactorily welded if the proper flux is employed, which dissolves the oxide layer protecting the metal and prevents the burning of the edges; several commercial types are described. The welding rod should always be of the same material as the basis metal. The torches used for Al can also be used for Mg welding, but with a slight excess of acetylene. The spots to be welded must be well cleaned; castings should be heated after welding to 350° C., slowly cooled in the furnace, and the flux residue washed off with warm water. If, despite all care, a piece should start to burn, sand and gray Fe scrap should be used for extinction—but no water. Many examples are given. Ha (7b)

Hints on Silvering Glass. F. E. J. OCKENDEN. *J. Sci. Instruments,* Vol. 15, June 1938, pp. 206-208. Detailed description of the silvering of glass with the well known Edel formula, comprising silver nitrate and potassium sodium tartrate. Soap is recommended for cleaning, since caustic soda or strong alkalies may result in fogging. Oxidation of the deposit is prevented by using special care in mixing and boiling to remove dissolved O. A bluish white fog indicates tap water contamination. RAW (7b)

Saves Metal and Acid

RODINE

is cutting costs in 95 per cent of the country's pickling rooms.

RODINE

more than pays for itself. By its use, economies of 30 to 60 cents per ton of metal pickled are frequently gained.

RODINE

eliminates pitting of the metal. Minimizes acid brittleness. Reduces rusting of pickled stock.

RODINE

makes pickling operation easily controlled and gives consistent results.

Radiography and X-ray Crystallography in Industry. F. BRECH (Adam Hilger) *Light Metals,* Vol. 2, Jan. 1939, pp. 27-30. Review. X-ray diffraction is gradually assuming its place in modern metallurgical industry for testing metallurgical products and processes. Some problems that may be solved by its use are as follows: (1) Determination of crystal structure; (2) identification and analysis of phases present in an alloy; (3) examination for the presence of surface deposits, scale and other surface phenomena, and of the physical and chemical properties of such deposits; (4) determination of grain size; (5) determination of the effects of changes of crystal grain orientation produced by rolling, drawing and extrusion; (6) detection of effects due to hot and cold work; (7) detection and analysis of regular and irregular strains on either side of the yield point; (8) investigations of strain release resulting from heat treatment; (9) chemical analysis. The use of the X-ray diffraction method in the problems listed above is briefly described, and several typical photograms are shown that clearly illustrate the effect of cold work, heat treatment, etc. on the diffraction lines. [While this paper describes no new methods or techniques, and hence is more or less wasted on the technically trained metallurgist, it should be required reading for executives who pass on purchases of equipment and who have not yet heard of the industrial possibilities of X-ray diffraction. A.U.S.] AUS (R-8)

Graphic Determinations of the Characteristic Bend Curve of Constant Cross Section Shapes in the Elastic-plastic Region (Zeichnerische Ermittlung der Biege-Kennliniebeliebiger Querschnittsformen im federnd-bildsamen Bereich) ST. SZTATECSNY. *Metallwirthschaft,* Vol. 17, Oct. 21, 1938, pp. 1101-1104. Theory and comparison with experimental results. The formula $M_1 = \Theta_a . E . W$ describes the bend curve in the elastic region. M_1 is the bending moment, Θ_a the elongation in the outermost fibers, E the modulus of elasticity and W the section modulus of the whole cross section. Another formula $\frac{M_2}{M_s} = 1/W . [W^1 + F'' . Z_s]$ is derived to describe bending of a section of constant cross section in the elastic plastic range. M_2 is the bending moment at any time in the elastic plastic range, M_s the bending moment corresponding to yielding in the outermost fibers, W the section modulus of the whole cross section (W^1 the section modulus of the elastically deformed cross section), F'' the area of the plastically deformed cross section, and Z_s the distance between the neutral axis and the center of gravity of the elastically deformed region. A graphic method for determining this curve for shapes difficult to calculate is set up. The theoretically derived curve coincides well with actual data from bend tests. GA (T-8)

Examination of Welds by Magnetic Testing Methods (Untersuchung von Schweissnähten mittels der magnetischen Werkstoffprüfung) J. STAEBLER. *Autogene Metallbearbeit.,* Vol. 31, Dec. 15, 1938, pp. 393-398. Deviations in the normal magnetic arrangement of Fe filings give a more sensitive test for defects in magnetic materials than even X- or γ-ray methods. Principles of methods and apparatus, and their application, are described in detail, and illustrated by examples. Instead of dry Fe filings, so-called metal oil is now generally applied, which permits the Fe filings to arrange themselves much easier in the magnetic lines. The oil consists of a suspension of finest Fe powder (gray carbonyl Fe powder or black Fe_3O_4) in a suitable oil. Ha (R-8)

An Apparatus for the Direct Indication of Damping Capacity (Ein Gerat zur unmittelbaren Dämpfungsanzeige) F. FÖRSTER & H. BREITFELD. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 343-345. Experimental. A self-exciting vacuum tube circuit is described by means of which damping capacities can be determined at 4-sec. intervals. Applications of this equipment during stress and recovery of an Al rod, during the cooling of a stressed steel rod, and during the accelerated elongation of an Al rod are described briefly. GD (T-8)

The Present Status of Spectrographic Analysis, Especially that of Metals (Der heutige Stand der Spektralanalyse, insonderkeit von metallischen Proben) WALTER GERLACH. *Metallwirtschaft,* Vol. 17, Nov. 18, 1938, pp. 1217-1222. Review. A general survey of the methods and applications, especially as practised in Germany, of qualitative and quantitative spectrochemical analysis of metals and alloys is given. For general qualitative analysis, the author's interrupted arc spectral source is recommended. Two recent modifications of this source, developed by Van Calker (see *Metals and Alloys,* Vol. 9, June 1938, p. MA 372 R/7) and by Pfeilstricker, are described. The possibility of analysis for P, S and the halogens is discussed. For the quantitative analysis of metallic alloys, the use of the Feussner condensed spark and of microphotometric measurements of spectral line blackenings, as described in numerous previous publications, are recommended. A good description is given of the well-known pre-spark effect and of its possible causes. J. S. Owens (H-8)

The Effect of the Speed of Stretching and the Rate of Loading on the Wielding of Mild Steel. E. A. DAVIS (Westinghouse Elec. & Mfg. Co.) *J. Applied Mechanics, A.S.M.E.,* Vol. 5, Dec. 1938, pp. A137-A140. Research. The behavior of mild steel during the first stages of yielding is influenced by stress concentration and speed of deformation. Local yielding produces a condition equivalent to stress concentration at the boundary of the yielded portion which, in turn, causes a rapid strain rate that allows the load to drop in an ordinary testing machine. The conditions under which upper and lower yield points appear are investigated thoroughly; the lower yield point is the load at which the strain rate produced by the high stress developed due to local yielding becomes equal to the strain rate prescribed by the testing machine. 12 references. 8a. Fatigue Testing

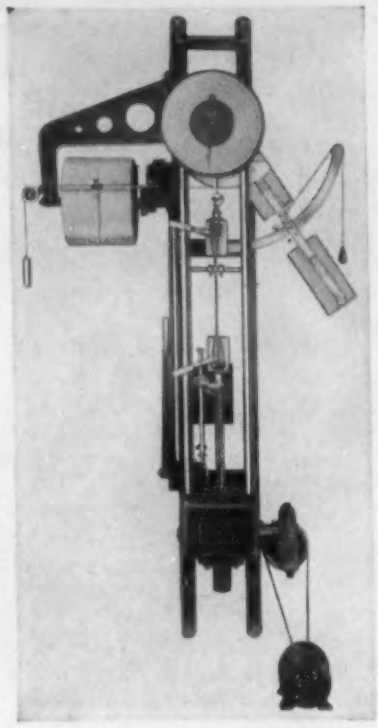
H. F. MOORE, SECTION EDITOR

The abstracts appearing under this heading are prepared in cooperation with the A.S.T.M. Research Committee on Fatigue of Metals. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

Experiments to Increase the Torsion-fatigue Resistance of Shafts with Transverse Holes by Means of Cold Working (Versuche zer Steigerung der Verdrehdauerhaltbarkeit quergebohrter Wellen durch Kaltverformung) A. THUM & H. WEISS. *Automobiltech. Z.,* Vol. 41, Dec. 25, 1938, pp. 629-633. Original research. The materials used for specimens were Cr-Ni-W-steel and Cr-Ni-Mo-V-steel, both hard or tempered. The specimens were of 60 mm. diameter; with a 5 mm. transverse hole. The change in cross section by holes is taken into account when computing stress, but not the deformation by cold working. Endurance was determined by Wöhler's method with an ultimate number of 10×10^6 cycles. In preparing the specimens, the same changes in shape as effected by cold working were reproduced by machining to indicate what changes in results were actually due to cold work rather than merely change in shape. Experiments with flat punches used to press the shaft in the neighborhood of the transverse hole showed that an increase in endurance could be obtained. Cracks occurred at a stress below the fatigue limit of the untreated material, leading to failure only at higher stresses. The effect of the cold deformation does not relax, as determined by a test with 100×10^6 cycles. The cracks started at an angle of 45° to the axis. At the point where the edge of the punch had acted they stopped and, when the stress was increased, continued at 90° to the first direction. The fracture frequently occurred close to the boring, its location depending upon the pressure applied. The maximum endurance was found at a cold-working pressure that

caused the fracture to start at the edge of the hole itself. If the pressure is increased further, the endurance drops and may fall below the value of untreated specimens. According to the crack phenomena observed, a special punch shape was developed that presses the material in the direction of 45° to the axis and avoids overstressing in the other directions. With this tool the cold working of the hole-edges increased the fatigue strength markedly. Pressures of 28-30 tons were applied. The material is pressed up into pads around the boring. The fatigue resistance was increased when turning the specimens down to the original diameter. Very little scatter of the test result is noted, which indicates that the notch-effect is counteracted in a proper manner. By proper cold-deformation of the boring edge the fatigue resistance could be increased 28-63%. In all cases a fatigue limit of 80% of that of plain specimens could be obtained with the bored shafts. RPS (8a)

The Effect of Permanent and Intermittent Acting Oscillating Over Loads on the Development of the Fatigue Fracture (Der Einfluss dauernd und unterbrochen wirkender, schwingender Überbeanspruchung auf die Entwicklung des Dauerbruchs) HELMUT MÜLLER-STOCK. *Mitt. Kohle u. Eisenforsch,* Vol. 2, No. 2, 1938, pp. 83-107. Original research. In studying the effect of alternating peak stresses on the fatigue limit, it is important to study the development of a fatigue fracture with uniformly oscillating load. The experiments were carried out on a Schenck endurance bending machine with a rotating sample of St. 37 with 0.06% C, 0.01% Si, 0.50% Mn, 0.025% P, 0.025% S and 0.09% Cu. The fatigue limit was 31,000 lbs./in.^{2} Upon loading a test specimen above its fatigue limit, a temporary improvement of material is first observed, *i.e.* when a sample is preloaded for a short time, and then subsequently subjected to a certain higher relative load, it sustains a higher number of oscillations till fracture than when only tested with the higher load. When the preload lasts a long time, the number of oscillations endured decreases upon second loading. The change of this duration is represented by an S-shaped damage curve. The material improvement first observed is followed by a steep ascent of damage. Shortly before fracture, the damage increases less rapidly. The retardation of the damage occurrence could not be explained. The more the oscillating load increases, the more the damage curve approaches the straight line supposed for the relatively higher load. Simultaneously, the number of oscillations during which a transitory material improvement is observed decreases. The fatigue limit of a material impaired by pre-allied oscillations does not decrease in a straight course with increasing damage, but does so relatively slowly at first, and rapidly later. However, a material impaired by overloads still possesses a fatigue limit, provided the damage was not too large. Experiments with oscillating loads alternating above and below fatigue limit gave the same type of results as when tested only above the fatigue limit. A few tests on structural steel St. 52 and a Si-Mn spring steel proved the results on St. 37 also to hold true in principle for these steels. 14 references. [These results are in harmony with those obtained by Kommers, see *Metals and Alloys,* Vol. 9, No. 10, Oct. 1938, p. MA 616 R/3.—H. F. M.] GN (8a)



Simultaneous Effects of Corrosion and Abrupt Changes in Section on the Fatigue Strength of Steel. T. J. DOLAN (Univ. Ill.) *J. Applied Mechanics, ASME,* Vol. 5, Dec. 1938, pp. A141-A148. Original research. Experiments were made to determine whether the weakening effects of a stress raiser and of corrosion during repeated stress are additive. Fatigue tests in reversed flexure and in reversed torsion were carried out on SAE 3140 steel hot-rolled, quenched and tempered. The following results were obtained:

Treatment	Type of stress	Stress raiser	Endurance limit, lbs. per sq. in.		Stress concentration factor	
			In Air	In stream of water	Due to stress raiser	Due to stress raiser + corrosion
Hot-rolled	Reversed torsion	None	44,000	32,500	1.00	1.35
		Fillet	28,000	30,000	1.57	1.47*
		Hole	22,000	13,500	2.00	3.26
	Reversed flexure	None	64,000	34,000	1.00	1.88
		Fillet	36,000	19,000	1.78	3.37
		Hole	31,000	16,000	2.06	4.00
Quench and temper	Reversed torsion	None	56,000	32,500	1.00	1.72
		Hole	30,000	20,000	1.87	2.80
	Reversed flexure	None	90,000	13,000	1.00	6.92
		Fillet	36,000	11,000	2.50	8.18
		Hole	31,000	9,000	2.90	10.00

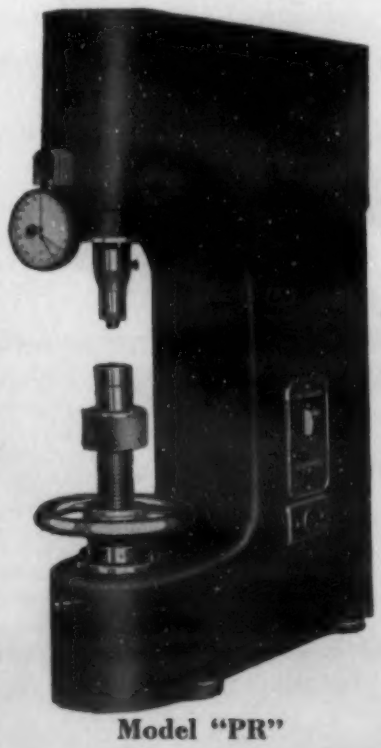
* Endurance limit in water actually slightly higher than that in air.

Fillet radius was approximately 0.02 in. and diameter of filleted specimens approximately 0.300 in.; the holes were approximately 0.04 in. diameter, and diameter of holed specimens approximately 0.400 in. The reduction of fatigue strength contributed by the corrosion in excess of that caused by the stress raiser varied greatly with heat treatment. For the steel tested corrosion-fatigue causes a much greater reduction in strength under cycles of reversed flexural stress than it does under cycles of reversed torsional stress. Ha + HFM (8a)

SCOTT *Improved* WIRE TESTING MACHINE

Autographic Recorder Magnifies Test Line in Stretch Direction

●



Easy to Operate

Adapted specifically to laboratory investigation and research, this improved Wire Testing Machine permits accurate routine Testing without requiring a skilled operator.

Rigid construction eliminates machine deflection; operates with ¼ H.P. Motor to offer ranges of 0-250 and 0-500 lbs.; or 0-500 and 0-1000 lbs.

HENRY L. SCOTT COMPANY
PROVIDENCE, R. I.

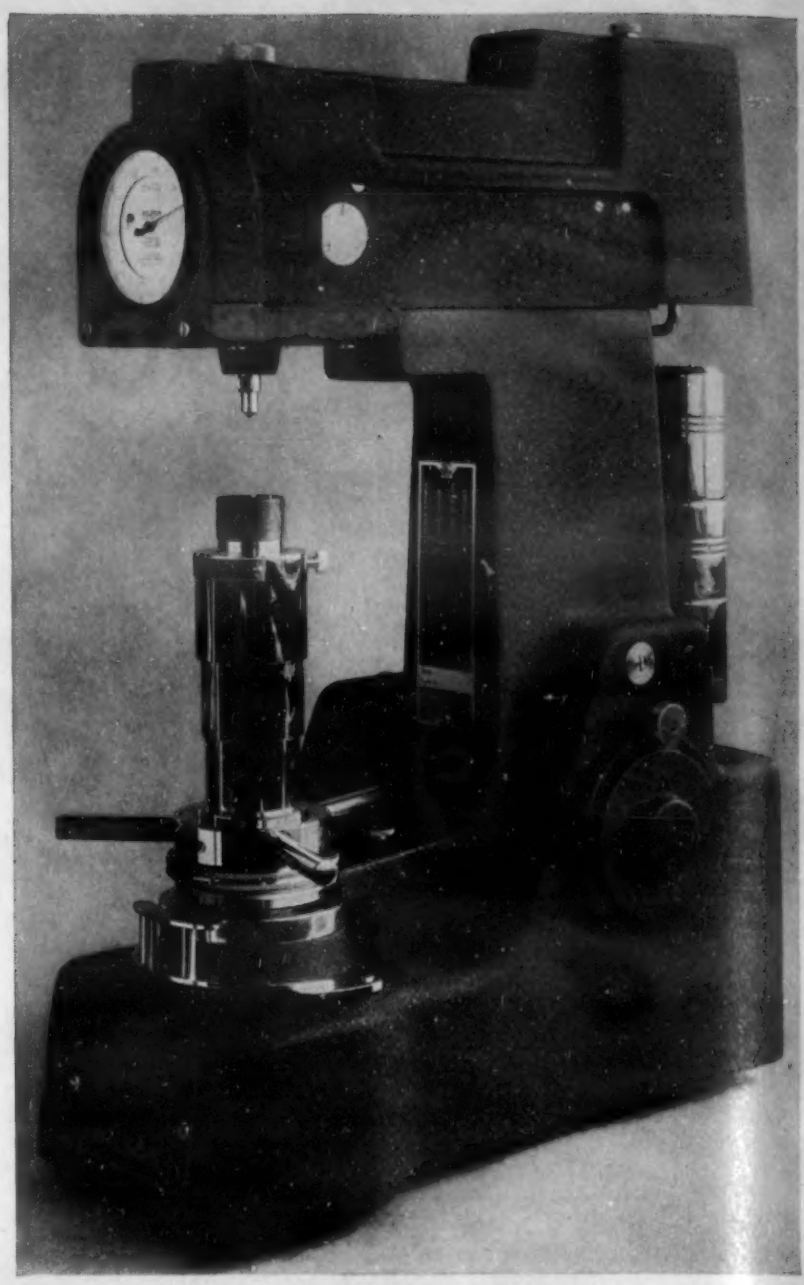
KEEPING PACE WITH PRODUCTION
This modern instrument solves your hardness testing problem

Model "PR"

Capacity — 2600 tests per hour.

Accuracy—Within standard test bar limits.

Tolerance—In excess of .125" variation.



Loading—Major and Minor, DEAD WEIGHT, fully automatic and CONSTANT; 60 Kg; 100 Kg; 150 Kg.

Bulletin on request.

PYRO-ELECTRO INSTRUMENT CO.
7323-5 W. Chicago Blvd., Detroit, Mich.

ROCKWELL
TRADE MARK REG. U S. PATENT OFFICE
HARDNESS TESTER

Motorized Model

Model 3-Q, Motorized for production precision testing.

WHEN making hardness tests you should be looking for trouble—not trouble with or in the tester; not trouble in the method of testing; not trouble in establishing and maintaining calibration of the tester; but trouble in the parts that you are testing. Let no herring get dragged across the trail and keep you looking for the wrong kind of trouble.

Even on quantity inspection few applications of micrometric indentation hardness testing are advantaged by motorized equipment. For these few we make motorized, speedier equipment that maintains genuine accuracy so essential with respect to specified hardness limits. Because of the time consumed in handling and locating the specimen, actual testing is not speeded up anything like as much as some might expect by mechanical operation of the testing machine. We make (for those who can derive real benefit from such apparatus) motorized machines possessed of the universally recognized precision of all our "ROCKWELL" Hardness Testers, and giving readings identical with the readings on hand operated "ROCKWELL" Testers.

Our motorized machines are designed for maximum speed consistent with dependable inspection, which is the only sort of inspection worth doing at all. This applies to both the "ROCKWELL" and "ROCKWELL" Superficial Hardness Testers. Readings are absolutely independent of variations in thickness of pieces tested.

Our field men can and will advise you frankly as to which of our many types best meets your actual requirements. Dependable accuracy is present in all of our models. None of the fundamental patents covering our equipment have expired. They do not expire for years. Many later, important improvement patents also exist and so does our experience in precision instrument making, for today more than ever are we meeting the needs of the metallurgical world and of the men who produce in metal what the whole world is buying.

Our testers are used in many countries and their dependability is everywhere relied upon. That places a considerable responsibility on us but we like the job of meeting it.

9. METALLOGRAPHY

Structure and Constitution. Metallographic Equipment.

J. S. MARSH, SECTION EDITOR

The Nature of Polish. G. I. FINCH. *Trans. Faraday Soc.*, Vol. 33, 1937, pp. 425-430. Original. The fact that polished metal surfaces yield halo patterns by electron diffraction does not show whether the surface layer is amorphous or crystalline, because not only amorphous but also certain crystalline metal films behave similarly. The ability of polished films to dissolve metal crystals supports the view of the amorphous state of both surface flow and polish. Polishing results in the flow of calcite single crystal surfaces. The polished layer is crystalline and integral in structure with the underlying crystal when the surface is a cleavage plane or is close in its direction to that of a cleavage plane, but halo patterns are obtained when the polished surface is steeply inclined to all cleavage planes. Heating leads to the gradual emergence of a single crystal pattern through the eventual replacement of the halo pattern. Surface flow is one of vitreous or liquid-like material, and the crystalline structure of the polished layer on the calcite cleavage plane is due to recrystallization of such fluid material under the influence of the underlying substrate crystal. 15 references. PRK (9)

Plasticity and Mosaic Structure of Crystals (Plastizität und Mosaikstruktur der Kristalle) A. KOCHENDÖRFER. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 299-305. Theoretical. The atomic mechanisms relating translation in crystals to discontinuities in the lattice are reviewed. From energy considerations it is deduced that the separation, L, of these discontinuities is 8.5×10^{-5} cm. in recrystallized Al, in good agreement with the value of 5×10^{-5} cm. proposed by G. I. Taylor. If L is sufficiently small, no plastic deformation should occur below the critical shear stress, but for large values of L, deformation should occur at much lower stresses. During rapid deformation, critical shear stress and work hardening are not sensitive to changes of L. From this reasoning it is concluded that the discontinuities are located on the mosaic boundaries of the lattice. GD (9)

A Relation between the Heat of Fusion of Intermetallic Compounds and their Melting Points and the Calculation of Heats of Formation of Solution (Ueber eine Beziehung der Schmelzwärmen intermetallischer Verbindungen zu den Schmelztemperaturen und über die Berechnung der Bildungs-bzw. Mischungswärmen) O. KUBASCHEWSKI & F. WEIBKE. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 325-326. Theoretical. Known experimental data are used to demonstrate that a proportionality, similar to Trouton's Rule, exists between the heat of fusion and the absolute melting point of intermetallic compounds. This relation is expressed by the equation: Heat of formation [$_{Am}B_n$] — Heat of Solution [$_{Am}B_n$] = 3.5 Absolute Melting Point [$_{Am}B_n$] — (Heat of Fusion mA + Heat of Fusion nB). GD (9)

Automatic Polishing of Metallurgical Specimens Using Cast Iron and Lead Laps. TRACY C. JARRETT (Am. Optical Co.) *Am. Soc. Metals,* Preprint No. 23, 1938, 9 pp. Describes method of automatic polishing of metallurgical specimens. The following sequence of laps and abrasives is recommended: (1) American Optical Co. M303 abrasive on cast Fe lap, (2) M305 on cast Fe lap, (3) 3 successively finer grades of alumina on Pb laps. The abrasives are applied as a paste with kerosene, desulphurized with Hg. The laps are lubricated with kerosene. Apparatus for the levigation of alumina is illustrated. Regular bakelite is employed for mounting. Specimens prepared by this method are flat and free from metal flow. Inclusions are retained HLW (9)

On the Decrease in Mechanical Compressibility of Metals by Alloy Formation (Ueber die Abnahme der mechanischen Kompressibilität der Metalle bei ber Legierungsbildung) F. WEIBKE. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 322-324. Theoretical. Tables are given to show that alloy formation is generally associated with a decrease in compressibility and atomic volume, as compared to that determined from the rule of mixtures. By the precepts of spatial chemistry this decrease occurs largely at the cost of the least noble element in the alloy. When there is little difference between the metals, the rule of mixtures applies. GD (9)

A Method of Preparation of Metallographic Specimens. GEORGE A. ELLINGER & JOSEPH S. ACKEN (Natl. Bur. Standards) *Am. Soc. Metals,* Preprint No. 22, 1938, 15 pp. A method for lapping metallographic specimens in use at the Natl. Bur. Standards is described. Two Pb-Sn (50-50) disks charged with American Optical Co. grades 302 and 303½ emery are employed. These disks are machined flat and contain 1/32 in. grooves ¼ in. apart. They are charged by rotating face down on a cast Fe plate covered with a water-emery mixture. The Fe plate is ground on a precision surface grinder and is grooved. Excess emery not embedded in the alloy disk is removed by brushing prior to use. Advantages of the method are: Rapidity, freedom from surface flow and retention of inclusions. The procedure is of particular value in the preparation of specimens of soft metals. HLW (9)

Electric Conductivity and Structure of Thin Evaporated Metal Films (Elektrishe Leitfähigkeit und Struktur dünner, aufgedampter Metallschichten) L. RIEDEL. *Metallwirtschaft,* Vol. 17, Oct. 21, 1938, pp. 1105-1111; Oct. 28, 1938, pp. 1134-1141. Correlated abstract. Theory and experimental data are reviewed. The J. J. Thomson theory that the specific resistance is not a material constant but a function of the average free path of the electrons and the film thickness is sufficient to explain the relationship between specific resistance and the thickness of the film as long as the film is viewed as being crystalline. The strong influence of included gases on conductivity explains the high specific resistance of thick films as well as the irreversible resistance change upon heating of the film. An amorphous phase of true metals has neither been proved nor positively disproved. 73 references. GA (9)

The Fracture of Cast Iron. I. IITAKA & I. YAMAGISHI. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Oct. 1938, pp. 1025-1033. In English. Original research. The authors classify the fracture of metals and alloys into 4 distinct groups, based on the relation found between the path of fracture and the structural constituents, *i.e.* grain, dendrite, slip band, and twin. Round rods of different sizes were prepared by casting Fe into sand molds and permitting them to solidify at different speeds. The rods were then broken with a hammer. A longitudinal section was polished and etched and its intersection with the fracture surface was microscopically examined. All 60 specimens showed the same type of fracture, the path running along the dendrite boundaries and the fineness of the fractured surface coinciding with the dendrite size. Thirteen samples in which a phosphide eutectic was formed by adding excess phosphorus yielded the same result. The path of fracture does not follow the grain boundaries, and the surface of fracture is much finer than the size of the grains. Samples in which flake graphite was obtained in large sizes show that the path of fracture does not always follow the large graphite flakes, but crosses them very often ,and always follows the dendrite boundaries. Small flakes, appearing usually at dendrite boundaries, lie along the path of fracture. EF (9a)

Rapid Electrolytic Method of Determination of SiO_2 in Steel. ADAM SKRAPSKI, ADAM BIELANSKI & MAREK SOBIESKI. *Hutnik,* Vol. 10, No. 9, 1938, pp. 469-473. In Polish. A review of methods used for determination of SiO_2 in steel points out that complicated apparatus, expenditure of much time, or work with corrosive reagents is required in all cases. The electrolytic method of determination of all non-metallic impurities in steel (see *Hutnik,* Vol. 9, No. 9, 1937, pp. 489-496) was modified. Using samples with a surface not less than 30 $cm.^2$ and a current of 20-25 amps. and up to 12 v., 4-5 liters of electrolyte of composition 10 g./l. NaCl, 100 g./l. KBr and 30 g./l. Na-citrate is passed through the bath, kept at 50-70° C., within 50 min., whereby about 20 g. of the sample dissolves. The results are in good agreement with those obtained by the bromine method. Applicability of the method to production control is indicated. 2 figures and 12 references. JGT (9a)

The Iron-columbium Diagram (Das Zustandsdiagramm Eisen-Niob) H. EGGERS & W. PETER. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch., Düsseldorf,* Vol. 20, No. 15, 1938, pp. 109-203. Original research. The Fe-Cb system was investigated thermally, microscopically, and with X-rays; alloys up to 10% Cb were produced in a high-frequency furnace under a pressure of 10^{-3} mm. Hg; the alloys with higher Cb content were made in the Tammann furnace because of their extremely high melting temperatures. Fe forms an intermetallic compound with Cb, probably of the formula Fe_3Cb_2, melting homogeneously at 1650°-1660° C. A Cb-richer compound of the form Fe_xCb_y exists, although it could not be defined. Fe_3Cb_2 forms with δ-Fe a eutectic at 1356° C. with 17.5-18% Cb, and with Fe_xCb_y at 1560° C. with 67-67.5% Cb. δ-Fe disintegrates at 1220° C. eutectoidally into γ-Fe and Fe_3Cb_2; at 965° C., γ-Fe and Fe_3Cb_2 form Cb-ferrite with about 5% Cb. The γ-field is narrowed greatly. A small amount of Cb added to 18/8 steels prevents intercrystalline corrosion, probably through the formation of a stable Cb-carbide. A comparison of the diagrams of Fe-Cb with Fe-V, Fe-Zr, Fe-Mo and Fe-Ta (shown in juxtaposition) shows for V, Cb and Ta the same tendency to narrow the γ-field. The solubility of the added metal in γ-Fe decreases with increasing atomic radius. V and α-Fe give a continuous series of solid solutions at high temperatures; Cb is soluble in α-Fe at 1356° C. with only 7.05 atomic %, Ta at 1430° C. with 2.28%. The metals of the fifth principal group (of the periodic system) form with Fe an intermetallic compound of a melting point that increases with increasing order number, and, simultaneously, the Fe content of the compound increases, $FeV \rightarrow Fe_3Cb_2 \rightarrow Fe_2Ta$. Zr and Mo show similar behavior, but the solubility increases with increasing order number in both α- and γ-Fe, and all have the same type of composition formula: Fe_3Zr_2, Fe_3Cb_2 and Fe_3Mo_3. Tests and measuring methods are described in full. 9 references. **The Iron Corner of the Iron-columbium-carbon Diagram below 1050° C.** (Die Eisenecke im Zustandsdiagramm Eisen-Niob-Kohlenstoff unterhalb 1050°) *Ibid.,* pp. 205-211. Very exact experiments (described in full) show conclusively that low alloy Cb steels have a space diagram with 2 four-phase planes at 705° and 920° C., respectively. The γ phase decomposes at 705° to α Cb_4C_3 and Fe_3C, while at 920° a non-variant conversion takes place: $\gamma + Fe_3Cb_2 \rightleftarrows \alpha + Cb_4C_3$. The 3-phase region $\alpha + \gamma + Fe_3C$ is very small, so that the composition of the ternary α- and γ-solid solutions at 705° is practically the same as the composition of the binary α- and γ-solid solutions of the Fe-C system at the A_1-temperature. Chemical and X-ray examination proved the carbide to have the composition Cb_4C_3, and a density 7.63. 13 references. Ha (9a)

The Cobalt-manganese-aluminum System (Das System Kobalt-Mangan-Aluminium) W. KÖSTER & E. GEBHARDT. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 281-286. Experimental. The region of the ternary system bounded by the phases, Co-Mn-MnAl-CoAl, was examined by thermal, microscopic and magnetic methods. The CoAl and MnAl phase form a continuous series of body-centered cubic solid solutions, which extend over most of the section, while the CoAl-Mn section constitutes a quasi-binary system. Aside from the CoAl and MnAl solid solutions, face-centered cubic Co solid solutions and Mn solid solutions were observed. The solid solubility of Al and Mn in the body-centered phase fell off sharply with temperature. This phase is ferromagnetic throughout. **The Nickel-manganese-aluminum System** (Das System Nickel-Mangan-Aluminium) *Ibid.,* pp. 291-293. In the region outlined by Ni-Mn-MnAl-NiAl, the Ni-Mn-Al system is structurally analogous to the Co-Mn-Al system. The α solid solution formed over a wide range about the compound MnAl is ferromagnetic. GD (9b)

Solubility of Lead and Bismuth in Liquid Aluminum and Aluminum-copper Alloys. L. W. KEMPF & K. R. VAN HORN (Aluminum Co. of America) *Metals Tech.,* Vol. 5, Dec. 1938, T. P. 990, 12 pp. Original research. The solubility of Pb in liquid Al was found to be 1.52% at the freezing point of Al and to increase continuously with temperature to about 14.75% Pb at 1038° C. The solubility of Bi in liquid Al was found to be 3.36% at the freezing point of Al and to increase with temperature to about 15.19% at 877° C. The freezing point of Al (660° C.) is lowered by the presence of Pb to a minimum of 658.5° C. and by the presence of Bi to 657.1° C. The solubilities of Pb and Bi in solid Al were found to be not more than 0.2% by weight at the melting point of Al, and to decrease with temperature. The solubilities of Pb and Bi in molten Al are decreased slightly by the presence in the alloys of about 5% Cu. JLG (9b)

The modern trend of metallography points definitely towards the PANPHOT because of its following outstanding features:

1. Upright microscope-camera combination which requires a minimum of space.
2. Polished surface of specimen does not come into contact with any support; therefore, scratching is eliminated.
3. Area of illumination on specimen is in full view, and ground glass is visible from sitting position.
4. Universal PANOPAK for brightfield and dark-field illumination in polarised or non-polarised light.
5. Infinity corrected objectives eliminate distortion of image by glass plate in vertical illuminator.
6. Incandescent lamp for visual observation and arc-lamp of high and uniform intensity for photomicrography.

Meets every Requirement of

MODERN METALLOGRAPHY

In the B&L Research Metallographic Equipment, you will have the most complete instrument available for visual observation and photography of metal.

Fitted for bright field, dark field or polarized light work, with magnifications ranging from 4x up to the highest possible with oil immersion objective and high power eyepiece, the B&L Research Metallographic Equipment is adapted to the most exacting work.

Features included are: an especially designed inverted microscope; circular ball-bearing, revolving stage 6″ in diameter; a vertical illuminator of unique design, employing either Tungsten or Carbon Arc; a complete series of objectives and eyepieces for metallographic work; an 8″ x 10″ camera with one meter bellows draw; ball-bearing focusing mechanism; all mounted on shock absorbing stand.

For complete details, write for Catalog E-240 to Bausch & Lomb Optical Co., 634 St. Paul Street, Rochester, N. Y.

MAJOR APPLICATIONS FOR METALLOGRAPHIC EQUIPMENT

1. Approximate Composition.
2. Identification of Structure.
3. Grain Size Classification.
4. Defects and Inclusions.
5. Case Penetration.
6. Segregation of constituents.

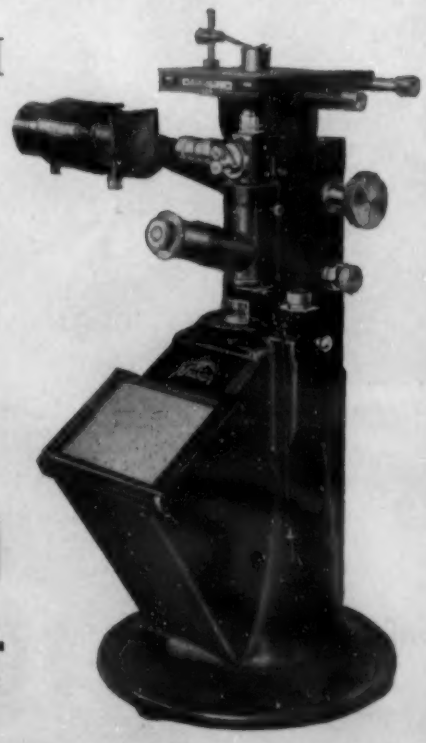
BAUSCH & LOMB

FOR YOUR EYES, INSIST ON BAUSCH & LOMB EYEWEAR, MADE FROM BAUSCH & LOMB GLASS TO BAUSCH & LOMB HIGH STANDARDS OF PRECISION

IF YOU ARE SKEPTICAL

As to the unique resistance of Vitreosil to heat-shock (due to its extremely low expansion) we shall be glad to send a free sample of laboratory ware, for testing, when requested on your business or professional letterhead.

Vitreosil industrial ware possesses the same low expansion and can be used under thermal conditions impossible to other ceramic materials.



High chemical and electrical resistance are further advantages on both laboratory and plant scale.

An X-ray Investigation of Cobalt-aluminum Alloys. A. J. BRADLEY & G. C. SEAGER. *J. Inst. Metals,* Vol. 64, 1938, Advance Copy No. 819, 8 pp. Original research. Al dissolves in the cubic form of Co but not in the hexagonal. It tends to preserve the
1 cubic structure on cooling. After annealing at 320° C. for several days, some of the dissolved Al is precipitated as CoAl, and the residual Co is converted to the hexagonal form. CoAl, which has a body-centered cubic structure, dissolves both Co and Al. The
— lattice spacing, which is a maximum at the ideal composition, falls slowly on the Co side but more steeply on the Al side. In these alloys there are Al atoms at all cube corners, but the cube centers are deficient in Co atoms. Four Al-rich phases were found. Co_2Al_5 has a hexagonal structure containing 28 atoms per unit
2 cell. The existence of a phase of composition Co_3Al_{13} or Co_2Al_9 was confirmed. The addition of Co to this phase does not give a mixture with Co_2Al_5, as has previously been supposed. The phase
— in equilibrium with Co_3Al_{13} has the approximate formula Co_4Al_{13}. It has a very complicated X-ray pattern, which is quite different from those of either Co_3Al_{13} or Co_2Al_5. Photographs of alloys near the composition $CoAl_3$ indicate the existence of yet another phase, but this has not been isolated. JLG (9b)

3 **The Intermediate Phases in the Aluminum-copper System after Slow Cooling.** A. J. BRADLEY, H. J. GOLDSCHMIDT & H. LIPSON. *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 816, 13 pp. Original research. The phase sequence for slowly-cooled Al-Cu
— alloys containing from 16 to 30% Al was checked by X-ray methods. γ (Cu_9Al_4), γ_1 ($Cu_{32}Al_{19}$) and γ_2 (Cu_3Al_2 are considered to be the same single-phase field, since it is impossible to find a $\gamma + \gamma_1$ or $\gamma_1 + \gamma_2$ phase field. The 3 structures have different superlattices, but are otherwise of the same type, though γ_1 and
4 γ_2 deviate slightly from cubic symmetry. ζ (Cu_4Al_3) and η (CuAl) are totally distinct phases, separated by definite 2-phase regions. Representative specimens of $\gamma + \zeta$, $\zeta + \eta$, and $\eta + \Theta$ have been
— identified. ζ and η have been reported to exist in 2 forms. The alloys here described presumably belong to the low-temperature modifications. Their structures are more closely related to that of Ni_2Al_3 than to γ, though all are derived from a simple body-centered cubic lattice by the omission of atoms from certain of the lattice points, and by the formation of superlattices. JLG (9b)

5 **The Magnetic Susceptibility of Gold-copper, Gold-silver, Silver-copper and Copper-nickel Alloys** (Sur la Susceptibilité Magnetique des Alliages Or-cuivre, Or-argent, Argent-cuivre et Cuivre-nickel) W. BRONIEWSKI, S. FRANCZAK & R. WIKOWSKI. *Ann. Phys.,* Vol. 10, July/Aug. 1938, pp. 5-19. Original research.
— Chemically or electrolytically purified metals were used for making the binary alloys that were submitted to tests of magnetic susceptibility. The application of this method is highly recommended,
6 as it may yield information, as in the case of Cu-Au alloys, not obtainable by other standard methods. Au-Cu alloys quenched from high temperatures form a continuous series of solid solutions. In the annealed state, 2 constituents occur: AuCu and $AuCu_3$. In
— the experimenters' tests, the range of mixtures of both constituents is clearly defined; also, the limit where AuCu changes its rôle of
7 solvent to that of solute can be recognized. The Au-Ag diagram, showing susceptibility in relation to chemical analysis, presents a curve slightly concave to the axis of composition (solid solution type) and the Cu-Ni graph shows a continuous passage of the alloys from the ferromagnetic to the paramagnetic state. A nearly straight line was obtained in the Ag-Cu system. EF (9b)

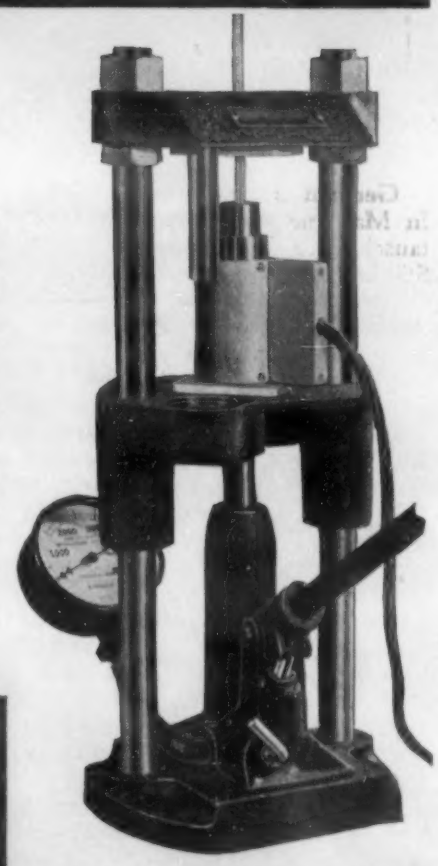
— **The Manganese-aluminum System** (Das System Mangan-Aluminium) W. KÖSTER & W. BECHTHOLD. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 294-296. Experimental. The alloys of Al-Mn system were examined in the composition range from 30 to 100% Mn by thermal, magnetic and microscopic methods. The terminal,
8 high temperature δ-Mn phase dissolves up to 17.5% Al and has a melting point maximum at 13% Al. The body-centered cubic compound AlMn forms at 1160° C. by the peritectic reaction melt + $\delta \rightarrow$ AlMn. It extends over the range from 48 to 67% Mn and is
— ferromagnetic with a Curie temperature of 70° C. Microscopically, it shows profuse twins. Another peritectic reaction, AlMn + melt $\rightarrow$ Al_2Mn occurs at 1095° C. The δ-γ and γ-β transformations of Mn are lowered by increasing amounts of Al. At 1005° C. the
9 eutectoid decomposition $\delta \rightarrow \gamma$ + AlMn occurs, while at about 930° the γ phase has a eutectoid reaction, $\gamma \rightarrow \beta$ + AlMn. β Mn takes about 13% Al into solid solution, however, due to the β-α transformation, Mn holds only about 5% Al in solid solution at room temperature. GD (9b)

— **Magnesium-rich Mg-Al-Ag Alloys.** HIDEO NISHIMURA & HACHIE SAWAMOTO. *Suiyokwai-Shi,* Vol. 9, Oct. 1938, pp. 645-654. In Japanese. The constitution of the Mg-rich alloys con-
10 taining Al and Ag was investigated by means of thermal analysis and microscopic examination. From various constitutional sections taken through the Mg axis, the following conclusions were drawn: (1) In a range of Al 50% and Ag 50%, there exist the primary separations of (Mg), δ (Mg_2Al_4) and Mg_2Ag. (2) The uni-variant reaction lines were found to be: Liq $\rightleftarrows$ (Mg) + δ, Liq $\rightleftarrows$ (Mg) + Mg_2Ag, and Liq $\rightleftarrows$ (Mg_2Ag) + δ. (3) The non-variant point was: Liq $\rightleftarrows$ (Mg) + δ + Mg_2Ag at 404° C. HN (9b)

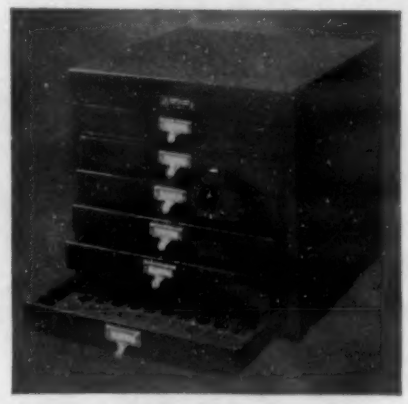
Precision Determination of Lattice Constants of Non-cubic Substances (Bi, Mg, Sn) by the Asymmetric Method (Die Präzisionsbestimmung von Gitterkonstanten nichtkubischer Stoffe (Bi, Mg, Sn) nach der asymmetrischen Methode) A. IEVINS, M. STRAUMANIS & K. KARLSONS. *Z. physik. Chem.*, Abt. B, Vol. 40, Aug. 1938, pp. 347-356. Original research. The lattice constants of Bi, Mg and Sn were redetermined by the "asymmetric" powder X-ray method of Ievins & Straumanis (*Z. anorg. allgem. Chem.*, Vol. 238, 1938, pp. 175-188.) The metal samples were pulverized, annealed at 220° C. for 2 hrs., spread thinly on a glass rod, 0.05 mm. diam., and exposed in a camera for 57.4 mm. diam. with thermostatic temperature control, using different radiations. The choice of radiation, the conditions for greatest accuracy, and the procedure of measuring films are dealt with at length. The error does not exceed 0.001%. Purest Bi from Kahlbaum was finely powdered in an agate mortar and exposed to Cu radiation at 26.46° C. Using the coefficients of thermal expansion of $Bi_{II} = 16.2 \times 10^{-6}$ and $Bi_{I} = 12.0 \times 10^{-6}$, the measured values were reduced to: $a = 4.53674 \pm 0.00004$ A.U., $c = 11.83834 \pm 0.00004$ A.U., $c/a = 2.60944$, at 25° C. Purest available Mg from the Cie. des Produits Chimiques et Electrométallurgiques, Alais, Froges et Camargue, with 99.995% Mg, 0.0006% Fe, 0.0010% Si, 0.0013% Cu, 0.0012% Al, 0.0007% Cl was powdered by scraping with a porcelain shard and exposed to Fe or Ni radiation at 26.61° or 27.08° C. Using the coefficients of thermal expansion of $Mg_{II} = 27.1 \times 10^{-6}$ and $Mg_{I} = 24.3 \times 10^{-6}$, the measured values were reduced to: $a = 3.20280 \pm 0.00003$ A.U., $c = 5.19983 \pm 0.00005$ A.U., $c/a = 1.62353$, at 25° C. Filings of Sn were exposed at 13.97° C. and other temperatures. From the measurements the coefficients of thermal expansion of Sn were found as: $Sn_{II} = 32.24 \times 10^{-6}$ and $Sn_{I} = 16.77 \times 10^{-6}$, and the lattice constants as: $a = 5.81970 \pm 0.00002$ A.U., $c = 3.17488 \pm 0.00005$ A.U., $c/a = 0.54554$, at 25° C. The present values agree best with those of Jette & Foote (See *Metals and Alloys*, Vol. 7, June 1936, p. MA 311 L/8). ORS (9b)

Investigation of the Structure of the Compound of Beryllium with Chromium. M. I. ZAKHAROVA & P. I. DAL'NOV. *Zhur. tekh. fiz.*, Vol. 8, Feb. 1938, pp. 252-255. In Russian. Original research. Two mixtures of Cr and Be in the atomic proportions 1/1 or 1/2 were melted, respectively, in a Be_2O_3 crucible in a vacuum high-frequency induction furnace, or in a MgO crucible in a Tammann furnace. Large crystallites removed from the center of the slowly-cooled reguli and containing, respectively, 56.5 or 68.77 atomic % Be, were subjected to X-ray analysis by the pinhole method. After being powdered and annealed, they were also investigated by the X-ray powder method using Cr radiation. In both alloys the crystal lattice was found to be of the hexagonal type belonging to space group D^4_{6h} or D^6_6, the lattice constants being $a = 4.258$ A.U., $c = 6.982$ A.U. in the first, and $a = 4.260$ A.U., $c = 6.982$ A.U. in the second alloy. The authors conclude from these data that in the Cr-Be phase diagram, at lower temperatures, the composition interval from 56.5 to 68.77 atomic % Be is occupied by the region of a single intermetallic phase of the type AB_2 with a hexagonal crystal lattice, analogous to $MgZn_2$, whose constants do not vary within this interval. The crystal lattice of a compound of this type contains 12 atoms per unit cell in the following positions: (A) 1/3, 2/3, -v; 1/3, 2/3, 1/2 — -v; 2/3, 1/3, 1/2 + -v; 2/3, 1/3, — -v; (B_I) O, O, O; O, O, 1/2; (B_{II}) u, -u, 1/4; 2u, -u, 1/4; u, 2u, 1/4; -u, u, 3/4; 2u, u, 3/4; -u, 2u, 3/4. Assuming that, in the alloy with 56.5 atomic % Be, 4 Cr atoms occupy the positions (A) and 1.2 Cr atoms and 6.8 Be atoms are statistically distributed over the positions (B_I) and (B_{II}), the best agreement between observed and calculated intensities of the interference lines was obtained with the parameter values u = 1/6, v = 1/16. ORS (9b)

The Solubility of Chromium in Aluminum (Ueber die Loslichkeit von Chrom in Aluminium) W. KOCH, FINOW & H. WINTERHAGER. *Metallwirtschaft*, Vol. 17, Nov. 4, 1938, pp. 1159-1163. Research. The solubility of Cr in Al was investigated, using resistivity, dilatometric and lattice parameter measurements. All 3 methods checked within experimental error limits. The solubility line is reported at a slightly higher concentration of Cr than that established by Fink and Freche, whose curve was determined microscopically. Maximum solubility is at 0.87% Cr. At low temperatures, resistivity measurements were reliable for solubility measurements, while at high temperatures the X-ray method was most satisfactory. GA (9b)



The Bi-Sn Diagram. T. SATÔ & T. MATUHASI. *Nippon Kinzoku Gakkai-Si*, Vol. 2, Dec. 1938, pp. 592-597. In Japanese. Original research. By various metallographic methods the nature of the proposed intermetallic compound called variously $BiSn_7$, Bi_3Sn, or $BiSn_2$, was clarified. Although discontinuities were observed at about 95° C. in the curves of electric resistance and volumetric dilatation, none was observed in the curves of differential thermal analysis, nor did X-ray analysis confirm the existence of any intermetallic compound in this alloy system. The anomaly is due to the abrupt change in solubility of Bi in Sn solid solution. NS (9b)



METALLURGICAL MOUNTINGS

AB

SPECIMEN MOUNT PRESS

Pioneers a new technique for the metallurgist, and solves the problem of specimen mounting. It eliminates differential etching action frequently encountered with fusible alloys. The advantages of extreme edge studies, convenience in handling, speed and economy, contribute to the popularity of the new AB Specimen Mount Press.

ALL STEEL SECTIONAL AB SPECIMEN CABINET

provides convenient storage space for 600 specimens per 6-drawer section. Indexed spacers keep each specimen in its own compartment.

TRANSOPTIC MOUNTINGS

The dream of the metallurgist became true with our introduction of the transoptic mounting technique. For visibility of specimen from all sides, for ease in making electrical connections in electrolytic etching, Transoptic mountings are a definite step forward.

German Substitution of Non-ferrous Metals and Alloy Steels in Machine and Apparatus Construction (Einiges über die austauschweise Verwendung von Nichteisenmetallen und legierten Stählen im allgemeinen Maschinen- und Apparatebau) WILLI CLAUS. *Beiträge zur Wirtschaft, Wissenschaft und Technik der Metalle und ihrer Legierungen,* No. 3, 1938, 79 pp. Survey covering the application of non-ferrous metals and alloys within the frame of the 4 year plan, gives production data, consumption, composition, properties and general application of Cu, Ni, Pb, Sn, Zn, Al, Mg and their respective alloys and of Ni and Cr-Ni steels and Cr and Cr-Mo steels, dealing at length with the possibilities of their replacement by other alloys. (1) *Cu and its alloys:* The outstanding properties of hard Cu alloys, useful in apparatus and machine construction, and the increasing application of Cu-clad metals and alloys are stressed. Interesting examples of material-saving without quality impairment are given. The application of the standardized cast Sn bronzes should be dispensed with and they should be replaced by red brass, Pb bronzes, special brasses, Zn, Al and Mg alloys. All cast bronzes should be alloyed with 2% Zn which will not impair chemical and mechanical properties. Also, wrought Sn bronzes can be reasonably replaced by other, and cheaper, alloys. Among the red brasses the alloy Rg 5 (85% Cu, 5% Sn, 7% Zn, 3% Pb is expected to become in time the only red-brass alloy applied in Germany, in comparison with 5 standard types at present. The considerable recent progress in compound castings of red brass/steel is pointed out. Among special bronzes the advantageous application of cast and wrought Al bronzes instead of Sn and similar bronzes is outlined. Pb bronzes are suitable substitutes for all kinds of bearing bronzes with high Sn content, since their running properties are by far superior to the latter. The question of the replacement of As bronzes for fire boxes by Fe is not yet definitely settled. The casting brasses GM_8 58, 63, and 67 are suitable as replacing materials for simple red brasses. To a large extent the casting brasses are replaceable by Zn-containing light metal (Al, Mg) alloys. The wrought brasses and Tombak alloys may be replaced by corresponding alloys with Zn, Al or Mg as base metal. Present developments tend to decrease the use of brass, *e.g.* in the field of sheet metal consumption. As regards their composition, no change is to be observed in the field of brazing alloys. Cd-Zn solders are well suited to steel brazing. In the field of the tableware industry certain types of rustless steel seem able to replace Ni-silver. (2) *Pure Ni and its alloys:* Pure Ni can be saved by using Ni-clad steels and better galvanizing processes. The high Ni contents of Ni-Cu alloys can be decreased without impairing mechanical, chemical and optical properties. The 70% Cu-30% Ni alloy frequently used for condensor tubes can be replaced by special Al-bearing brasses. Ni and Ni alloys should be replaced as far as possible by light metal alloys, rustless steels, etc. Instead of Ni-plating, Cd-plating, bright Ni-plating and phosphate deposits are suitable. (3) *Pb and its alloys:* Soft Pb has been wasted in the past, and may suitably be replaced by stronger Pb alloys, thus making possible considerable weight savings. High-Pb white bearing metals have totally replaced high-Sn bearing metals. In many cases Pb and its alloys have successfully been replaced by Zn, Al and Mg alloys, or by organic materials. (4) *Sn and its alloys:* Sn replacement has been referred to under (3). Soldering Sn can be replaced but to a minor extent. Sn die-casting alloys are replaced by Zn, Al and Mg alloys, and organic materials. (5) *Sand and die cast Zn alloys:* These are the recommended substitutes for simple Sn bronzes and brasses, Al bronzes and the like. On the other hand Zn die casting alloys can themselves be replaced by Al and Mg die-casting alloys. Wrought Zn alloys also find increasing application. (6) *Al and its alloys:* These should be much more widely used; Al, for instance, for making surfaces of high reflectivity, or as cladding material on Cu (Cupal); Al casting alloys as bearing materials; Al wrought alloys as free-cutting stocks and as self-hardening Al alloys of high tensile strength for cladding. (7) The application of *Mg and its alloys* is well known so that no further remarks are required. (8) *Cr and Cr-Mo steels:* In this field the author refers in particular to American experience. 63 references.

6 **Bearing Metals.** F. A. FOX. *Machinery, London,* Vol. 53, Oct. 27, 1938, pp. 105-109. Comprehensive review. Requirements of bearing metal are: (1) Low coefficient of friction; (2) resistance to wear; (3) strength and plasticity at working temperatures; (4) robustness; (5) resistance to corrosion; (6) high fatigue strength; and (7) strong bond. Alloys used are: (1) Cu base alloys (usually without a backing); (2) white metals; (3) Pb with Ba, Ca or both; (4) Sn alloys; (5) Cd with Ag, Ag + Cu or Ni (except 7 for corrosion resistance, Cd-Ag-Cu is one of most promising recent innovations); (6) molded bearings from powdered metals with controlled porosity. Shells may be made from cast Fe, steel or bronze. Bronze is being replaced by steel, owing to the higher strength of the latter, although bronze has the following advantages: (1) Safeguards shaft in case of failure of bearing; (2) usually bonds better with Sn-base alloys; (3) has coefficient of expansion nearer to that of bearing metal; and (4) has lower modulus, which is sometimes helpful. 8

JZB (10)

Initial Susceptibility, Magnetization and Permanent Deformation (Susceptibilité Initiale, Aimantation et Déformation Rémanentes) ALBERT PERRIER. *Helv. Phys. Acta,* Vol. 11, June 18, 1938, pp. 360-362. Original research. Experimental determination of the values of the constants a and b in the expression a + bH for the initial magnetic susceptibility of Ni and mild steel in the presence of remanent magnetization either parallel or normal to the field. For Ni, these values were also determined 9 after compression of 0.5% and 1%. The reversible part of the susceptibility is increased by a transverse remanent magnetization and decreased by a parallel remanent magnetization; the irreversible part is decreased in both cases.

EF (10)

Some Factors that Affect the Quality of Electrical Heating Wires. T. EDUKA. *Nippon Kinzoku Gakkai-Si,* Vol. 2, Dec. 1938, pp. 609-617. In Japanese. Original research. With some 16 commercial Ni-Cr and Ni-Cr-Fe wires, the effects of certain 10 factors on strength and electrical resistance were studied. The tensile strength and electrical resistance were much more influenced by working conditions, heat-treatment and surface finishing than by chemical compositions; that is, greater working ratio, smaller grain size and less surface defects give longer life of wires.

. . . and the Tank is 900 Lbs. Lighter

Truck tank built of Dyn-el by PENNSYLVANIA FURNACE & IRON CO., Warren, Pa., for Wm. F. Crossett, Inc., of the same city . . . 3-compartment, 4,100 gallon, semi-trailer type.

Because of its greater strength and better fabricating properties, "A. W." Dyn-el is selected for use in the construction of this new type of truck tank . . . Built of hot rolled carbon steel, this 4,100 gallon tank, including manholes, piping, emergency valves, catwalk, hose tubes, trim skirting and under framing, weighs 5,200 pounds. Built of "A. W." Dyn-el, it weighs only 4,320 pounds—a saving in hauling costs of 900 pounds on the tank alone... and this lighter tank is actually stronger than the heavier job and has greater resistance to shock, fatigue and corrosion.

The 48-page book, "A.W." Presents Dyn-el, gives full details of savings in weight and cost possible with this new high-strength, flat-rolled steel. Diagrams, tables and charts cover a wide range of tests and properties. To executives, this book gives a quick picture of performance and costs. To engineers, it gives complete fabricating and design properties and table of sizes and weights. We will be pleased to send you a copy.

Materials Research as Reflected by the Lilienthal Society for Aviation Research (Werkstofforschung im Spiegel der Lilienthal-Gesellschaft für Luftfahrtforschung) ADRIAN. *Automobiltech. Z.*, Vol. 41, Dec. 25, 1938. Review plus original research. Experiments on age-hardening of Al-Cu-Mg alloys showed that alloys with low Cu-content and higher Mg content age harden much slower than regular Duralumin. At 20° C. noticeable hardening begins 12 hrs. after quenching. The characteristic structural feature of the ordinary free-machining materials is the presence of heterogeneous inclusions that act as chip-breakers. For the purpose of developing free-machining light alloys the following were tried: (1) To add insoluble soft metals and (2) to obtain a structure with a hard primary precipitate. Pb is applied mostly as the insoluble soft addition, and a process has been developed according to which Pb is distributed evenly through the melt. The best cutting properties for age-hardening alloys were found to exist in the hardened state. Al-Cu-Mg alloys are usually aged at room temperature. At higher temperatures, properties such as hardness and yield point are greatly improved, but the fatigue limit is lower and the notch effect greater. At those temperatures and periods which yield maximum value for yield point and hardness, the metal is outside the temperature range of susceptibility to intercrystalline corrosion. The corrosion resistance can be increased by plating with Cu-free Al-alloys or pure Al. Surface oxidation (Eloxal-process) should not be carried out in the artificially-aged state, but between quenching and reheating. The fatigue strength, tensile strength, yield strength and elastic limit increase with decreasing temperature. The drop in strength under dynamic stress is greater for Al-Mg than for Duralumin, when the original fatigue strength of smooth specimens was equal. An Al-Mg alloy containing Zn and Cr showed good resistance to intercrystalline corrosion when tested with 3% Na-Cl solution with H_2O_2-addition and under saltwater spray. The stress-corrosion of Zn-containing sheets even after annealing up to 100° C. is considerably lower than that of the plain material. It is claimed that low-Ni steels for crankshafts are equal to high-alloy steels; the fatigue limit is the same. By proper design a crankshaft from low-strength, practically non-alloy material can meet fatigue stress requirements in airplane engines. Improvement of pistons by surface treatment was tried. No advantages were obtained by oxidation (Eloxal-process). Sn coating is already in practical use. Tests are being run with coats of plastics and of Pb. Surface oxidation of the bottoms of pistons reduces the heat absorption, and thus protects against overheating. Tests are under way with Cr and Ni coatings. The bending fatigue limit gives no measure of the endurance of piston alloys at elevated temperature. "Growth" of piston rings could not be noted below 450° C., so that no danger exists in practical operation. Welding of Al-Mg and other Al-alloy sheets can be used instead of riveting. Annealing between 60°-330° C. after welding is advantageous; for some alloys a previous annealing must be applied. Investigation of non-destructive testing methods led to the following observations: Short time stressing above the fatigue limit causes lattice changes; below the fatigue limit no changes were observed. Small disturbances were detected close to the fatigue limit. RPS (10)

Cylinder Sleeve Linings (Was halten Sie von Zylinder-Laufbüchsen?) G. BAUMGART. *Motorwelt*, Vol. 36, Dec. 1938, pp. 920-923. Practical. The idea of providing interchangeable cylinder linings is old, but the linings must be of a higher grade material than the block to justify the increase in work and cost. By additions of Ni, Cr, Mo, Cu, etc., improved cast irons were created for this purpose. Ni-alloy casting with C as flaky graphite shows good wear resistance. The Fe used for cylinder linings is melted in cupolas, then refined and alloyed in electric furnaces, and the pieces are made by centrifugal casting, producing a very dense material, free from pores. The sleeves are taken out of the mold red hot. A series of machining operations follow. The practical importance is based on the possibility of using ordinary casting for the block and special alloy casting for the cylinder linings. RPS (10)

Magneto-electrolytic Method for Producing Marked Anisotropy (Méthode Magnétoélectric pour Réaliser de Fortes Anisotropies) A. PERRIER & C. MERMOD. *Helv. Phys. Acta*, Vol. 11, July 18, 1938, pp. 362-364. Original research. The anisotropic behavior of Co electrolytically deposited in a magnetic field of several hundred oersteds was studied. The pronounced orientation of the electrodeposits corresponds in an alternating field with the axis of the alternating field, and the deposit behaves like a single crystal whose axis is arranged along the line of easiest magnetization. The anisotropy of the deposits, which are magnetically very hard, can be demonstrated by scratching with a graving tool. The thermal stability of the anisotropy is remarkable. No change occurs during several hours annealing at 1200° C. **Magneto-electrolytic Anisotropies** (Anisotropies Magnétoélectrolytiques) *Ibid.*, Oct. 15, 1938, pp. 468-469. Original research. The previous experiments on Co (see foregoing abstract) were extended to the other 2 ferro-magnetic metals, *i.e.* Ni and Fe, and the same phenomena were observed as with Co. EF (10)

M. GENSAMER, SECTION EDITOR

1 **On the Properties of C-rich Fe-Mn-C Alloys, in Particular their Applicability as Hard Alloy** (Ueber die Eigenschaften kohlenstoffreicher Eisen-Mangan-Kohlenstofflegierungen, insbesondere ihre Verwendbarkeit als Hartmetall) GÜNTHER HAENSEL. *Doctor's Thesis, Tech. Hochschule Breslau*, 1938, 30 pp. Original research. Hardness determinations, microscopic, X-ray, annealing and nitriding experiments and cutting tests were used to investigate the applicability of Fe-C-Mn alloys, with C contents of from 2.67-4.17% and Mn contents of from 1-5%. Variable hardnesses are attained with constant C and Mn content, depending on the cooling conditions in casting the alloys. The hardness increase with increasing C content is caused by the increasing formation of carbides. The microscopic investigations show that pearlite formation is rendered more difficult with rising Mn content. With the disappearance of the pearlite transformation at about 5% Mn and subsequently the disappearance of α-Fe, a solid solution of carbides in γ-Fe is present at these Mn contents. The X-ray examination substantiated these microscopic findings. The presence of troostite in the alloys of 1-3% Mn gave the α-Fe lattice. In the annealing experiments to improve the properties of the alloys, the highest hardness improvement was attained with the 5% Mn-3.9% C alloy after 1-hr. annealing at 750° C. The cutting tests substantiated the results of former investigations by Sauerwald & Kubik (Doctor's Thesis, *Tech. Hochschule Breslau*, 1930). The "radiated crystals" formed upon casting the alloys in Fe molds were to stand vertically to the cutting edge. 30% better cutting results were achieved upon casting the alloys in water cooled Cu molds. Best cutting results were given by the 5% Mn alloy in the annealed state. The cutting capacity of this alloy corresponds to that of an 18% W high speed steel. The nitriding experiments (500° C., 120 hrs.) on 2 alloys of 2.5% Mn, 3.44% C and 5% Mn, 3.82% C, respectively, proved unsuccessful, probably due to the presence of highly stable Mn carbides. GN (10a)

2 **Magnetic Hysteresis in Single Crystals. Preliminary Communication.** YA. SHUR & R. YANUS. *Zhur. eksp. i teor. fiziki*, Vol. 8, Jan. 1938, pp. 67-69. In Russian. Original research. The normal component of magnetization with reference to the direction of the external field, in relative units, and the coercive force of single crystals and polycrystalline samples of transformer steel with 3.5% Si were determined. The single crystals were cut out from strips of sheet cold deformed by stretching and subsequently recrystallized at high temperatures; the magnetic measurements in all crystallographic directions could be made on the same specimen. The normal component of magnetization was determined at a field of 600 oersteds. The coercive force was measured, after an initial magnetization of 800 oersteds, by the force of the reverse current in the solenoid at which the expulsion of the specimen from the measuring coil produced no deflection of the ballistic galvanometer. The *preliminary results* given in this paper show that, in single crystals, the coercive force varies with the crystallographic orientation within the limits of 0.1 and 0.3 oersteds, in agreement with the findings of Ruder (see *Metals and Alloys*, Vol. 5, Nov. 1934, p. MA 533) and Sixtus (*Phys. Review*, Vol. 50, 1936, p. 395). The anisotropy of the coercive force has a complex character differing greatly from that of the magnetic permeability, and does not obey Ruder's formula. In polycrystalline samples, the coercive force is nearly uniformly about 0.4 oersteds at small grain sizes of up to 1 to 2 mm., but decreases greatly as the grain size increases, attaining the value of about 0.2 oersteds, *i.e.* the mean value for single crystals, at a grain size of 3 to 4 mm. 3 **The Development of the Grooved Rail. A Contribution to the History of Rail Manufacture** (Die Entwicklung der Rillenschiene. Ein Beitrag zur Geschichte der Schienenfabrikation) ARTHUR TIX. *Tech. Blätter*, Vol. 28, Sept. 18, 1938, pp. 544-546. Paper considers the history from the standpoint of metallurgical quality improvement, outlining the different welding methods applied, discussing the mechanical properties of head-hardened rails, of wear resistant natural hard rails of high C, or of high C and Mn content, of wear resistant Mn, Cr, V and Mo alloyed rails and of compound rails. Compound rails cannot be dispensed with for tramways. GN (10a)

4 **The Brake Shoe, an Outline of its History and Development.** M. N. TRAINER. *Southern & Southwestern Railway Club Proc.*, Vol. 26, Jan. 1938, pp. 8-27. An historical description of the materials used in brake shoes, and how modern steels have helped to shorten time and distance of stopping heavy trains by increasing the friction and at the same time increasing the heat capacity and heat-dissipating property. Cast Fe is today the only material that is used successfully for the body of the shoe itself, no other material tried being equal to it. Ha (10a)

National Steel high tensile alloy combines high strength with unusual

Ductility

ITS INHERENTLY FINER GRAIN MAKES ALL THE DIFFERENCE

The active and widespread interest in National Steel high tensile alloy can mean only one thing—that users have found in this finer-grained steel the DUCTILITY that is absolutely essential if full advantage is to be taken of all the other desirable characteristics of a high tensile steel.

Because of its exceptional DUCTILITY, this high tensile steel is constantly finding important new uses. It has been cold pressed into difficult stamped parts, such as automobile wheels, and has given excellent results in other similarly difficult applications. In the majority of cases no change in shop practice is necessary.

Practically non-aging, with a high resistance to impact and fatigue at both normal and extremely low temperatures, with exceptional weldability, and with corrosion- and abrasion-resistant properties, this high tensile, HIGH DUCTILE steel may solve your own engineering and production problems.

National Steel high tensile alloy is available in sheets, strip, plates, bars and shapes.

Our engineers will be glad to work with you in applying this steel to your specific requirements. Inquiries are invited.

The Mechanical Qualities of Open-hearth Steels. KÊZIRÔ KUROKAWA. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Oct. 1938, Part II, pp. 1322-1355. In English. Extensive review and original research. The object of this investigation was to help the "national policy of a Ni-short country" (Japan) by "quickly changing the focus of alloy steel technique from Ni series to Ni-free chrome series." The author concludes, "Unless these experimental data are distrusted, we need no longer depend on Ni to get a steel of high mechanical quality; changing to Cr and Mo will effect excellent strength and toughness of steel. Moreover, most of the defects that used to be fatal in steel objects are expected to be gotten rid of by giving up Ni in steel." The experiments were carried out with small objects to be certain of obtaining a rapid quench. It is admitted that the "results can not be directly applied as true in the case of large objects." Chemical analyses are given and the testing results are clearly arranged in 21 diagrams. The first set shows changes of yield point, tensile strength, elongation, contraction and impact value in relation to tempering temperature for the following group of steels: C-steel and Ni (3.5%)-steel, Ni-Cr and Ni-Cr-Mo steel (3 different analyses), Cr-Mo steels (2 grades). The minimum impact value of the Ni-Cr steels is much lower than that of Ni-Cr-Mo. Mo (0.5%) diminishes temper brittleness and induces toughness. The minimum impact value of Cr-Mo steel is found at a higher temperature than that of Ni-Cr-Mo. After tempering above 400° C., the impact value of Ni-Cr-Mo steel is inferior to that of Cr-Mo steel. The tempering temperature of the latter can be raised to 750° C. or more since Ac_1 is elevated by the preceding quenching. Thus, the mechanical properties can be controlled to a wider extent. The impact value of Cr-Mo steel increases with the Cr content up to 3% over a large tempering range. In C steel, the impact value will gradually decrease as the tempering temperature is raised above 200° C. In Ni-Cr steel, a minimum generally occurs at about 300°-350° C., but when Cr is high, this minimum seems to move to higher temperatures, reaching 500° C. when Cr is over 8%. A second series of 8 diagrams correlates impact value and tensile strength of more than 50 Japanese steels. Cr-Mo steels containing 2.0-3.0% Cr and 0.5% Mo offer the best combination of high tensile and impact strength. The undesirable effect of C is not very pronounced in this type of steel. Ni steels are not safe from white spots, even in the presence of the supposedly harmful Cr or Mo. If C is controlled adequately, higher Cr steels are relatively free from white spots and "practically safe" above 2.5% Cr. The Cr-Mo steels are considered to be a match for Ni-Cr-Mo. It is better to use no Cr at all and increase C and Ni than to use inefficient amounts of Cr. A 2% Cr-0.5% Ni steel is better than a 2% Ni-1% Cr steel. Some of the laboratory experiments were checked on castings of over 20 tons. Ni steel was not found "good enough for uniform quenching." Ni-Cr steels were a little tougher than Ni steels. The results on Ni-Cr-Mo checked the experimental findings, and its quenching characteristics were superior to those of Ni or Ni-Cr steel. The low Ni, medium Cr steels show excellent quenching effects, indicating that it is better to increase Cr rather than Ni. It is superfluous to add more than 1% Mo. 0.5% Mo is sufficient to confer self-hardening. The results on creep show that Ni detrimentally affects this property.
EF (10a)

Copper-steel Castings. MARTIN ALEXANDER. *Iron Steel Inst., Third Report Steel Castings Res. Committee,* 1938, pp. 61-72. Original research. The effect of 1% Cu was investigated in cast steels containing a little less than 0.3% C with high and low Mn contents, with 0.8% Cr, 1.5% Ni and 1.5% Ni together with 0.5% Cr. Results, including the macroscopic examination of castings, indicated that Cu is a valuable alloying element in steel castings. It improves the mechanical properties of the annealed steels and renders the castings susceptible to a hardening treatment that can be carried out at a temperature below the critical range without distortion or the setting up of internal stresses. The full effect of the temper-hardening treatment cannot be carried out on account of the accompanying embrittlement. To avoid an undue fall in impact strength, it is necessary to keep the C low and to heat at a temperature higher than that giving maximum hardness. With a carefully balanced composition and suitable treatment very good mechanical properties may be secured in castings by the addition of Cu to a variety of low-alloy steels. JLG (10a)

Specific-heat/Temperature Curves of Commercially Pure Iron and Certain Plain Carbon Steels. C. SYKES & H. EVANS. *J. Iron Steel Inst.,* Advance Copy No. 15, Oct. 1938, 23 pp. Original research. Measurements of specific heat by a modified aneroid method in the range 80°-450° C. were made on a number of samples of commercially pure Fe and C steels. The results are in reasonable agreement with accepted values. No experimental evidence was found that confirmed the presence of the discontinuities reported by Naeser and Dearden. An examination of the published literature dealing with abnormalities in physical properties of Fe indicated that the indirect evidence which it brings to the support of the results of Naeser and Dearden is not strong. 55 references. JLG (10a)

Vanadium in Steel and Iron. W. J. PRIESTLEY (Electro Metallurgical Co.) *Metals and Alloys,* Vol. 9, Aug. 1938, pp. 193-197; Sept. 1938, pp. 237-241. A complete history of the discovery of V, the occurrence of the V-ores, its properties, effects in steel, uses and applications are well presented in this article. No important commercial use for pure V has been developed. This element is used in the non-ferrous field in an alloy of Cu and V for use in propellers for salt water. Ferro-V is the principal outlet for V at the present time. V is an excellent deoxidizer and degasifier of molten steel. V progressively increases the tensile strength and, more especially, the elastic limit of steel, until a V content of 1% is reached; above 1% V, these properties are not increased and may even be decreased. C-V steels are used in the railroad industry and also for small forgings, for heat treatment produces exceptional properties. Low C-V steel makes excellent welding rod for oxyacetylene welding. Low C-V steels, being easily heat-treated, are used for case-carburized parts that are subjected to wear involving high stresses. Medium C-V steels are employed for gears, axles and, in some cases, crankshafts, etc. High C-V steels are used for ball and roller bearings, wearing plates, dies, etc. Mn-V steels, Mn-Cr-V steels and special V-steels containing Cr, Ni, Mo and Mn are discussed; the Mn-Mo-V combination is adaptable to elevated temperature service, as it has a considerably lower creep rate than the well-known 18:8 Cr-Ni stainless steel. V is used in cast Fe. From 0.10 to 0.15% V in cast Fe increases the strength of the Fe from 10 to 25%, and adds a considerable amount of toughness as a direct result of the uniform grain size produced. Ni-V-cast irons possess good wear-resistance properties and are used for heavy forming dies. The addition of 0.75% Cr to the Ni-V-cast Fe gives a hard, wear-resisting alloy, applicable for dies and chilled rolls. It is possible to obtain 60,000 lbs./in.^{2} tensile in as-cast Fe of such a combination. V in combination with Ti prevents high-C high-Si irons from chilling rapidly, even in thin sections, and is used for the manufacture of piston rings. With the addition of 2% Cr to a V-cast Fe, a tensile strength of 75,000 lbs./in.^{2} can be obtained along with other favorable properties. CWH (10a)

Temperature-sensitive Magnetic Alloys and their Uses. L. R. JACKSON & H. W. RUSSELL (Battelle Mem. Inst.) *Instruments,* Vol. 11, Nov. 1938, pp. 280-282. Original research. The purpose of this investigation was to find the most suitable temperature-sensitive alloys that change their magnetic permeability over a sufficiently wide temperature range. A few devices where such alloys are applied in temperature-sensitive contactors, reactors and transformers are briefly described. A suitable alloy must not change its Curie point much with slight variations in composition; the Curie point should be independent of heat treatment and be the same for rising and falling temperatures. The permeability below the Curie point should be as high as possible and the alloy must be workable. Preliminary investigations on various alloy systems indicated that Fe-Ni-Cr-Si alloys satisfy the requirements most completely. Experimental data are graphically presented, showing the Curie points in relation to chemical composition (0-20% Cr), the magnetization values at 25° C. in a field of 30 oersteds (0-15% Cr), the temperature/magnetization of a 35% Ni, 5% Cr, 60% Fe + Si alloy and the room temperature/magnetization curves of a few typical Fe-Ni-Cr-Si alloys. The alloys were melted in a high-frequency induction furnace, cast into ½ in. bars of 8 in. length annealed at 1800° F. tested ballistically, hot rolled to ¼ in. diam. rod, annealed at 1800° F. and retested. The Curie point of a given Fe-Ni alloy is lowered by 1% Si as much as by 4% Cr. More than 1% Si harmfully affects workability; 2% Si introduces another phase with a higher Curie point in alloys containing less than 40% Ni. In the alloys reported, the Si content was constant at 0.3%.
EF (10a)

Mechanical Properties of Turbine Blades and Discs after Several Years' Successful Operation (Werkstoffeigenschaften langjährig bewährter Turbinenscheiben und -schaufeln) KARL DAEVES. *Wärme,* Vol. 61, Aug. 13, 1938, pp. 595-598. Original research. Wheel discs and blades of turbines that have operated satisfactorily since about 1916 were tested for chemical composition, microstructure, strength at elevated temperature, impact strength and other room temperature mechanical properties. Relatively high P and S contents, 0.005-0.008% and 0.04-0.07%, respectively, did not affect the service qualities. A few typical analyses show (a) 1-1.4% Mn, 0.3-0.4% C, (b) 0.5-0.8% Mn, 0.3-0.4% C, (c) 0.78% Cr, 1.9% Ni, 0.33% C. Considerable variations of impact strength were observed without any detrimental effect on service performance. Elongation values vary between 8% and 25%. Comparisons with modern specifications are made. There is no intimate relation between analysis and static tests (tensile, impact) on one hand and the service qualities on the other. It is, therefore, illogical to expect greater safety or better serviceability by making the specifications more severe. A greater uniformity of the physical properties is more desirable than unnecessarily severe specifications calling for more expensive materials.

The Timken Roller Bearing Company manufactured alloy steel for its own use in the production of TIMKEN Bearings a long time before TIMKEN Alloy Steel and TIMKEN Steel Tubing became available to other steel users. We started making our own steel because we wanted steel that would consistently meet the high quality standards demanded for TIMKEN Bearings. The steel we offer for sale today is made to the same quality standards, by the same methods and is subject to the same strict system of tests as the steel that goes into our own product. You could have no stronger assurance of its fitness for yours.

The Change of Young's Modulus of Elasticity by Magnetization of Iron and Carbon Steels. M. YAMAMOTO. *Nippon Kinzoku Gakkai-Si,* Vol. 2, Oct. 1938, pp. 495-502. In Japanese. Original research. The change of Young's modulus of elasticity by magnetization in annealed Armco Fe and various C steels, was measured by a magnetostrictive oscillation method. Young's modulus of elasticity in these materials increases by magnetization, and the amount of increase is of the order of 10^{-3}. The rate of increase is large in weak magnetic fields, and becomes gradually less as the field increases. For a given magnetic field, $\Delta E/E$ decreases continuously as C content increases. Every $\Delta E/E$ vs. intensity of magnetization curve consists of 3 stages. Akulov and Kondorsky's theory was confirmed for the total change of elasticity in Armco Fe. The initial susceptibility plays an important rôle in the change of Young's modulus of elasticity by magnetization in Fe and C steels. NS (10a)

Nickel-boron Cast Iron for Resistance to Abrasion. WALTER F. HIRSCH (Ind. Res. Labs., Ltd.) *Metal Progress,* Vol. 34, Sept. 1938, pp. 230-232, 278. Descriptive. The introduction of B into cast Fe caused a white fracture, even though a graphitizing element such as Ni was present. The resulting white Fe was considerably harder than ordinary white Fe, and also possessed exceptional abrasive resistance properties. When B is added to Fe-C alloys, it effectively prevents graphitization, unless the Si content is unduly high. As little as 0.25% B added to an ordinary gray Fe will render it white. B apparently enters into combination with the cementite and greatly increases its stability. With the addition of 4% Ni to such an Fe, the maximum hardness is obtained, as demonstrated by a comparative graph, and the air-cooled structure of martensite and cementite are well illustrated in 2 photomicrographs. The direct reduction of B from B compounds is recommended for the production of commercial alloys. The physical properties and applications of such Fe-B alloys are described. CWH (10a)

The Effect of Copper, Molybdenum, Tungsten, Titanium and Vanadium on the Magnetic Properties of Iron-nickel-aluminum Alloys. A. ZAIMOVSKII, P. DENISOV & N. VOLKENSHTEIN. *Stal,* Vol. 8, May 1938, pp. 60-64. In Russian. Original research. Cu, Mo, W, Ti and V were added to the extent of 3, 6 and 9% to an alloy containing 20-28% Ni, 9-15% Al and balance Fe. Cu increased the coercive force of 25-28% Ni and 13-15% Al alloy in the cast condition without decreasing the residual induction. Cu was not beneficial in alloys containing 11% Al, *i.e.* in those requiring quenching to develop maximum magnetic properties. Mo and W lowered both coercive force and residual induction. Ti and V increased coercive force and decreased residual induction a corresponding amount. HWR (10a)

Properties of Mild Steel Made of Sponge Iron. KAZUJI KUSAKA. *Tetsu-to-Hagane,* Vol. 24, Mar. 25, 1938, pp. 281-285. In Japanese. Experimental. Using sponge Fe industrially manufactured by a special rotary kiln from rich Fe ores produced in Manchukuo and China, mild steel (0.06-0.11% C) was made in a high frequency induction or in an electric arc furnace. Mechanical properties and weldability of this steel were tested and the following results obtained: Tensile strength, elongation and reduction of area of this mild steel were 1-7% higher than those of an ordinary mild steel. Impact resistance of the special steel, when the latter was cooled in a furnace from 900° C., was 3-7 times, and when quenched from the same temperature, was 1.7 times that of the ordinary steel. The weldability of the mild steel made of sponge Fe was better than that of an ordinary one. TS (10a)

Thermal Expansion of Nickel-iron Alloys (Nickel from 30 to 70 Per Cent) J. M. LOHR & CHARLES H. HOPKINS (Driver-Harris Co.) *Metals Tech.,* Vol. 5, Dec. 1938, T.P. 987, 7 pp. Original research. Expansion curves of 23 Ni-Fe alloys resulting from an effort to find satisfactory alloys for sealing into various types of glass, and containing from 30 to 70% Ni, were obtained. Special attention was given to alloys in the range 40 to 55% Ni. Over this range, observations were made on alloys of which the variations in Ni content were small. Heating and cooling curves are shown, and curves showing the effect of Ni content on both the inflection temperature and on the expansion up to the inflection temperature are given. JLG (10a)

Statistics of Rail Failures on German Railroads (Die Schienenbruch-Statistik der Deutschen Reichsbahn) V. HERWIG. *Stahl u. Eisen,* Vol. 58, Oct. 20, 1938, pp. 1129-1137. Practical. The familiar types of rail failures, such as transverse fissures, split heads, exfoliation of the heads, wheel burns, breaks due to segregation, rusting, cracks through the bolt holes for splice bars, etc., are described and the statistics on their incidence in the 5 years to 1937 given. The German railroads have kept records of these classified failures as related to the type of road and service, and to the grade of steel. It is hoped that these statistics will help reveal the causes of some of these failures and indicate how they may be avoided. SE (10a)

A. J. PHILLIPS, SECTION EDITOR

A Study of the Mechanical Properties of Tin-rich Antimony-tin Alloys. D. HANSON & W. T. PELL-WALPOLE (Univ. Birmingham) *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 810, 22 pp. Original research. Tensile and Brinell tests were made on alloys containing 2-18% Sb in the form of machined chill-cast specimens, rolled strip and extruded wire. Results are given graphically. In any condition, little improvement is obtained by using more than 9% Sb. The effect of progressive amounts of cold work on Brinell hardness was studied. Alloys containing 4.5-7% Sb can be permanently hardened by 10-30% reduction, but an alloy with 14% Sb cannot be permanently hardened even by small amounts of reduction, and severe cold working produces pronounced softening. Grain size may be an important factor in work softening and in subsequent recovery by annealing. Quenching from 225° C. produces a slight improvement in alloys containing more than 10% Sb, but has no effect on alloys with less Sb. Tempering at 100° C. after quenching from 215-240° C. causes softening in alloys containing more than 12% Sb, but the same treatment produces temper hardening in alloys containing 7-10% Sb, the maximum effect being obtained with 9% Sb. It is noted that grain size may have a marked influence on tensile strength of the alloys. JLG (10b)

Temperature Scale and Thermionic Emission from Rhodium. H. B. WAHLIN & L. V. WHITNEY (Univ. Wisconsin) *J. Phys. Chem.,* Vol. 6, Oct. 1938, pp. 594-597. Original research. When Rh is heated to incandescence in an atmosphere of O or air, a coating forms on its surface; this is shown by a change in the emissivity. When the temperature is increased sufficiently, this coating suddenly disappears and when the temperature is lowered, it reappears. This coating is probably an activated adsorption of O or an oxide of Rh. Experiments proved that the temperature and partial pressure of O at which the coating disappears are related by the Clausius-Clapeyron equation: $(d_{\cdot} \log_{\cdot} P)/dT = L/RT^2$, wherein P = partial pressure of O, T = absolute temperature and L = heat of vaporization of the surface. The work function of a clean Rh surface is found to be 4.80 electron-volts and Richardson's constant to be 33 amps./cm.^{2}/deg.^{2}. EF (10b)

Elastic Properties and Grain Size of Aluminum Wire. MIYABI SUGIHARA. *Mem. Coll. of Sci., Kyoto Imperial University,* Series A, Vol. 21, Sept. 1938, pp. 163-168. Research. In Al wire Young's modulus has the same value independent of the grain sizes. On the other hand, the elastic limit depends upon the grain size. This is probably because the elastic limit of the grain itself is greatly affected by its boundary, which is elastically stronger. Under such a consideration, the relation between the elastic limit and the grain size number may be expressed by a relatively simple formula. For previous work see also *Metals and Alloys,* Vol. 9, Jan. 1938, p. MA 44 R/1. HN (10b)

Magnetic Permeability of Nickel to Hertz Oscillations (Ueber die magnetische Permeabilität des Nickels für Hertzsche Schwingungen) KARL F. LINDMAN. *Z. tech. Physik,* Vol. 19, Oct. 1938, pp. 323-324. Original research. Employing the author's method described in *Z. tech. Physik,* Vol. 19, 1938, p. 159, and using 2 parallel Ni wires, 0.072 mm. dia., the magnetic permeability (μ) of Ni to Hertz oscillations of various wave length (λ_0) within the interval from 15.8 to 86.0 cm. was found to be as follows:

$\frac{1}{2}\lambda_0$ cm.	μ
7.9	3.1
13.0	6.3
18.0	13.0
24.2	18.4
43.0	19.9

ORS (10b)

Overhead Lines of Cadmium-copper (Les Conducteurs en Cadmium-Cuivre pour Lignes Électriques Aeriennes) G. W. PRESTON. *Cuivre et Laiton,* Vol. 11, Nov. 30, 1938, pp. 487-491. Review. Cd-Cu wires are used for telephone and telegraph lines; they contain 0.9% Cd, have an electric conductivity of 85% of that of Cu and a tensile strength of 100,000 lbs./in.^{2} For the larger conductors of overhead lines 0.8-1.0% Cd is added to Cu; the fatigue resistance is higher than for other materials with equally high conductivity. A table with comparative electrical and transmission line characteristics for hard-drawn Cu and for Al cable with steel core is added. Ha (10b)

Hydration by Colloidal Rhodium (Hydrierung durch kolloidales Rhodium) C. ZENGHELIS & K. STATHIS. *Sitzber. Akad. Wiss. Wien, Math. Naturw. Klasse, Abt. IIb, Chemie,* Vol. 147, No. 2, 1938, pp. 134-138. Original research. As a catalyst in hydration processes, colloidal Rh was found to yield the same results as colloidal Pt and Pd. Rh even furnished greater reaction speed. In some cases, Rh was suitable where Pt and Pd failed to operate. Rh is superior to all other metals of the Pt group as well as to Ni at ordinary temperatures. EF (10b)

The Elastic Properties of Some Anti-friction Alloys at Room and at Elevated Temperatures. J. W. CUTHBERTSON. *J. Inst. Metals,* Vol. 64, 1938, Advance Copy No. 818, 23 pp. Original research. A plane bending test with interferometer deflection-recording mechanism was adapted to the determination of the elastic moduli of cast Sn and a series of Sn-base alloys at room and ordinary temperatures. All of the materials examined creep under relatively low stresses, but obey Hooke's law if the load is applied with sufficient rapidity. A standard rate of loading was therefore adopted throughout. There is little difference between the elastic modulus-temperature curves of high-Sn alloys, although E tends to increase as the Sb content increases. Pb, even in small quantities, alters the shape of the curve and leads to failure by creep at or near the melting point of the Pb-Sn eutectic. Cd in amounts up to 1% has little effect. Above 50° C., and almost up to the melting point, the curve for Sn falls linearly, but less steeply than the curves for the Sn alloys, and intersects the latter near 210° C. The Pb-base alloys have lower elastic constants than the true Babbitts and, with the exception of Bahnmetal, fail by creep at or well below 180° C. An appendix contains the hardness values and Hargreaves flow indices for the alloys investigated. JLG (10b)

The Mg-Al_3Mg_4-Mg_5Tl_2 Region of the Ternary Magnesium-aluminum-thallium System (Der Teilbereich Mg-Al_3Mg_4-Mg_5Tl_2 des Dreistoffsystems Magnesium-Aluminium-Thallium) W. KÖSTER & E. WAGNER. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp.338-342. Experimental. The liquidus surface for the Mg corner of the Mg-Al-Tl system was determined by thermal analysis and microscopic observation. The ternary eutectic of the Mg, Al_3Mg_4 and Mg_5Tl_2 phases is at 395° C. and 32.5% Mg, 5% Al, 62.5% Tl. The limits of the ϵ phase, the Mg-rich solid solution, were determined by temperature-resistivity curves. At the eutectic temperature the Al content of the ϵ phase is 12.1, 11, 9 and 7% for 0, 10, 20, 30% Tl, respectively; while at room temperature the Al content varies from 2.5 to 1%. In the cast alloys, hardness was increased more by additions of Al than of Tl. Aging experiments showed the maximum hardness was obtained from an alloy of 71.8% Mg, 8% Al, 20% Tl, 0.2% Mn when annealed at 200° C. The resistance to atmospheric corrosion was increased by additions of Al. Corrosion resistance to distilled water was increased by Al additions within the ϵ solid solution range only. Aging at 250° C. produced the greatest corrosion in the 71.8% Mg, 8% Al, 20% Tl, 0.2% Mn alloy. GD (10b)

The Effect of Small Additions of Tellurium on the Mechanical Properties of Pure Tin. D. HANSON & W. T. PELL-WALPOLE. *J. Inst. Metals,* Vol. 63, 1938, Advance Copy No. 814, 14 pp. Original research. Sn-Te alloys with up to 1% Te were prepared by first making a temper alloy by adding Te to Sn under borax and adding the temper alloy to Sn under charcoal. Tensile, Brinell and creep tests were carried out on machined chill-cast specimens and on rolled strips of alloys containing up to 0.1% Te. The effects of cold rolling and various heat treatments were studied. Up to 1% Te slightly improved Brinell hardness and tensile strength of Sn, but heat treatment of alloys did not produce permanently improved properties. Te-Sn alloys had a remarkable capacity for work hardening in the chill-cast state, but this was diminished when the ingots were annealed before deformation. Te considerably improved the creep strength, both in the cast and rolled conditions. The work-hardening properties of these alloys may form a valuable guide to their relative creep strength. Grain-size measurements were made after various mechanical and thermal treatments, and it was found that grain size has a marked effect on creep strength of these alloys. JLG (10b)

The Magnetic Properties of Cobalt-manganese-aluminum Alloys (Die magnetischen Eigenschaften der Kobalt-Mangan-Aluminium-Legierungen) W. KÖSTER & E. GEBHARDT. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 286-90. Experimental. Measurements of the maximum magnetic moment were made throughout the α solid solution range in the Co-Mn-Al system, attaining a maximum of about 7,500 gauss. In general, the values are somewhat greater than for the same alloys containing Ni instead of Co. When a superstructure can exist, the Curie temperature is lowered as the degree of order increases in the solid solution alloys. Magnetic aging occurs in the α-γ, and to a less extent in the α-β Mn two-phase regions. GD (10b)

Tellurium Lead for Plating and Pickling Equipment. G. O. HIERS & G. A. STEERS. *Metal Ind., N. Y.,* Vol. 36, Dec. 1938, pp. 563-566. Practical. The addition of small amounts of Te to Pb gives increased fatigue resistance and resistance to corrosion. Te-Pb, when used in plating and pickling tanks, gives greater life than chemical Pb. Te-Pb has a finer structure and smoother surface, thus diminishing the possibility of pitting and local corrosion; resistance to corrosion fatigue is better. Stability of structure at elevated temperatures keeps down rapid corrosion. Te imparts work-hardening properties to Pb so that the alloy becomes strengthened when strained. This property is especially valuable for heating coils. CBJ (10b)

OFHC

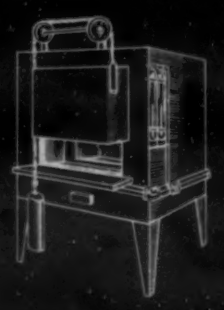
OXYGEN FREE HIGH CONDUCTIVITY

A Superior Copper

FOR ALL PURPOSES

OFHC Copper conforms to the A.S.T.M. Specification for electrolytic copper wirebars, cakes, etc., B5-27 with regard to metal content and resistivity, and is free from cuprous oxide.

OFHC Copper is characterized by its freedom from casting defects and its bar-for-bar uniformity. Its freedom from oxygen results in great ductility and toughness as evidenced by its high reduction of area and resistance to impact.



OFHC Copper withstands more working in hard condition when tensile strength is greatest, making it especially suited for products subjected to severe fabricating or service conditions.

Plastic Deformation of Lead, Copper and Aluminum under Static Compression. W. J. LYONS. *J. Applied Phys.*, Vol. 9, Oct. 1938, pp. 641-646. Experimental. A study was made of the effect of load duration in the plastic compression of small cylinders (usually 1.27 cm. height by 0.826 cm. diameter) of Pb, Cu and Al. This effect is important in the use of Pb "crushers" for measuring pressures. Static compression tests were made on Pb over 30-min. periods and under loads up to 109 kg. The time effect is greater at the higher loads and is greater for Pb than for Cu and Al. Under constant pressure the deformation-time relation is approximately linear. The data on Pb agree with results of Bogomolov and Kunin for pressures in the higher range, but an equation proposed by them does not hold in the lower range of pressures studied in this work. HFK (10b)

The Paramagnetism of Manganese (Sur la Paramagnétism du Manganese) A. SERRES. *J. Phys. Radium,* Vol. 9, Sept. 1938, pp. 377-380. Original research. Contradictions in previous literature are summarized. The experimenter employed vacuum-distilled Mn of 99.99% purity, the impurities being traces of Al, Fe, Co, Mg, Ag and P. Between —183° and +600° C. the paramagnetism of Mn varies with temperature only slightly and in a continuous manner. At low temperatures, the magnetization passes through a maximum. At elevated temperatures it seems to be directed towards a limit below 600° C. probably up to the temperature of the transformation of $\alpha \rightarrow \beta$. The anomaly in the specific heat found by Ashworth (*Proc. Roy. Soc.*, 1936, Vol. 48, p. 456) has no corresponding effect in the magnetization/temperature curve. EF (10b)

The Changes of the Modulus of Elasticity and the Damping Capacity during Deformation and Recrystallization of Brass (Die Änderung von Elastizitätsmodul und Dämpfung bei der Verformung und Rekristallisation von Messing) W. KÖSTER & K. ROSENTHAL. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 345-348. Experimental. Deformation of a 72% Cu, 28% Zn brass lowered the modulus of elasticity. The original value was recovered in 2 steps on annealing, the first third occurring below the recrystallization temperature, the remainder of the recovery accompanying recrystallization. The modulus continues to increase during grain growth. The damping capacity is increased by deformation and this can be attributed to internal stresses. It returns to the normal value rapidly at room temperature, although the process is accelerated by heating. Recrystallization gives rise to another increase in the damping capacity. GD (10b)

The Mg-$MgCd_2$-Mg_5Tl_2 Region of the Ternary System Mg-Cd-Tl (Der Teilbereich Mg-$MgCd_2$-Mg_5Tl_2 des Dreistoffsystems Magnesium-Kadmium-Thallium) W. KÖSTER & E. WAGNER. *Z. Metallkunde,* Vol. 30, Sept. 1938, pp. 335-338. Experimental. The liquidus surface of the region was explored by thermal analysis, showing one quaternary reaction: Melt + Mg solid solution $\epsilon \rightleftarrows MgCd_2 + Mg_5Tl_2$, at about 320°. The homogeneity range of the ϵ phase was determined microscopically and found to extend to an alloy containing 45% Cd and 15% Tl. The hardness of alloys annealed at 350° C. for 24 hrs. and then quenched increased regularly with alloy additions. An alloy containing 35% Cd and 35% Tl showed considerable increase in hardness after aging at 250° C. The density of the ϵ phase was decreased by alloy additions. The resistance to atmospheric corrosion is increased by addition of the alloying elements to Mg, but resistance to corrosion by conductivity water is decreased. GD (10b)

Embrittlement of Tin at Elevated Temperatures and its Relation to Impurities. C. E. HOMER & H PLUMMER (Internatl. Tin Res. & Development Council) *J. Inst. Metals,* Vol. 64, 1938, Advance Copy No. 820, 32 pp. Original research. A simple bending test with the Sn specimen in oil, and maintained at any desired temperature, was used for determining brittleness. The brittleness of Sn below its melting point resulted from impurities. Moreover, by carrying out the test on a series of alloys over a range of temperature, solidus curves of Sn-rich alloys could be determined. Curves for Sn with Pb, Cu, Bi, Cd, Zn and Ag were determined. Sb, As and Fe did not make Sn brittle below its melting point. The influence of 2 or more elements on brittleness was also studied. Previous literature on the supposed high-temperature form of Sn was reviewed, and it was concluded that there is no such modification. Where transformations at elevated temperatures were reported, these were probably caused by impurities and were not real allotropic transformations. JLG (10b)

10c. Effect of Temperature

H. C. CROSS, SECTION EDITOR

The abstracts in this section are prepared in cooperation with the Joint High Temperature Committee of the A.S.M.E. and the A.S.T.M. The purpose of this cooperation is to make readily available complete references to the literature of this subject. The Committee does not necessarily subscribe to the statements of either the author or the abstractor.

The Creep of Metals Under Static and Repeated Stresses. F. C. LEA. *Foundry Trade J.*, Vol. 59, Oct. 6, 1938, pp. 251-252. Creep occurs and may lead to fracture above 300° C. under static stresses much less than required for failure under rapid loading. For pressure vessels, the allowable rate of creep is obtained at a stress about ½ the tensile strength at 300° C. and at 500° C. at less than ⅓ the tensile strength. In designing equipment for high temperature service, the expected life and maximum allowable strain dictates the working stress. Structural stability as well as creep strength of the steels must be considered. Under repeated stress at elevated temperatures, a slow cycle such as 2 to 3 a minute produces creep similar to that under a steady load. Relative merits of steels for a new problem can be approximately obtained by short-time tests, but as yet no short-time test will indicate the final rate of creep to which after a certain time at a particular stress the metal will settle down. HCC + AIK (10c)

Growth of Cast Iron for Piston Rings at Temperatures up to 700° C. (Wachsen von Gusseisen für Kolbenringe bei Temperaturen bis 700°) F. BOLLENRATH & K. BUNGARDT. *Stahl u. Eisen,* Vol. 58, Oct. 13, 1938, pp. 1111-1113. Original research. The growth on prolonged heating of several piston ring cast irons of about 3.8% C, 3% Si, 0.8% Mn, 0.7-1% P, 0.1-0.5% Cr and 0.3-0.8% Mo was determined with a Leitz dilatometer. The rate of growth reaches a maximum after a certain time at temperature, this time being shorter for higher temperatures; with further heating the rate of growth then diminishes. At the low temperature of 450° C. observable increase in length was only noticed after 500 hrs. heating, and there was doubt whether this was really growth or drift in the measurement. The temperature range where growth began after a heating period of 700 hrs. was about 450° C. SE (10c)

Bi-metals for Temperature Controls. HOWARD D. MATTHEWS. *Elec. Mfg.*, Vol. 22, Sept. 1938, pp. 35-37. Review. For soldered bi-metals, the maximum usable temperature is 600° F. Welded bi-metal strips are designed for use above this temperature. Steel alloys with Cr, Ni and Mn give maximum expansion through a specific temperature range and may be utilized up to 1200° F. In general, a 40-50% Ni steel is used on the low expansion side above 500° F. For maximum sensitivity, there has been little improvement over the invar-brass combination. Author gives a number of useful formulas. FHC (10c)

V. V. KENDALL, SECTION EDITOR

Structure of Iron Oxides Obtained at Moderate Temperatures M. S. BORUSHKO & N. F. LASHKO. *Zhur. fiz. khim.*, Vol. 11, May 1938, pp. 737-743. In Russian. Original research. The oxidation products of 7 varieties of iron and steel subjected to corrosion or severe plastic deformation in various media, were analyzed by the Debye-Scherrer-Hall X-ray method in a pin-hole camera using Fe and Cu radiation. The oxidation products were analyzed on the samples themselves or in the form of powder scraped from their surface. Materials tested included Armco Fe, boiler plate, 0.8% Cu steel plate, Cr-Cu steel, and rail steel. The media were sea water, river water, flue gases, air, caustic soda and nitric acid solutions. Both the medium and material were usually changed with each test, so that conclusions as to relative corrodibility cannot be drawn. The predominant constituent of the oxides obtained at room temperature was a ferromagnetic Fe oxide, the X-ray data pointing to γ Fe_2O_3 rather than Fe_3O_4. With Armco Fe in flue gases only paramagnetic α Fe_2O_3 was formed, it is possible that ferromagnetic γ Fe_2O_3 was formed primarily, which, being unstable at the higher temperatures of the test (210° to 275° C.), secondarily transformed into the paramagnetic modification. The absence of oxidation products on the Cu-steel plate exposed to caustic soda solution is probably due to the formation of a thin protective film by the action of the NaOH solution. The surface of the rail steel was crushed by rolling 2 cylindrical specimens over each other in the Amsler machine. Blue scales formed and were found to contain a greater proportion of α Fe_2O_3, a smaller amount of γ Fe_2O_3, and no FeO. A small amount of crystalline hydroxides was also present, their crystallites being larger than those of γ Fe_2O_3. In scraping the oxide powder from the deformed specimens, particles of metallic Fe were apparently also removed, whose high-index interference lines seemed to be more intensive than the low-index ones. This fact possibly indicates the presence of stresses of a third kind—stresses determined from the relation between the intensities of different-indexed lines which are connected with the deformation of the crystal lattice. The interference lines of the oxides and hydroxides exhibited no anomalies, so that their crystal lattice may be assumed to have undergone no perceptible deformation. ORS (11)

Corrosion and Erosion in River and Harbor Structures. FRED DIEFFENBACH (U. S. War Dept.) *Ind. Eng. Chem.*, Ind. Ed., Vol. 30, Sept. 1938, pp. 1014-1020. Practical investigation. Very severe corrosion-erosion conditions exist in the Monongahela River as the result of highly acid sand-bearing water. The condition is best corrected in most cases by use of corrosion-resisting materials, such as fortified paints or enamels, corrosion-resisting iron alloys, alloy cast irons, Ni-Cu alloy (Monel), etc. Detailed specifications are given for a superior corrosion-erosion resisting paint for Fe and steel structures in the River. An austenitic 2-4% Mo, 16-20% Cr, 7-14% Ni steel, which is not only corrosion resistant but resists erosion because of its work hardenability is recommended for steel structures for this service; a Mo-bearing, 0.12% C, 12-15% Cr steel may be used where the uniform high hardness available by heat treatment is desired. For bearings lubricated only by the river water a bronze containing 80% Cu, 10% Sn, 10% Pb and 0.30-0.50% P has given good results. A good boiler compound for treating river water for boiler use contains 61% sodium carbonate, 18% sodium phosphate monohydrate, 13% sodium hydroxide and 8% tannates. Method and equipment for making accelerated tests on materials are included. MEH (11)

Relation of Soil Properties to Corrosion of Buried Steel. WALTER F. ROGERS (Gulf Oil Corp.) *Ind. Eng. Chem.*, Vol. 30, Oct. 1938, pp. 1181-1188. Research. Studies were made on the relation of soil volume-water content, soil pH, and soil electrical resistivity to the corrosion of buried steel pipe. The importance of these factors are shown in data developed from actual tests in the laboratory and in the field. While both the electrical resistivity and soil pH have some effect on the soil corrosion rate, the governing factor is the soil volume-water content. 16 references. MEH (11)

3 **Anodic and Ordinary Corrosion of Ferrous Metals in Various Acids.** RAYMOND R. ROGERS & EDGAR BLOOM, JR. (Columbia Univ.) *Trans. Electrochem. Soc.*, Vol. 74, 1938, Preprint No. 22, 11 pp. Original research. The corrosion of the following metals was determined in 3-12 *N.* solutions of HCl, H_2SO_4, HNO_3 and H_3PO_4, at room temperature and at 60° C.: Cold rolled steel; 18-8 Cr-Ni steel; 14% Cr iron; Silcrome RA (16% Cr, 1.25% Cu, 1.25% Si); Duriron (14.5% Si, 0.8% C, 0.35% Mn); and Durichlor (14.5% Si, 3% Mo). Most of the test specimens were sheet metal 2 in. x 1 in. The rate of corrosion was expressed as the loss of weight of a specimen in mg./min. 2 corrosion rates were measured: (1) The test specimen was simply immersed in the corroding solution; (2) the specimen was made anodic with a current density of 0.5 amp./in.^{2} Duriron and Durichlor were corroded in HCl, H_2SO_4, and HNO_3 less than the other metals, but were corroded more in H_3PO_4. The 14% Cr iron was corroded the most rapidly of the metals in HCl and H_2SO_4. With the exception of steel, all the metals resisted attack by HNO_3 on simple immersion, but all metals were attacked by anodic corrosion. Durichlor was slightly more resistant than Duriron to corrosion on simple immersion, but was slightly less resistant to corrosion on anodic treatment. AB (11)

5 **Hydrofluoric-acid Corrosion; Where Monel Metal Has Proved Its Value.** *Chem. Trade J.*, Vol. 103, Nov. 4, 1938, p. 416. Descriptive. Outstanding use of Monel metal in contact with HF is for tanks and trays for etching and frosting glassware. Tests in a storage tank holding 40-60% HF at 20°-25° C. showed corrosion rate of 0.003 in. penetration/yr. continuous exposure. In 48% acid at 80° C., rate was 0.015 in./yr. exposed for 8 hrs./day, 365 days/yr. In 40% acid at 55° C., rate was 0.009 in./yr. continuous exposure. A tank has been in service holding concentrated HF stock etching solution for 15 yrs. with no signs of destructive attack. Specimens exposed in a duct carrying away HF fumes showed corrosion rates of 0.00002-0.00003 in./yr. continuous exposure. Cups handling paste of 100 oz. HF, 99 oz. (NH_4) HF_2, 66 oz. $(NH_4)_2$ CO_3, and 21 oz. NH_4Cl showed rate of 0.008-0.009 in./yr. continuous use. Monel metal is successfully used for equipment for pickling cast-Fe with HF. Tests in a 6% solution at 80° C., showed corrosion rate of 0.0006 in./yr. continuous exposure. In 10% acid at 10°-20° C., rate was 0.000002 in./yr continuous exposure. In this test, cast-Fe rate was nearly ¼ in./yr. Monel metal equipment is used in laundries for acid fluoride sours with no evidence of attack. It is also used in electrolytic refining of Pb, where H_2SiF_6 is the important corrosive. MS (11)

8 **The Tarnishing of Silver and Silver Alloys and Its Prevention.** L. E. PRICE & G. J. THOMAS. *J. Inst. Metals*, Vol. 63, 1938, Advance Copy No. 812, 29 pp. Original research. Seventy thousand specimens of pure Ag and of 100 of its alloys were exposed for periods up to 1 yr. in 15 different locations, mainly in living rooms and kitchens. The tarnishing of these specimens was followed by observation of the tarnish colors produced, and by an electrometric method. A theory was developed that showed the factors involved in tarnish resistance. It explains many results and has indicated that other alloys *(e.g.* those containing Al) which have not previously been found to be tarnish-resistant, become tarnish resistant when the alloy is heated under conditions that only the Al is oxidized, giving rise to an invisible film of pure Al_2O_3. Tarnish-resistant films cannot be formed by heating these alloys in air, owing to the fact that both Ag and its alloy constituents oxidize simultaneously. Optimum results can be expected only with pure films of such oxides as Al_2O_3 and Be_2O_3 when free from Ag oxide. Two methods were developed for the formation of such films: (1) Selective oxidation of Al or Be in Ag-base alloys by heating in H containing 0.1 mm. partial pressure of H_2O, to give a film of pure alumina or beryllia, and (2) superimposing transparent, cathodically-deposited films of these oxides on pure Ag and its alloys. Such oxide films are found to be highly protective against tarnishing. JLG (11)

The Attack of Hot Gases on Steel. E. HOUDREMONT & G. BANDEL. *Foundry Trade J.*, Vol. 59, 1938, Sept. 15, pp. 195-196; Sept. 22, 1938, pp. 220, 222. Review. So far as scaling is concerned, the principal alloying elements in steel may be divided into 2 groups: Those with a greater and those with a lower affinity for O_2 than has Fe itself. To the former group belong Al, Si, Cr, Mn, Zr, Ti, V and N, and to the latter Cu, Ni, Mo and Co. High scaling resistance depends on the formation of an oxide film denser than the coating formed on Fe alone, and which will be adherent and will impede the further progress of scaling; a self-healing film is ideal. Very important also are the impedance offered to the diffusion of O_2 or other active gas toward the underlying metal on one hand, and a similar impedance to the outward diffusion of the alloy through the oxide on the other. These factors are related, as is the sintering temperature of the oxide film, to the melting point of the oxide or silicate formed and to the melting point of the most fusible constituent of the scale. In addition to Al and Si as useful additions to Cr steels, Ni is also used to a very large extent; Ni improves the scaling properties of pure Fe only very slightly, but results in a great improvement when it is associated with Cr. In recent German installations a steel with about 0.9% Cr, 0.5% Mo, and 0.5% Si has been successfully used. The disparity between the rates of scaling in air and steam is difficult to explain; a more porous scale is formed when steam is the attacking atmosphere. It is possible that H_2 is liberated explosively and may render the scale porous or alter its chemical composition in some way. The alloying elements giving the greatest protection in air also increase the resistance to attack by sulphur dioxide. Scaling properties are related to the metallurgical history of the steel. Because all the heat-resisting steels contain elements with a great affinity for O_2, the danger is always present that these elements oxidize partially in the manufacturing process and may give rise to oxide segregation.

The Electrode Potentials of Metals and Alloys in Copper Nitrate Solution. YOICHI YAMAMOTO. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, *Abstract Suppl.*, pp. 37-38. In English. Original research. The single electrode potentials of 21 pure metals, 2 non-metals and 6 alloys in $Cu(NO_3)_2$ solution of 2-20% were determined by the valve potentiometer after 20 min. immersion. The results obtained in the weakest and strongest solution tested were as follows: *In 2% $Cu(NO_3)_2$:* Mg → Zn → Mn → Cd → Pb → Sn → Fe → Co → high C steel → Al → Sb → Bi → Si → brass → Cu → 80/20 Ni-Cr → Monel metal → Ni → Mo → W → 13% Cr stainless steel → 18/8 → Ta → Au → Ag → Cr → Hg → C → Pt. *In the 20% $Cu(NO_3)_2$ solution:* Mg → Zn → Mn → Cd → Sn → Pb → Al → Co → high C steel → Fe → Bi → Sb → brass → Cu → Monel metal → Ni → Mo → Si →Ta → 18/8 → 13% Cr stainless steel → 80/20 Ni-Cr → Ag → Hg → Cr → Au → W → Pt → C. The deposition of black compounds of Cu was observed on the surface of Mg, Zn, Cd (only below 8% $Cu(NO_3)_2$), Pb (only at 2% $Cu(NO_3)_2$), and the deposition of metallic Cu occurred on the surface of Cd (above 14% $Cu(NO_3)_2$), Pb (above 8% $Cu(NO_3)_2$), Fe, Co, Sb and Bi (above 14% $Cu(NO_3)_2$). Sn was attacked by copper nitrate solution, but Cu was not deposited; a white substance was formed on the surface. The other metals and alloys were scarcely attacked after 20 min. immersion.

The Phenomena of Abnormal Corrosion in Condenser Tubes. Part II. KURAZO FUKAGAWA & KEN-ITIRO KAMIYAMA. *Sci. Papers Inst. Phys. Chem. Research, Tokyo,* Vol. 34, Oct. 1938, pp. 1377-1408. In English. Original research. The following 2 types of abnormal corrosion in condenser tubes were studied: (a) The inlet and outlet portions are more vigorously corroded and eroded than the other portions, (b) the upper wall surface is more severely corroded than the lower wall surface. Tubes of various commercial condenser tube materials (analyses not given) were studied at 27° C., the flowing solution having the critical speed of 200 cm./sec. After 278-1079 hrs., the tubes showed the above types of attack. The majority of the tubes were made of Al-brass, which shows great differences in corrosion resistance, but were superior to Cu-Ni. 19 photographs. For previous work, see also *Metals and Alloys,* Vol. 7, Sept. 1936, p. MA 469 R/4; Vol. 8, Jan. 1937, p. MA 42 R/8.

Absorption of Hydrochloric Acid Gas with Tantalum Equipment. F. L. HUNTER (Fansteel Metallurgical Corp.) *Ind. Eng. Chem.*, Vol. 30, Nov. 1938, pp. 1214-1219. Descriptive. Pure Ta is completely inert to action of HCl up to 630° F. Besides being corrosion-proof, Ta has high thermal conductivity, and, with HCl, has remarkably good heat-transfer characteristics. Because of the high cost of the metal, the new unit for absorption departs from conventional design and makes the advantages of an acid-inert system available at a cost comparable with, or less than, the installation cost of conventional systems. Diagrams for the absorption system are given.

Research on Thin Layers of Tin and other Metals. V. The Corrosion of Tin by Dilute Organic Acids. J. A. NINCK-BLOCK-KITS VAN HEYNINGEN & D. A. WAS. *Proc. Koninkl. Akad. Wetenschappen Amsterdam,* Vol. 4, Sept. 1938, pp. 717-724. In English. Original research. Continuation of previous work. (For parts I, II, III and IV, see also *Metals and Alloys,* Vol. 9, Aug. 1938, p. MA 515 L/7.) Thin layers of Sn made on glass by high vacuum evaporation were exposed to weak solutions of citric, lactic, benzoic and propionic acids at room temperature. The corrosive effects were studied by an optical method (See part II). The quantities of dissolved metal in 10^{-6} g./cm.^{2} are plotted against time in min. for various concentrations. The character of the curves is essentially the same as that previously found for corrosion by oils. After some time, the first violent attack is retarded by the formation of a film of reaction products, which decreases the diffusion of the acid towards the metal surface. Nearly constant corrosion velocities were found for high concentrations. After some time, a stationary state is reached in all cases. The sequence of the corrosion attack is: Citric, lactic, propionic and benzoic acids. This falls in line with the relative values of the dissociation constants of these acids.
EF (11)

The Durability of Cast Iron Tanks for the Chemical Industry (Ueber die Haltbarkeit gusseiserner Kessel für die chemische industrie) A. GEISSEL. *Giesserei,* Vol. 25, Nov. 4, 1938, pp. 564-566. The composition of acid- and alkali-resisting cast Fe is discussed, and the factors determining the attack are explained. Alkali-resisting cast fe has preferably 3.3-3.5% C, 1.2-1.4% Si, 0.3-0.4% Mn, not over 0.3% P and not over 0.08% S; the lower Mn the better, as high Mn iron often gives a brownish color to the liquids in the tank. A correct ratio of graphite to combined C is important for the life of the casting. The higher the combined C the longer the life; a few tables of practical cases are given to illustrate this point.
Ha (11)

Metals in Wine-making (Die Metalle in der Weinbereitung) R. W. MÜLLER. *Korrosion u. Metallschutz,* Vol. 14, Dec. 1938, pp. 385-388. Experimental. The effect of metals on color, taste and aroma of wines and the corrosive effect of wines on metals were investigated, as replacement of the usually-employed wooden equipment by metal would save space and maintenance (leakages). Of the metals tested, Inconel and 18/8 steel were practically unattacked. The 18/8 steel, however, should not be used for closed fermentation tanks and mixers. Ni can be used for pipe lines, bottle-filling tanks, mixers and grape-juice containers, and also for open fermentation tanks. Monel metal and Cu should be used only for equipment in which the liquid does not remain long. Sn is the least suitable metal for wine cellar equipment; it is most strongly corroded in contact with red-wines. Pure Fe or steel can not be employed. The max. metal contents in wine if color, taste and aroma are to be unaffected, are: Fe, 1; Sn, 1; Cr, 15; Cu, 60; Al, 100; Zn, 200; and Ni, 200 mg./l. Solubility tables are given.
Ha (11)

Oxidation of Cu Alloys at High Temperatures. HIDEO NISHIMURA. *Suiyokwai-Shi,* Vol. 9, Oct. 1938, pp. 655-664. In Japanese. Original research. Cu alloys containing Al, As, Mn, Ni, Si, Sn and Zn in the α range were heated in an oxidizing atmosphere at 700°. The alloys containing more than 3% Al were the most resistant to oxidation at the higher temperatures, probably because of the formation of a compact surface film of Al_2O_3. The effects of As, Cr, Fe, Mn, Ni and Ti on the oxidation of the Cu alloys containing 8% and 10% Al were studied. The addition of Fe, As, or Ni was not harmful to the oxidation resistance of such Cu-Al alloys, but Mn and Si show a tendency to increase the oxidation. Addition of Cr is without effect on oxidation resistance, although the alloy is prone to much segregation.
HN (11)

Atmospheric Oxidation of Amalgamated Aluminum (Ueber die Quecksilberanfälligkeit des Aluminiums) H. LICHTENBERG. *Z. anorg. allgem. Chem.,* Vol. 239, Sept. 3, 1938, pp. 189-196. Research. The rate of reaction of amalgamated Al with air obeys the equation $G_1 = k\sqrt{t}$, where G_1 is the gain of weight in air of the activated Al, k a constant and t the time. A relation was noted between k and the purity of the Al. With increasing content of Cu, Fe and Si in Al, the rate of oxidation of the activated metal decreases.
HFK (11)

Dissolution of Aluminum in Pure Soda Solutions, and in those Containing Silicates (Die Auflösung von Aluminium in reinen und in mit Wasserglass versetzten Sodalösungen) H. LICHTENBERG & K. GEIER. *Korrosion u. Metallschutz,* Vol. 14, Oct./Nov. 1938, pp. 365-367. Research. The dissolution of pure Al sheets in soda solutions depends on the concentration of the attacking solution; even weak solutions attack strongly because of their high OH-ion concentration. The velocity of dissolution decreases with increasing length of time of the tests; this is explained by the formation of protective layers. An addition of 0.025% SiO_2 in the form of sodium silicate protects Al from dissolving in soda solutions.
Ha (11)

Some Observations on the Passivity of Stainless Steels. J. N. OSTROFSKY (Rustless Iron & Steel Corp.) *Am. Soc. Metals,* Preprint No. 8, 1938, 8 pp. Research. Treatment of stainless steels with warm 20-40% nitric acid for 1 hr. or more as a final processing step has long been practiced in order to remove surface contamination and promote formation of a surface conditions or passivity which serves to retard corrosion. Experiments indicate that treatment of stainless steels (0.10% C, 15-17% Cr) with boiling 0.1-0.5% nitric acid subsequent to pickling in the 20-40% acid produces a more durable passivity in the following solutions: (1) boiling 4% acetic acid containing 1% sodium chloride, (2) boiling solution containing 3 parts sulphuric and 1 part nitric acid diluted to a total acidity of 0.5% figured as sulphuric acid, (3) 25% by weight sulphuric acid. The weak nitric acid solution readily attacks steels having 13% or less Cr. These steels may be passivated with good results by treatment with a boiling solution containing 0.50% nitric acid and 0.50% potassium dichromate. Passivity to a 4% salt spray was most effective when developed by boiling in 0.50-5% dichromate solution. Good adherence of Zn and Cu plates on stainless steel was obtained by cleansing and activating in nitric-hydrofluoric acid mixtures. HLW (11)

Contribution to the Theory of the Tarnishing Process. III (Beitrag zur Theorie des Anlaufvorganges. III) CARL WAGNER & KARL GRÜNEWALD. *Z. physik. Chem.,* Abt. B, Vol. 40, Aug. 1938, pp. 455-475. Original research. Continuing the research on the mechanism of surface oxidation of heavy metals *(Metals and Alloys,* Vol. 5, Jan. 1934, p. MA 5; *Z. physik Chem.,* Abt. B, Vol. 32, 1936, p. 447), the rate of oxidation of Zn, Cu, Ni and of Ni-Au alloys with 0, 25, 50, 75 and 100 atomic % Au, as depending on the O_2 pressure, was determined. Rods or strips were kept from one to several days in a slow current of pure O_2 or of N_2 with 2.19% O_2, at 5-400° C. The rate of oxidation was measured by the increase in weight of the specimens. The rate of oxidation of Zn to ZnO does not depend on the O_2 pressure. The rate of oxidation of Cu to Cu_2O increases with the O_2 pressure. The rate of oxidation of Ni to NiO increases with the O_2 pressure. A graphic method for separate determination of the rates of the phase-boundary reactions and the diffusion processes is described. The rate of oxidation of some Ni-Au alloys is considerably greater than that of pure Ni. It must be assumed that the scale formed on these alloys is not completely sound, so that some diffusion of O_2 molecules through the pores can take place. ORS (11)

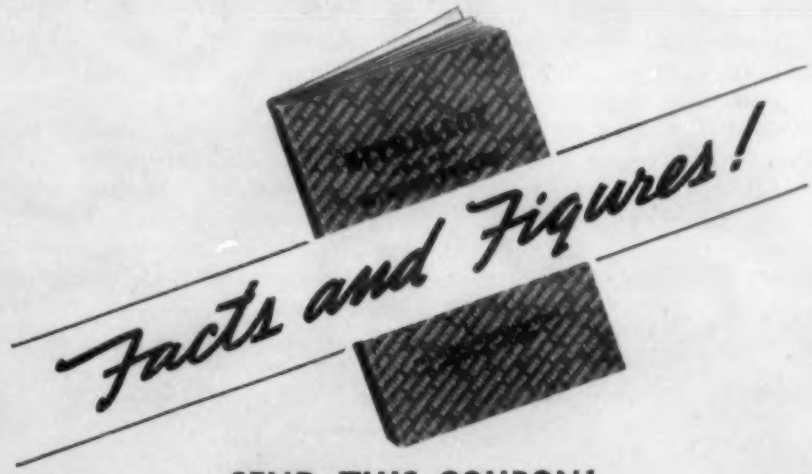
Black **Stain on Aluminum.** *Light Metals,* Vol. 1, Dec. 1938, p. 381. Discussion. The recent German paper on black stains on Al (see *Metals and Alloys,* Vol. 9, Dec. 1938, p. 737 R/9) is discussed with particular reference to the optics involved. Finely divided metal is a very poor reflector of light, especially when the particle size of the powder approaches the wave length of the incident light. Hence, if a layer of essentially colloidal Al is formed on Al kitchen utensils owing to the action of hot tap water, blackening may be accounted for on this basis. Another and alternative theory, advocated by the present author, assumes that the "Beilby layer" of the polished utensils is partially removed by the mild corroding media, thus exposing the underlying crystalline metal and causing a roughened surface. AUS (11)

The **Mechanism of Corrosion for Hydrogen-displacing Metals** (Mechanismus der Korrosion wasserzersetzender Metalle) E. PLANK & A. URMANCZY. *Z. anorg. allgem. Chem.,* Vol. 238, June 24, 1938, pp. 51-64. Corrosion theory and experimental data. The speeds of solution of Tl in HCl, HNO_3 and H_2SO_4 solutions of various concentrations were measured and used to test Urmanczy's theory of corrosion based on the Nernst and Brunner theory of diffusion. The theory predicts those acid concentrations at which the speed of solution of the metal will be a maximum. These were found to be in good agreement with experimentally determined values. The effect of speed of rotation on the corrosion of Tl disks was studied. See also *Metals and Alloys,* Vol. 9, Dec. 1938, p. MA 737 R/1. HFK (11)

Corrosion and Formation of Protective Layers by Water Flowing in Pipes (Korrosion und Schutzschichtbildung durch Leitungswasser) J. KOOIJMANS. *Gas- u. Wasserfach,* Vol. 81, Aug. 20, 1938, pp. 611-615; Aug. 27, 1938, pp. 628-633. The content of C, CO_2 and bicarbonates in water determines the rate of corrosion in Fe water pipes. Experiments to find the conditions of forming a protective layer with different temperatures and compositions of water are described in detail. The Ca-CO_3 equilibrium, which prevents corrosion, is disturbed by the organic substances always present in water. The rust-protective layer formed by lime consists of a crystalline precipitate $CaCO_3$ and $Fe(OH)_2$; the amount of Ca is about 1/10 that of Fe. $CaCO_3$ is precipitated by the discharge of H-ions; this gradually increases the alkalinity of the water which, in turn, increases the solubility of Fe, especially in soft waters. The mechanism of, and the chemical reactions leading to, the formation of the protective layer are explained in full. 9 references. Ha (11)

℞ for Maximum WEAR RESISTANCE

USE NITRALLOY



The Hardest Known Steel Surface

Where hard, wear-resisting surfaces are required, surfaces that retain their super-hardness indefinitely at temperatures up to 1000° F., try NITRALLOY. Many of the most difficult problems in this category are regularly being solved by this hardest of all steel surfaces.

The following companies, licensed manufacturers of NITRALLOY, will be glad to supply your needs, and offer you complete engineering services with regard to your steel problems:

Allegheny Ludlum Steel Corp., Watervliet, N. Y.
Bethlehem Steel Corp., Bethlehem, Pa.
Crucible Steel Co. of America, New York, N. Y.
Firth-Sterling Steel Co., McKeesport, Pa.
Republic Steel Corp., Massillon, Ohio
The Timken Roller Bearing Co., Canton, O.
Vanadium-Alloys Steel Co., Pittsburgh, Pa.

For detailed information on NITRALLOY and the nitriding process, send for the interesting booklet offered below.

SEND THIS COUPON!

The Nitralloy Corporation
Department MA4
230 Park Avenue, New York, N. Y.

Please send me a copy of your booklet on NITRALLOY and the nitriding process.

Dust Removal and Ventilation Problems in Industry

(Entstaubungs-und Lüftungsfragen in der Werkstatt)

Roland Nagel

VDI-Verlag, Berlin, 1938. Paper, 5¾ x 8¼ in., 42 pages. Price 2 RM.

This little book is evidently intended to inspire the industrial superintendent to transform his factory into a dust-free, well-aired workshop of the "model plant" variety. In his preface and throughout the book the author persistently stresses one general thesis, with which we are in full accord, and which industry may some day need no pressing to accept: Dust removal and adequate ventilation are not only essential in certain work from the humane or social viewpoint, but they pay real dividends in more efficient production, better quality of product, lower compensation and lost time charges, reduced explosion hazards and therefore lower insurance rates, decreased janitoring waste, or—most important of all to certain industries—the recovery of valuable material that can be re-used or sold as a by-product.

The general phases of the subject—types of processes, equipment and applications—are treated in this book, and no attempt is made to cover the details of exhaust and ventilating system design. A very large number of the existing and potential applications of air-cleaning and dust-removal systems are in the metallurgical industries, as is shown by examining the illustrations that make up a 14-page appendix to the book. Applications are illustrated for metal grinding and polishing, painting and lacquering, sandblasting, pickling and tin-melting, and many others are discussed in the text. It is, on the whole, an interesting little book that may offer to the metallurgical engineer in charge of plant operations a few new ideas for applying dust-removal and ventilation systems.—FRED P. PETERS.

Metallographic Atlas

(Atlas Metallographicus) Volume 2, Parts 5 and 6

H. Hanemann and A. Schrader

Gebrüder Borntraeger Verlagsbuchhandlung, Berlin, 1939. Paper, 7¾ x 11¼ in., 112 pages. Price 18.25 RM.

The structure of cast iron and the corresponding properties are illustrated and discussed in respect to composition and section, with attention also given to piston rings and centrifugal pipe. Chilled edges are also discussed.

The micrographs, as in the parts previously issued, are superb. The structures selected are so varied that one may usually be found that will closely resemble most of the specimens the metallographer has to deal with. It would often suffice for one's own records to note that a structure is as shown in a certain micro in *Atlas Metallographicus.*

Very little knowledge of German is needed to use the Atlas, as it consists primarily of the micros and tables describing them, so that this is more useful to the average American metallurgical engineer than the general run of German publications.—H. W. GILLETT.

Soil Corrosion and Pipe Line Protection

Scott Ewing

American Gas Assoc., New York, 1938. Cloth, 6¼ x 9½ in., 277 pages. Price $2.50.

The soil corrosion work that has been carried on cooperatively for many years by the Bureau of Standards, the American Gas Association, and the American Petroleum Institute has been covered by a multitude of progress reports. The owners of pipe lines and the producers of pipe have kept abreast of these reports as they came out, but even they, as well as those with less knowledge of the progress reports, will appreciate this summary, written by one who has been intimately connected with the work, in which the conclusions that the work has long pointed to, are rather definitely phrased.

Not only the technical matters, details of the extensive tests, laboratory methods for evaluating soil corrosiveness and field methods for mapping soil types and evaluating the condition of pipe lines, but also the economics of bare versus protected pipe and the engineering methods for coating pipe at the mill and in the field, and for protection by applied voltage, and by zinc anodes, are concisely dealt with.

On the whole, the soil is more of a variable than the pipe. Some soils are so innocuous that there is no need for protection, others so corrosive that it pays to take extreme precautions, but it doesn't make a whole lot of difference what ferrous material the pipe is made of; broadly speaking, they act much alike when buried in the same soil.

From a fine-haired viewpoint, the greater wall thickness of cast iron pipe plus the ability of cast iron to build up a tight crust even though corroded gives cast iron a long life for lines where the pressure is not too high. That wrought iron sometimes gives a somewhat better account of itself than would be expected from the broad statement that all ferrous materials act alike is explained on the basis that in these cases the soil is such that it discriminates between low and high phosphorus, and that the high P in the ferrite, not the slag, is the beneficial agent. In distinction to atmospheric corrosion, where the Cu + P combination shines, the Cu content makes little difference in soils.

Peculiarities in the behavior of replacement pipe, especially in service lines into houses, are ascribed to the fact that when a new pipe is connected into an old line, the new pipe usually becomes anodic and protects the old at its own expense. City soils are more variable and their behavior less predictable than soils not made by filling because the city streets are made up of everything "from bottles to bed springs."

Ordinary paints and thin bituminous coatings are useless, as they have pinholes and don't prevent pitting; a coating has to be uniform. Thick, perfect, wrapped, or otherwise reinforced, asphalt coats are useful, and concrete coats are good where the soil is low in soluble salts, but such coatings have to be applied by proper methods. Electrolytic protection, by applying current through copper oxide rectifiers, from wind-driven generators, or by zinc anodes connected in at frequent intervals, is called for in bad soils. Choice of pipe coatings or of no coating will depend on whether the coating alone is relied upon or whether electrolytic protection is to be applied.

The progress reports have been prepared with a lot of ifs and ands. This summary, while discussing variables and their effect in modifying general statements, does make positive and definite statements that have direct applicability to the metallurgical and engineering problems involved.—H. W. GILLETT.

Practical Methods of Material Testing

(Werkstoffprüfung)

Fredo Grahl

Carl Hanser Verlag, Munich, 1938. Paper, 6 x 8¼ in., 79 pages. Price 1.50 RM.

This pamphlet, No. 6 in the "Werkstattkniffe" series, starts with the usual description of specimens and methods for tensile testing, followed by compression, transverse, shear, torsion, notched impact, and hardness tests. Technical bend tests, those for strength of welds, repeated bend, Erichsen and wedge drawing tests are then described. Spark testing is illustrated by a score of photos. Deep etching and evaluation of a few plated coatings complete the topics.

The material is available elsewhere, but this is a convenient compilation. It deals almost solely with metals.—H. W. GILLETT.

Design of Industrial Exhaust Systems

John L. Alden

Industrial Press, New York, 1939. Cloth, 5¾ x 8¾ in., 220 pages. Price $3.00.

In the preface, the author states, "Industry . . . is well informed of the need for exhaust sanitation. It is not well informed as to how best to satisfy that need. The purpose of this book is to tell the engineer how to design and build or how to buy an exhaust system that will adequately and economically perform the functions prescribed by the industrial hygiene expert or by law." This purpose is filled by confining the discussion to the flow of fluids through hoods, pipes, and dust separators with only a short chapter devoted to exhaust fans.

Chapter I on the flow of fluids presents clearly and concisely the fundamentals of the subject. The use of nomograms is introduced here and continued throughout the book. In Chapter II on hood-forms the importance of their design is stressed by showing velocity contours and flow directional lines about the face of typical hoods. Examples of proper types of hoods for various kinds of machinery are given.

Chapter III discusses air flow through hoods and stresses the importance of the design of the hood face in determining the entry coefficients and thus the flow of air with a given suction.

Chapter IV gives much information on pipe resistance available generally elsewhere but also much assembled from scattered sources. In Chapter V, the procedure to be followed in piping design is demonstrated by a practical example.

The author points out in Chapter VI on dust separators that less significance should be attached to the efficiency of a separator than to the dust content of the cleaned air. He presents, insofar as available, the fundamental principles underlying the design of gravity settling chambers and cyclone separators.

Brief chapters on low-pressure conveyors, on centrifugal fans, and on structural details and system planning follow and the book concludes with chapter X on field measurements and their interpretation. This includes practical suggestions on types of manometers, static and pilot tubes and flow direction finders and their use. The book closes with an apparently adequate index but a table of contents at the front was, strangely, omitted.

All in all the book will serve as a valuable aid to the engineer in laying out the design of an exhaust system or in checking to correct the faults of a system that was built and not designed.—RALPH A. SHERMAN.

Carbon and Alloy Steels *(Gli acciai communi e speciali)*

G. Guzzoni

U. Hoepli, Milan, 1939. 6¾ x 9¾ in., 666 pages. Price 120 L.

The second edition has been entirely rewritten and considerably enlarged, by some 200 pages and 175 figures. The section on alloy constructional steels has been tripled and that on corrosion and heat resistant steels doubled. The selected bibliographies have been brought through 1938. Information from Italian, English, French, German, and American sources, with now and then a bit from Russian or Japanese, is worked into a unified whole.

Some of the features of difference from the 1932 edition are: Inclusion of the solubility of C in ferrite in the Fe-C diagram, discussion of grain size with A.S.T.M. charts, of Mo high speed and Cr-Mn stainless, use of the S curve, emphasis on notches in fatigue, and description of precipitation hardening. Many other modern facts or points of view get brief mention. In general the treatment is well balanced; however the creep data given are useless because they are based on short times and large deformation, accelerated fatigue tests are mentioned as though they were of value, and the discussions of low alloy, high yield strength steels and of controlled atmospheres are so cursory as to suggest that they have not been given due attention in Italy.

The point of view is that of the physical metallurgist, melting and other production factors being only incidentally dealt with. Cast steels are given practically no attention. Those topics that are covered are, on the whole, well handled. Since recent books of similar scope are available in English, the chief value to an English speaking reader lies in the selected bibliographies which list outstanding publications in the world metallurgical literature on the various topics.

The type, paper, micrographs, and the book-making in general, are excellent.—H. W. GILLETT.

Metallurgical Plants. Volume I. Extraction and Production *(Die Hüttenwerksanlagen. Band I. Anlagen zur Gewinnung und Erzeugung der Werkstoffe)*

Hubert Hoff & Heinrich Netz

Julius Springer Verlag, Berlin, 1938. Paper, 8 x 11 in., 468 pages. Price 63 RM.

This book is intended for metallurgical and mechanical engineers and others interested in the design of metallurgical plants. The present volume deals mostly with furnaces and general plant equipment used for the production of raw materials, while the second volume will pertain to equipment for the working and shaping of metals by rolling, forging, extruding and drawing.

Only 12 introductory pages consider the economics of selecting the location of a new plant, transportation means, and structural viewpoints. The book is really a text-book on furnaces, and it may not therefore be surprising that some 70 pages are devoted to furnaces employed in the ceramic, glass, lime, dolomite and cement industries, making it an "almost complete treatise of industrial furnaces." Fuels, combustion problems, furnace construction materials, coking ovens and gas generators are dealt with in 127 pages, and 10 pages are devoted to roasting plants. Furnaces used in the production of iron and steel get 100 pages, while 80 pages are given to non-ferrous metallurgical furnaces. In view of their importance, Cu, Pb, Zn, Al, Sn furnaces are more thoroughly taken up, while furnaces used for the production of Bi, Sb, Ni, Hg, Mg, Ag, Au and Pt are treated more or less sketchily. A 35-page chapter deals with foundry equipment and 15 pages describe cleaning of waste gases. In view of the high price of the book, the inclusion of much data on obsolete equipment for historical reasons, and particularly, the descriptions of furnaces in the non-metallurgical industries represents a burden. A limited number of references are given as foot-notes and a bibliography of about 100 text-books including 3 foreign (American) is appended. The bookmaking is decidedly up to the usual Springer standard, with many space-saving illustrations. It is also up-to-date; latest developments such as electrical blast furnaces, drum furnace for production of pig iron from zinc-bearing pyrite cinders, the Paschke-Peetz process for acid smelting of low-Fe ores and various experimental furnaces for the direct production of steel from ore are discussed.

This volume can be recommended to teachers and embryo metallurgical engineers more than to full-fledged plant designers, although the last may in certain cases find it helpful.—ERICH FETZ.

Electrochemistry of Molten Salts

(Elektrochemie geschmolzener Salze)

Paul Drossbach

Verlag Julius Springer, Berlin, 1938. Paper, 6½ x 9½ in., 143 pages. 12 RM.

The author, a professor in the Technische Hochschule, Berlin, states in the preface that this is not intended as a text book nor as a discussion of technical processes, but instead to present the scientific foundation for the electrolysis of fused salts. Consequently 100 pages are devoted to theory, with more than half of them a mathematical discussion of thermodynamics and their application to the matters in hand, and the balance on electromotive forces, conductivity and density of fused salts, Faraday's law, energy consumption, methods of measurement of polarization voltage, and apparatus for electrolysis of fused salts.

The final 44 pages are devoted to a discussion of laboratory investigations on the fundamentals underlying the production of Li, Na, K, Rb, Cs, Be, Mg, Ca, Ba, Sr, Al, rare earth metals, Cu, Ag, Fe, W, Zn, Cd, Sn, Pb and Bi. No attention is paid to commercial production of any of these metals, nor to the patent literature which bulks so large in many German monographs. The author closes with a plea for scientific study of fused salts in general, without particular reference to whether the metal studied can be economically produced from the fused salt or whether the particular salt studied is the one that would be used from economic considerations. "Primitive methods" of trial and error should, he argues, be replaced by a scientific examination of every variable. The book is devoted to the attempt to clarify these variables and to develop fundamental principles.—H. W. GILLETT.

Crucible Steel To Make Ledloy

The Crucible Steel Co. of America has received license to manufacture "Ledloy" under Inland patents. Ledloy is the new lead-bearing steel developed and introduced by the Inland company last year. A small amount of lead is added to the steel, so uniformly dispersed that it has no effect upon any physical properties, except to increase machinability. It is claimed that machining speeds in production runs of hot rolled and cold finished bars can be increased 30 to 100 per cent beyond the practical limits of ordinary steel, and tool life is extended 200 per cent or more.

The licensees to April 1 for making "Ledloy" include the following companies:

Bethlehem Steel Co.
Carnegie-Illinois Steel Corp.
Crucible Steel Co. of America
Guest, Keen & Nettlefolds, Ltd. (British)
Joslyn Mfg. & Supply Co.
Keystone Steel & Wire Co.
Northwestern Steel & Wire Co.
Pittsburgh Steel Co.
Youngstown Sheet & Tube Co.

Major Bull's Library at Battelle

The reference library at Battelle Memorial Institute has just been enlarged by 600 valuable bound volumes as the result of a gift from the family of the late Major Robert A. Bull.

Major Bull was a recognized technical leader in the foundry industry, twice president of the American Foundrymen's Association, and member of many other technical societies. During the years of his service to the steel castings industry, he gathered an extensive private technical library. It is this collection that has been entrusted to Battelle in order that it may remain in active use.

The Battelle library now comprises over 7,500 volumes pertaining to metallurgy, ceramics, chemistry, fuels, and related subjects. The Bull Collection, which is exceptionally complete in the American and English foundry field, greatly adds to its usefulness for metallurgical research.

● Clarence E. Sims, metallurgical supervisor, Battelle Memorial Institute, Columbus, Ohio, is visiting in England for the purpose of studying developments in the iron and steel industry.

Studies Planned by the Ferrous Metals Committee

Metal cutting and welding with city-gas-oxygen torches; recent advances in the use of prepared gaseous atmosphere furnaces; and new heat-treating processes which have been developed in the past year were the three subjects singled out for study and analysis during 1939 by the Ferrous Metals Committee, Industrial Gas Section of the American Gas Association, at a recent New York meeting. The new Chairman of this group, acting in behalf of improved applications of gas to the iron and steel industry's heating jobs, is Clayton S. Cronkright, Public Service Electric & Gas Company, of New Jersey.

Paramount in the committee's mind this year will be the economic considerations involved in the use of city gas in the three fields noted. Actual cost studies of numerous applications will be made. Several and frequent interim bulletins will be issued to disseminate useful data to the trade.

News from A. G. A. headquarters indicates that the most likely "first" in the committee's series of bulletins will concern cutting and welding with gas—not a new use for city gas, but one in which interest has revived noticeably of late, and one which has never been fully capitalized upon by the metal industry. New standards of economy are being established in the use of city-gas-oxygen torches, particularly for scarfing, scaling and deseaming. One of the largest steel companies has recently found that one cubic foot of natural gas can do the job of one cubic foot of much more expensive acetylene, and with only 5 per cent more oxygen. Other steel industry leaders are getting similar results in manufactured as well as natural gas territories.

Studies of prepared gaseous atmosphere units will cover all types of equipment for generating (from city gas) both protective atmospheres and process atmospheres. Apparatus by the American Gas Furnace Co., C. M. Kemp Mfg. Co., Surface Combustion Corp., Mahr Mfg. Co., General Electric Co., Westinghouse E. & M. Co., Sentry Co., Lithium Corp. of America; Electric Furnace Co., and J. P. Devine Mfg. Co., will be considered both functionally and economically.

New heat-treating processes to be reported upon include: Air furnace heating, cyaniding in gas atmospheres, and high speed steel units, such as the new Charmo, represented as record-setters in preventing decarburization.

Udylite Corp. Acquires Bright Nickel Corp.

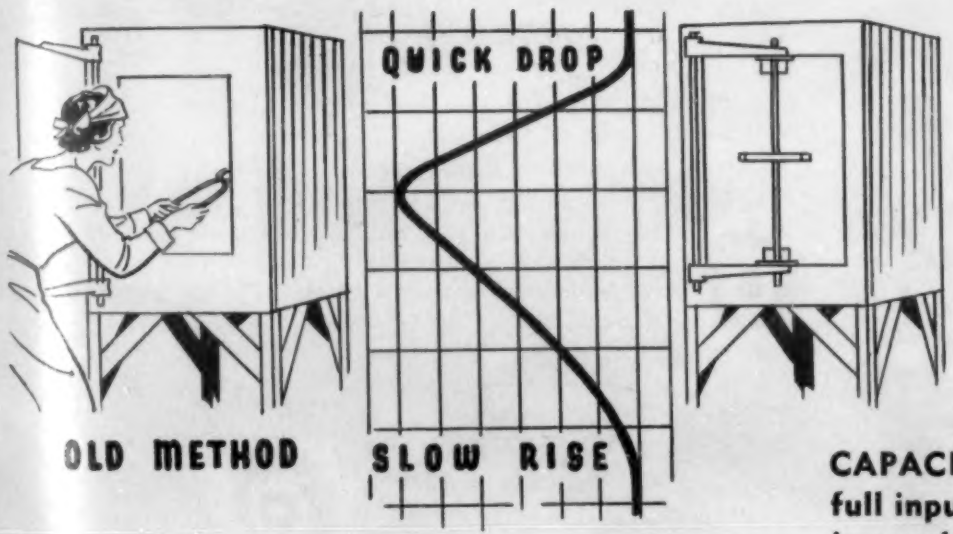
All the capital stock of the Bright Nickel Corp., Detroit, owners of the basic Schlotter patents covering bright nickel plating process, has been acquired by the newly-formed Udylite Corp. Preceding the acquisition of the capital stock of the Bright Nickel Corp., the Udylite Co. formed a new organization to be known as The Udylite Corp. which has taken over all of the business and assets of the Udylite company. This company is widely known as one of the leading plating and polishing supply and equipment houses in the country.

The advantage of the bright nickel process results from materials coming from the tanks bright and shining, thereby eliminating buffing, with a consequent saving in time, labor and money. The Bright Nickel Corp. will be operated as a wholly owned subsidiary of The Udylite Corp.

The personnel and policies of The Udylite Corp. will remain the same as those of The Udylite Co., which it supersedes and the same management will continue. Officers of the new corporation are as follows: Charles Awkermann, chairman of the board; L. K. Lindahl, president; C. H. Reeme, vice president; and Horace Maynard, secretary.

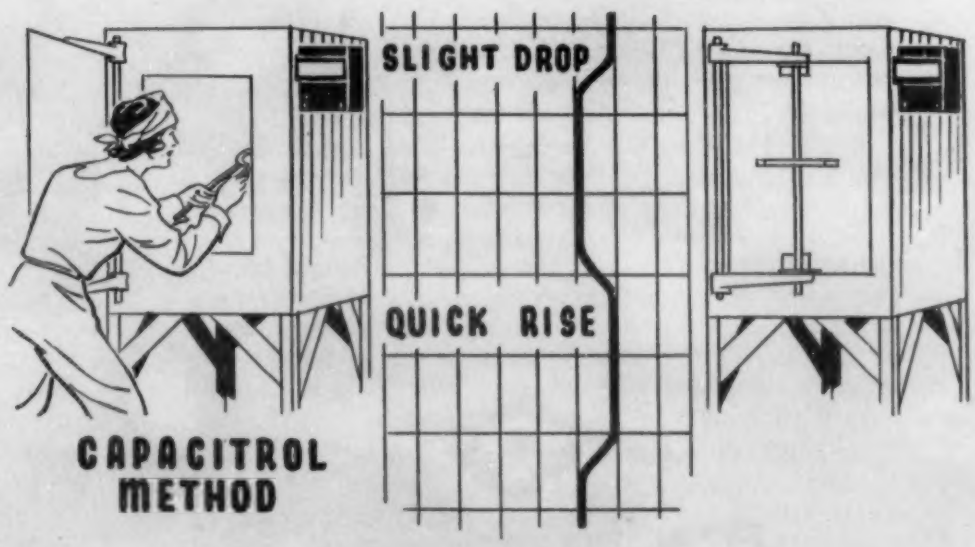
The new corporation, through the acquisition of the Bright Nickel Corp., can now offer the metal finishing industries a more complete range of products and processes, increased technical facilities as well as an organization equipped to handle a more rounded-out variety of metal finishing problems.

(Continued on page MA 246)



INCREASE OF 6 PRODUCTION HOURS PER DAY WITH CAPACITROL

Production equivalent to two additional working hours are gained each eight-hour shift, per furnace (a total of six hours in three shifts) in the production of tubes by one of the largest electrical manufacturers in the country, since CAPACITROL "No-Contact" temperature controllers were installed. With the old control system, each opening of furnace door for servicing production dropped temperature 150°.



"No-Contact"
Temperature Control

CAPACITROL controller permits increase of heat to full input, resulting in slight drop of temperature during each door opening and the time required to bring temperature back to operating level (400° F.) is considerably shortened, thereby advancing production 25%. Engineer states CAPACITROL will pay for itself in several months. No known method of temperature control can equal CAPACITROL "Hair-Line" control.

REPORT 1345 is the basis of these facts.

CAPACITROL literature on request.

WHEELCO INSTRUMENTS CO.

1929 SOUTH HALSTED STREET · CHICAGO

New Curricula at Brooklyn Polytechnic

New curricula leading to the degree of bachelor of metallurgical engineering and bachelor of aeronautical engineering, respectively, have been added to the program of the Polytechnic Institute of Brooklyn according to an announcement by President Harry S. Rogers.

Although many of the subjects embraced in the new curricula have been offered for years, either as required or elective prerequisites to the mechanical engineering degree, the growing demand for students specially trained in both metallurgy and aeronautics has been responsible for the inauguration of the new degree curricula. Although the matter has been under consideration for some time, the decision to offer the courses was not made until careful analyses had indicated that definite opportunities for students existed in both fields. Pres. Rogers said:

> We have a dual responsibility, both to industry and to our students, and I know of no technical school in the country where this responsibility is so definitely assumed as at the Polytechnic. The faculty members directing these new courses have been studying the practices and the scientific developments taking place in industry. A surprising number of new developments in industry are actually born right here in our laboratories and our students frequently become familiar with what later becomes accepted commercial practice while they are still undergraduates. It is with this sense of responsibility and thorough preparation of facilities that we now offer the new curricula.

The phenomenal growth of the metal industries has opened one of the most promising fields for metallurgical research in recent years. New alloys, new treating methods and new metal fabricating practices have developed a need for new workers, capably trained in physical metallurgical lines.

By virtue of its metropolitan location, and ease of access, the Polytechnic is in the center of an important metallurgic field. Twenty per cent of all the copper refining in the country is actually done in Brooklyn; 50 per cent within a 40-mile radius. All the large fabricators of copper and copper alloys, Westinghouse, General Electric and Western Electric, besides hundreds of smaller manufacturers of raw and finished metal products have plants within the Greater New York area.

The aeronautical engineering curriculum is one for which numerous requests have been made by students, engineers and manufacturers associated with the aircraft industry, according to Dr. Rogers.

Bessemer Gold Medal to James Henderson

The Council of the Iron and Steel Institute, London, England, has decided to award the Bessemer Gold Medal to James Henderson. The Bessemer Medal was founded by Sir Henry Bessemer and is awarded annually for distinguished merit in promoting the technical and metallurgical development of the iron and steel industry; it is the highest honor which the Institute can give.

James Henderson has had a remarkable career. For 45 yrs. he was associated with the technical development of the Frodingham Iron and Steel Co., Ltd., in North Lincolnshire and held all positions from chief metallurgist to managing director. During that period the Works became one of the most important in the country and were associated with such important developments as the introduction of the Talbot direct metal process, the use of blast-furnace gas in blowing and power engines, and the installation of modern plate mills.

Mr. Henderson is now deputy chairman of the renamed Appleby-Frodingham Steel Co., Ltd., and a director of the United Steel Companies, Ltd.; he is past-president of the British Iron and Steel Federation and of the Lincolnshire Iron and Steel Institute; a former chairman of the Lincolnshire Ironmasters' Association and of the Iron and Steel Industrial Research Council; a member of Council and honorary treasurer of the Iron and Steel Institute. He is one of the only two Englishmen whose services to the industry have been recognized by nomination to honorary membership of the Verein deutscher Eisenhüttenleute.

Army Establishes a Gage Laboratory

The Ordnance Department of the United States Army will establish a gage laboratory at the Carnegie Institute of Technology this spring, thus considerably increasing facilities for research and industry in the Pittsburgh district. The primary purpose of the laboratory is to make available standard measurements of the greatest accuracy for the machines which produce Army equipment. More than $20,000 worth of delicate precision instruments, accurate to the hundred-thousandth and millionth of an inch, will be installed in a laboratory in Industries Hall at Carnegie Tech.

The laboratory will be operated under the general supervision of Dr. Webster N. Jones, director of the College of Engineering at Tech, and Major C. H. Morgan, executive officer of the Pittsburgh Ordinance District. Professor C. C. Leeds of Carnegie will be in charge of the laboratory.

The equipment makes possible measurements within two-millionths of an inch by means of the Van Keuren light wave equipment used to determine the wear on Johanssen precision measuring blocks or diameters of ball bearings and similar measurements where great precision is essential. Another piece of equipment measures length to the hundred-thousandth of an inch. Other apparatus includes a screw thread testing machine, comparators, microscopes, micrometers, surface plates, straight edges, levels, parallels, and squares. All precision equipment has been calibrated at the U. S. Bureau of Standards, and the tabulated calibrations are part of the laboratory records.

This laboratory is a valuable asset to Carnegie Tech, making available a place where instruments may be calibrated prior to research investigations. Industries in the district will also use the equipment.

The Ordnance Department will use the laboratory to train ordnance reserve officers as Army inspectors of ordnance, and employ its facilities to calibrate and inspect gages on current manufacturing orders. The laboratory will be of tremendous value for national defense in the event of emergency by facilitating check of inspection gages and accelerating of inspection work. The laboratory will be formally dedicated the latter part of April.

J. J. Crowe Honored

John J. Crowe, research engineer for Air Reduction Sales Co., New York, has been awarded the 1937 James Turner Morehead Medal, sponsored by the International Acetylene Association. The medal, which is awarded annually for outstanding work in the production or utilization of calcium carbide and acetylene, was presented to Mr. Crowe during the opening session of the 39th convention of the International Acetylene Association in Houston, Texas, early in March. The inscription on this year's Morehead medal, "For his unceasing and successful technical activities", is indeed a fitting tribute to the recipient.

Zinc Institute's Annual Meeting

The 21st annual meeting of the American Zinc Institute will be held at the Hotel Statler, St. Louis, Mo., on Monday and Tuesday, April 17 and 18. On Monday the Institute will report on its activities during the past year. The Institute's promotion work will be specially featured. On Tuesday several speakers will be heard on the subject of the market for zinc coated products. The program will also include a number of technical topics of vital interest. The Steel Corporation's technicolor movie "Men Make Steel" will close the afternoon session. Entertainment features will include the annual dinner which will be held on Monday evening.

● R. S. Van Note, since 1929 New England representative, has been appointed assistant manager of sales by the C. M. Kemp Mfg. Co., Baltimore, Md.

(Continued on page MA 249)

Steel Purchasers Beware!

According to a recent warning issued by the Purchasing Agents Association of New York to its membership, steel buyers should be extremely cautious in dealing with strange steel salesmen representing foreign concerns. Within one week 4 association members reported that officials of their companies had been approached by a man purporting to represent a certain European steel maker (the association has the name) and in 2 instances an order was given for "samples" of tool steel. Inasmuch as the swindler in question may approach some of our readers not members of the Association, we are glad to publish part of the warning, with the permission of the association:

The technique is the same as has been employed periodically during the past 10 yrs: A suave salesman with the best of Continental manners, through certain credentials and impressive letters of introduction, gets an interview with the president, or some other executive of the company; but never with the purchasing agent.

His sales talk is somewhat technical and not too definite as to details. He states prices in francs, which the buyer might assume to be French francs but is later invoiced in Swiss francs. He creates the impression that dimensions are in feet, when in fact, meters are specified.

Here's the crux of the swindle: The order usually is incorporated in a letter rather than a purchase order and always ambiguous in terms—the terms being suggested by the salesman. The purchaser believes he is ordering a "sample", but when the shipment arrives, his "sample" consists of several hundred pounds of bars of various lengths and sizes and billed at from $750 to $1200. In an earlier epidemic of this swindle, one large company was billed for $4,000 for the stuff. The price quoted is about 95c a lb. and the steel is found to be the equal or inferior to our domestic product.

We suggest the following precautions for protection against this fraud:

Use only your own order blanks; prepare your own wording.
Be sure the maximum quantity is clearly stated in the order in dimensions you understand.
Be sure you specify in your order the maximum amount of the order *in dollars*.
Advise all officers, superintendents and foremen to be on their guard.

This advice may appear elementary—but some of the large concerns of the country have been misled because elementary precaution was not taken.

American Council of Commercial Laboratories

Leading research and testing laboratories of the country have mutually bound themselves together in the American Council of Commercial Laboratories to maintain testing, research, inspection and the laboratory art as a whole upon a high plane and to conduct their operations in such a manner as to insure competency and reliability in whatever they may undertake. Member laboratories are located from coast to coast with branch laboratories and inspection stations in every important city and industrial center in the country. Membership in the Council is open to commercial laboratories which qualify to the strict requirements and pledge to abide by the high code of ethics set up in the Council By-Laws.

Formation of the Council has taken on important aspects in recent months not only in the line of research, testing and inspection of new product developments but with the scientific equipment and trained personnel of experts of the combined laboratory group the commercial testing laboratories have set up through the Council a means of assisting in the mobilization of industry in time of emergency.

The Council has prepared a brochure listing its aims and showing the scope of the work and equipment of member laboratories. Copies of the brochure may be obtained by writing D. E. Douty, secretary, 1415 Park Ave., Hoboken, N. J.

● The ninth semi-annual Eastern Photoelasticity Conference will be held at Cornell University, Ithaca, N. Y., on Saturday, May 13. The Committee on local arrangements, of which Prof. F. G. Switzer of the College of Engineering at Cornell is chairman, expects an attendance of approximately 100 scientific workers in this field, both from college faculties and from the research staffs of various industries. The program of technical papers will be supplemented by an exhibit of the latest equipment for photoelastic research, and demonstrations in the Cornell laboratories.

Free Service Department

Replies to box numbers should be addressed care of METALS AND ALLOYS, *330 W. 42nd St., New York.*

POSITION WANTED: Professor of Metallurgy desires position for three months starting June first. The possibility of developing into permanent position of added interest. Ph. D. in physical chemistry and physical metallurgy. Four years of industrial experience and eight years of teaching experience in engineering schools. Will consider either teaching or industrial position. Box MA-127.

HELP WANTED: Representative with ability to sell bronze and brass ingots in Northern New York State and Pennsylvania, knowledge of foundry practice desirable. Box MA-131.

HELP WANTED: Young metallurgical or foundry engineer, with some practical molding experience, for sales of alloys and development of markets for alloy iron and steel castings in central western territory. Box MA-132.

POSITION WANTED: Metallurgist desires technical sales position. Employed, and for the past eight years, by nationally prominent manufacturer. Experienced in all phases of heat treating, physical testing, processing, fabrication, application and production of plain carbon, alloy and tool steels. Box MA-133.

HELP WANTED: Man for sales or outside service work on pyrometers; experience not necessary if capable of learning, and willing to start at moderate salary. Box MA-134.

HELP WANTED: Experienced pyrometer men for New York and Philadelphia, capable of producing and supervising district sales and services. Unlimited opportunity with growing organization. Proper remuneration. Box MA-135.

POSITION WANTED: X-Ray operator thoroughly experienced desires suitable connection. Box MA-136.

● Dr. John F. Thompson, chairman of the Whitehead Metal Products Co., Inc., has announced that Thomas M. Bohen, vice-president of the company, had been elected president to succeed the late J. J. Whitehead. At the same time Herbert G. Fales, a vice-president of The International Nickel Co., Inc., was elected vice-president and Clayton D. Grover was made assistant to the president. The Whitehead company is a wholly owned subsidiary of International Nickel.

● H. P. Dolisie, of Montreal, Canada, and Henry Booth, of New York, have been elected president and vice-president respectively of International Acetylene Association for 1939. H. F. Reinhard, also of New York, was re-elected secretary. The election was held during the Association's 39th convention held early in March at Houston, Texas.

● In order to expand their services to industry so as to include not only metal cleaning but also certain production phases of finishing, the Detroit Rex Products Co., 13005 Hillview Ave., Detroit, Mich., has expanded its sheet metal manufacturing division. I. J. Belanger, formerly of the Belanger Fan & Oven Co., Detroit, has been appointed manager of this division.

trends

BY EDWIN F. CONE, EDITOR

Carbon Linings for Blast Furnaces

Our first article in this issue deals with a subject of prime interest to operators of American blast furnaces—carbon linings for certain portions of pig iron furnaces. The trend in Germany, according to an American engineer who recently visited that country, is decidedly in this direction. He reports some striking applications of carbon block linings with highly satisfactory results. This article, written by an authority on refractories and ceramics who has spent much time in Germany, England and the United States, discusses some of the results of such linings in Germany, Russia and Sweden. None are yet used in the United States.

Spectrographic Control

The installation late last year of a complete spectrographic laboratory by the Ford Motor Co., at its Dearborn plant is a significant development in a comparatively new field—control of the composition of heats of alloy iron. It is being used to largely displace the use of chemical analysis. It is stated that it requires only 8 min. to analyze with the new equipment 6 different samples for 6 elements—a total of 36 determinations made in a fraction of the time needed for chemical analysis. The advantage, both as to time and to accuracy, is obvious in a foundry where several hundred tons of metal is poured a day.

Vacuum Melting

Every now and then we hear something about vacuum melting. Outside of Rohn's plant in Germany, vacuum melting is still in the research laboratory stage, so far as we can learn. Ordinarily instead of using a vacuum, one will use a neutral or a helpful atmosphere, for it is generally the atmosphere rather than the pressure that counts. There is evidence to the effect that the atmosphere is being considered as a possible factor in all melting operations.

Insulating Firebrick

According to an authority the use of insulating firebrick is on the increase. Economies have been achieved by several steel companies by using this type of brick in covers for soaking pits—a lighter cover, requiring less power and lighter motors, as well as longer service life. Fuel savings are also cited.

Light Metals Replacing Steel in Germany

According to a news item from London, published in *The Iron Age,* Gen. Von Hanneken of Germany is quoted as saying that wherever possible, non-ferrous metals, especially magnesium and its alloys, are being substituted for steel and iron. Industries have been ordered to supersede iron with light metals and as a result the automobile trade is using magnesium alloys to an increasing extent. Armament plants have first call on iron and steel supplies. It is stated that Germany has unlimited supplies of magnesium. This trend will bear watching since German metallurgists have always been skilled in such developments.

Low-Alloy Steel Castings

Analogous to the development of the low-alloy, high strength steels for structural purposes is the production of low alloy steel castings for side frames, bolsters and so on for freight and passenger cars. This is in line with the trend to lighten the weight so as to increase the pay load. Conspicuous among such steels are the nickel-manganese and the manganese-vanadium cast steels as well as the later development of a titanium-manganese alloy steel. Research work in this field is progressing rapidly.

Pearlitic Malleable Iron

The development and exploitation of pearlitic malleable irons is pointed to as one of the greatest single contributions of the malleable iron industry this past year. New uses for this material are being sought and predicted. The versatility of pearlitic malleable as a material, as pointed out by H. A. Schwartz in *Steel,* is demonstrated by the rather wide variety of properties desired for various purposes and the correspondingly wide range in service conditions to which this material, produced by different vendors, is suited. As the years go by, he says, there will perhaps be "some possibility of the standardization of properties desired and methods of manufacture leading to a reduction in the number of such materials on the market." This situation may be clarified by new specifications by the A.S.T.M.

Better Steel Castings

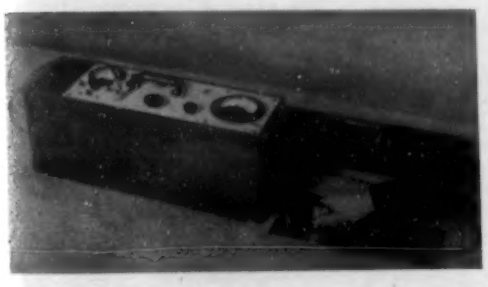
A tendency in the right direction is the meeting each month of operating executives of the American steel casting industry who exchange technical information "with the dual purpose of improving the quality of production and increasing production efficiency." This has been developed by the Steel Founders' Society of America.

Inspecting with the Spectrograph

We understand that the spectrograph is being used by a large department of the U. S. Government in a rather unusual manner—inspection of material on a large scale. Among some of the advantages claimed are a larger saving in time and pronounced accuracy.

More Uses for Steel Castings

New applications for steel castings are reported on the increase. Engineers of the Ford Motor Co. have announced that the utilization of steel castings has been extended in that organization so that now 149 lbs. of such castings are used in every car.



New Equipment and Materials

Manufacturers are invited to send to the Editor items which are suitable for this Department. Illustrations are acceptable, preferably in the form of cuts no more than 2 in. wide.

The Profilometer Measures Surface Roughness

The roughness of a surface consists of the finely-spaced irregularities which usually determine the "finish" of the piece. These irregularities are seldom more than a few thousandths of an inch wide, and much less in depth. Several hundred such wiggles are covered in traversing an inch of the surface. Roughness measurement consists of determining the magnitude of these irregularities.

The "Type P Profilometer" developed by the

Physicists Research Co., Ann Arbor, Mich., measures a running average of the height of the irregularities which constitute the roughness of the specimen. The tracer shown in the illustration carries a small diamond point which is held against the surface by light spring tension. It is sharp enough to bottom the irregularities, but does not scratch or otherwise damage specimens of ordinary hardness, such as steel, cast iron, glass, bronze, etc.

The motions of the tracer point are transformed to electrical voltages in the tracer, and amplified and measured by the instrument. The automatic averaging feature is provided by the electrical meter, which is calibrated directly in inches. The meter takes an rms (root mean square) average, which is the average commonly used for oscillating quantities. For a simple curve, the rms value is 35% of the peak to valley height.

The Type P Profilometer is designed for shop use. It requires no external connections, and can be carried to any job and measurements made in place. The tracer is about the size of a pack of cigarettes, and measurements can be taken on almost any surface on which this tracer can be placed. In many cases, readings have been made with the part still on the producing machine, and frequently with the machine in operation.

Mechanically, the measurement requires no more skill than using a micrometer. The tracer is moved across the surface whose roughness is to be determined, and the meter reads a continuous running average of the height of the surface irregularities. For convenience, the scale is calibrated in microinches. One microinch is .000001 in. The tracer can be moved manually or mechanically as desired. For very smooth surfaces (less than 3 micro-inches), mechanical trace is recommended. It is not necessary to press the tracer hard against the surface, as its own weight is sufficient. The reading obtained is independent of the pressure between the tracer and the specimen. The readings obtained are independent of the speed of trace over wide limits. A speed of trace of about 1 in. per second is suitable.

The reading of the instrument is determined by the roughness, and is not affected by the curvature of the piece. It can be used on flat, cylindrical, or curved surfaces of wide variety and shape. Adjustment for surfaces of different curvature is made by means of the small knob on the top of the tracer. This knob simply raises or lowers the tracer point to insure proper contact with the surface, and does not affect the reading.

A Redesigned Magnetic Separator

The Stearns Magnetic Mfg. Co., Milwaukee, Wis., which produces an extensive line of magnetic separators and magnetic friction devices, has completely redesigned its "Type DH" drum type magnetic separator. Separators of this type can now be applied to both wet and dry operations. The vibrating feeder now provided for dry operation affords a uniform flow of material and accurate control of the material to conform to the type of separation desired.

The Type DH is designed particularly for the purpose of removing impurities from finely ground materials. The vibrating feeder delivers free-flowing material in a uniform layer into the magnetic field where the impurities are eliminated. The even distribution of the material allows close and intensive contact with every particle as it passes through the magnetic field.

In the wet operation arrangements are made for an under feed of the slurry, contact of the flowing material being made in a dense, highly concentrated magnetic field. Impurities thus extracted are disposed of as the cylinder rotates, conveying them out of and beyond the flow where they are immediately discharged.

The Type DH magnetic separator is so designed that it can be built with a multiple drum arrangement, thus providing for the extraction of the most feebly magnetic particles by subsequent passing through various magnetic zones. The drums are built in various sizes, depending on the capacity desired.

Machine for Sheet Metal Fabricators

The new "Quickwork Combination Throatless Shear and Flanger" is a compact, versatile, low cost unit that will handle a wide range of sheet metal fabrication. It is of simplified unit type design for greatest utility—as a shear, as a flanger, or as both—as bench type or pedestal mounted machine—for production shop work or as portable equipment out on the job.

As a shear, it handles all straight and irregular cutting, including full circles and curves, both concave and convex. Material of any width or length can be cut. The smooth, even action of the self-feeding rotary cutters makes it easy to follow the most intricate layouts.

A simple, quick change of heads converts the

machine into a flanger which is equally simple and easy to operate. The shoulders of the flanging rolls act as a guide for the depth of flange. Attachments and rolls can also be furnished for U-ing, wiring, special flanging and forming.

This new machine is furnished arranged for two cutting and flanging speeds. It is ball bearing equipped throughout. Cutter and roll shafts have lifetime ball bearings and all drive mechanism runs in a bath of oil; thus reducing the lubrication job to a minimum. Complete information on this machine can be secured by writing the Quickwork Co., 400 W. Madison St., Chicago.

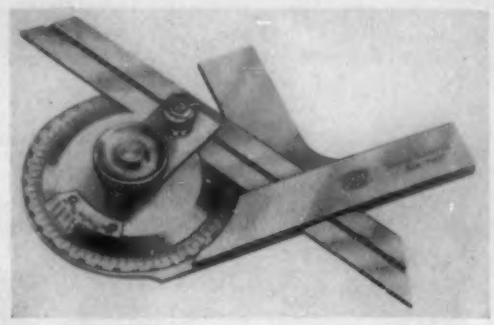
Bulk Fused Silica for Molding Sand Mixtures

Interesting possibilities in the way of improved molding sand mixtures are claimed through the use of fused (vitreous) silica as a new form of silica now available in bulk on a tonnage basis. The outstanding characteristic claimed for this form of silica is its extremely low expansion, producing mixtures of greatly increased resistance to thermal shock.

Combined with gelatinous silica as a binder having practically the same low expansion, molds of maximum indifference to thermal shock can be produced.

Samples of Vitreosil (vitreous silica) for this purpose, and any possible technical assistance will be gladly supplied by the manufacturers, The Thermal Syndicate, Ltd., 12 East 46th St., New York.

Solvent for "Piston Varnish"



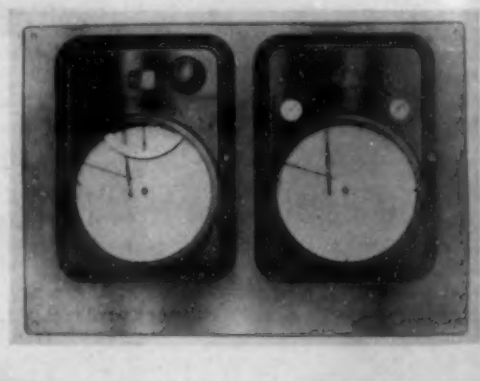
The chemical department of The Curran Corporation, Malden, Mass., announces the discovery of a novel aromatic solvent compound which is said to quickly dissolve "piston varnish". The new solvents are vaporizable at combustion chamber temperatures and the saturated vapors, upon cooling and reaching their dew point, precipitate copious quantities of the hot tar solvent. The dissolved piston varnish and/or carbonaceous tars may be conveniently removed from the engine by draining the old motor oil. The normal dose of 32 oz. should be administered just before oil change time, then any residual film or deposits will be completely removed from the engine with the draining of the motor oil.

For the time being this new solvent will be sold as "Gunk Piston Varnish Solvent."

Mauser Universal Bevel Protractor

The George Scherr Co. announces a "New Universal Bevel Protractor" of Mauser manufacture, producers of the well-known Mauser vernier calipers and height gages. This precision tool has been designed to meet the requirements of toolmakers, engineers, layout men and mechanics. It may be used for all types of work where angles must be laid out or measured. The dial is graduated in degrees for the full circle in 4 x 90 = 360 deg. A vernier is provided which gives readings within 5 min. of the arc (1/12th of a degree).

The graduations on both the main dial and



on the vernier are very finely etched with jet black markings, making readings quick and simple. The tool may be obtained with either 6, 8 or 12 in. blades, which are bevelled at each end to 45 and 60 deg., respectively. The back of the tool is finished flat so that it may be flush when laid on work or paper. The dial may be clamped rigidly by a thumb nut, while the blade may be clamped independently of the dial.

Layout men find the Bevel Protractor essential in laying out angles while toolmakers use it constantly to check their work. The new Mauser Universal Bevel Protractor has been placed on the market as an item for the individual mechanics' tool kit. The George Scherr Co., 128 Lafayette St., New York, N. Y., is the exclusive agent for the United States for Mauser precision tools.

Flow Ratio Control

The rate of flow of one fluid in definite ratio to the flow of a second fluid—automatically controlled—is accomplished by means of a new "Flow Ratio Controller", recently developed by The Bristol Co., Waterbury, Conn. One of the features of these controllers is an arrangement which permits changing the ratio at any time by simply turning a knob on the outside of the case.

Thus, a 5:1 ratio between the flow of air and fuel gas, a 4:1 ratio between the flow of natural gas and artificial gas, a definite ratio between two different kinds of gases in a furnace, or a definite ratio between the

lean oil and wet gas entering an absorber—these are some of the useful applications for these new instruments.

Bristol's Flow Ratio Controller consists of two instruments—one a standard flow recorder and the other a standard flow recorder controller. The rate of flow is measured and recorded by one instrument, which also sets the control point on the second. The latter then records and controls the flow proportionately to the first, depending upon the ratio selected. Bristol's revised Catalog No. 1051 describes these new instruments.

Hoist Plugs Into Lamp Socket

Combining the dependability of big scale hoisting equipment with compact, light-weight convenience—this is what CM engineering has achieved in the new "Comet Hoist." Easily carried and installed by one man, the Comet is powered by a specially built heavy duty, high torque motor that runs on an ordinary light circuit or 3-phase power line. Just plug in, and the hoist is ready to go. No special installation or accessories needed. Use it anywhere. The compact design and ease of operation make the Comet especially valuable for service on production lines in large plants.

Yet, the price is low enough to make it ideal equipment for the smallest shop.

The construction of the Comet is compact and rugged, yet exceptionally light in weight. Precision ball bearings are provided at each rotating point. Gears are precision machined of heat-treated alloy steel. Controller, with patented "delayed reversing" feature, operates easily with one hand and affords an extremely sensitive control for lifting the load distances of a fraction of an inch. The brake is pointed to as smooth, quick acting, positive—prevents drifting of load—is easily adjusted. Upper and lower safety stops automatically limit travel of load hook.

The Comet is offered in four capacities 250, 500, 750 and 1000 lbs., and several speeds. The 500-lb. size weighs only 85 lbs. Construction and operating details are fully illustrated in literature available by writing the Chisholm-Moore Hoist Corp., 346 Fremont Ave., Tonawanda, N. Y.

New Paving and Slag Breaker

A new "Cushioned-Air" paving breaker, known as the "CC-80," has been announced by Ingersoll-Rand. It is an 80-lb. machine, and incorporates the most recent developments of the I-R line of paving breakers, pile drivers, slag remover, etc.

The air-cushioned piston on this breaker results in an easier holding hammer, especially at higher air pressures. Because there is less shock on the wearing parts and because the piston cannot strike the front-head, there is claimed less breakage and less upkeep. Other design features include a larger anvil-block bearing which insures correct alignment; an extra large built-in lubricator; reverse buttress self-locking threads on the fronthead bolts and the latch bolt of the steel retainer; and numerous additional refinements. Complete information is contained in form 2530, copies of which are available from the Ingersoll-Rand Co., 11 Broadway, New York City.

Bronze Welding Rods

Compressed Industrial Gases, Inc., Chicago, has announced two new bronze welding rods. These rods are known as "CIG No. 400 Ready-Fluxed Bronze Rods" and "CIG No. 401 Ready-Fluxed Manganese Bronze Rods." As their name implies, they are completely flux-coated throughout their entire length all ready for the oxy-acetylene welder to apply in his welding jobs.

This improvement in bronze welding rods is claimed more than simply an innovation. It is the most important step that has been made in bronze welding rod manufacture because it controls the even introduction of the chemically correct flux throughout the entire brazing operation. It prevents the weld from getting too much or too little bronze and completely shields the molten metal from the time the weld area is first tinned until the job is completed.

The CIG Ready-Fluxed Bronze Rods are designed for application in any type of bronze welding of all metals on which bronze is normally used without the use of additional flux. The CIG No. 401 Ready-Fluxed Manganese Bronze Rods are particularly desirable for bronze welding of cast iron. In bronze welding applications where powdered flux is used, it requires approximately 1 lb. of flux for each 25 lbs. of bronze deposited, or about 4 lbs. of flux to each 100 lbs. of bronze. Since this amount of flux costs the user approximately $5 it can readily be seen that considerable savings will be attained in the actual cost of the product itself. In addition, there are substantial savings to be effected in time and labor and oxygen and acetylene gases.

CIG "Ready-Fluxed" Bronze Rods are made in the Chicago plant of the Hollup Corp., a subsidiary of Compressed Industrial Gases, Inc. Conveniently located stocks are maintained at the District Offices of the companies in principal cities in the United States.

5 GOOD REASONS why DU PONT SALTS are preferred for LIQUID BATHS

WIDE OPERATING RANGE: Consistently good results can be obtained within wide variations of temperature and operating conditions.

ECONOMY: A result of unusual stability and efficiency in operation; low rate of replenishment and small dragout losses.

UNIFORMITY: All du Pont salts are uniform mixtures with a guaranteed cyanide content.

SERVICE: Our trained metallurgists are at your call to cooperate with you in the solution of any liquid bath problems. Just call or write our nearest office.

STABILITY: Du Pont salt baths have a low rate of decomposition. Bath activity is easily maintained with moderate replenishment.

Plan to visit the du Pont exhibits at the *Golden Gate International Exposition* in San Francisco and at the *New York World's Fair.*

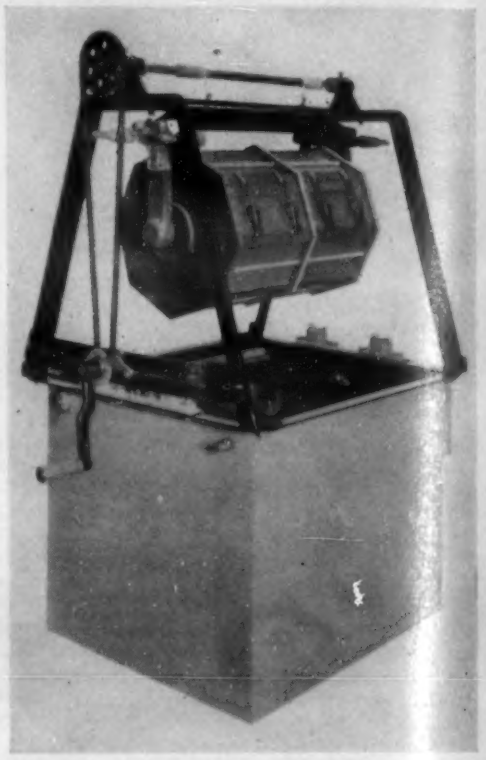
"Automatic Emulsifying" Safety Grease Solvent

The research laboratory of The Curran Chemical Corp., of Malden, Mass., has developed a new hydro-degreasing safety solvent to be used for degreasing and deoiling metal airplane fuselage and engine nacelles of aluminum skin construction. In addition to possessing excellent wetting out and solvent action upon heavy grease and carbon exhaust smut, this new solvent is said to have "automatic emulsifying" properties when it is associated with a substantial amount of water.

Practical tests made in the field show that large military or transport planes may be deoiled and degreased by simply spraying the under fuselage and the engine nacelles with the solvent composition at apparently a very low cost. Then the solvent is sluiced and washed away with a water hose which automatically emulsifies the grease and oil. The oils and dirt are removed in a milky "oil-in-water" type of emulsion which entirely eliminates fire hazards and clogging of the sewer drains. It is stated that the solvent is safe for use on aluminum or magnesium alloys under all possible conditions and concentrations. This new solvent will be sold as "Gunk Concentrate P-92—Aviation Grade."

Durable Transparent Metal Coating

A new transparent protective metal coating which is said to withstand the action of sunlight, moisture and climatic changes is announced by The Fales Chemical Co., 545 Fifth Ave., New York City. It is claimed that this coating—"Seal-Cote"—has been used successfully with copper, brass, bronze, steel and other metals and has preserved their original finish even when exposed to the weather for at least six months.

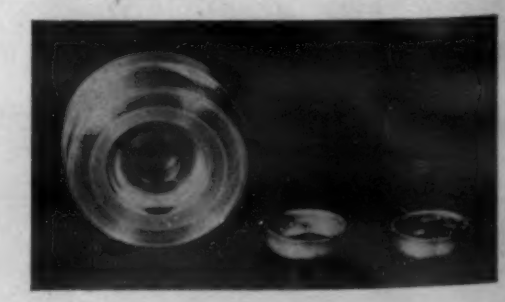


It has already been adopted by two exhibitors at the New York World's Fair. It may be sprayed or brushed on by a simple technique.

Brass and Bronze Ingots

The Metal Reduction Corp., North Bergen, N. J., announces that it is now in production of brass and bronze ingots under the brand name of "MeRitingots". Complete laboratory facilities have been provided and both standard and special composition of guaranteed quality will be furnished. Martin J. Bernstein, formerly of R. Lavin & Sons, Chicago, and the Vulcan-Louisville Smelting Co., is in full charge of production.

Hand-Operated Plating Barrel Hoist



An improvement in plating barrel construction has recently been perfected in the form of the Mercil hand operated hoist for single cylinder plating barrels, made by the Hanson-Van Winkle-Munning Co., Matawan, N. J., manufacturers of electro-plating equipment and supplies. This type of hoist which is very simple and inexpensive, consists of an iron framework, on top of which are two brackets with bronze bushings carrying a 1¼-in. shaft. A ¼-in. wire cable is wound around this shaft, at one end of which is a ⅜-in. pitch, 36-tooth sprocket connected to a 12-tooth sprocket at the lower end, with a ⅝-in. pitch roller chain. The 12-tooth sprocket is mounted in a 1¼-in. shaft which carries the ratchet and crank handle and also runs in a bronze bearing. It is possible to reverse the position of the crank handle to the opposite side of the tank as the parts involved are removable and arranged for assembly on either side of the framework. There is a 3 to 1 ratio which requires about 15 turns to lift a 14-in. diameter barrel and about 17 turns for lifting a 20-in. barrel.

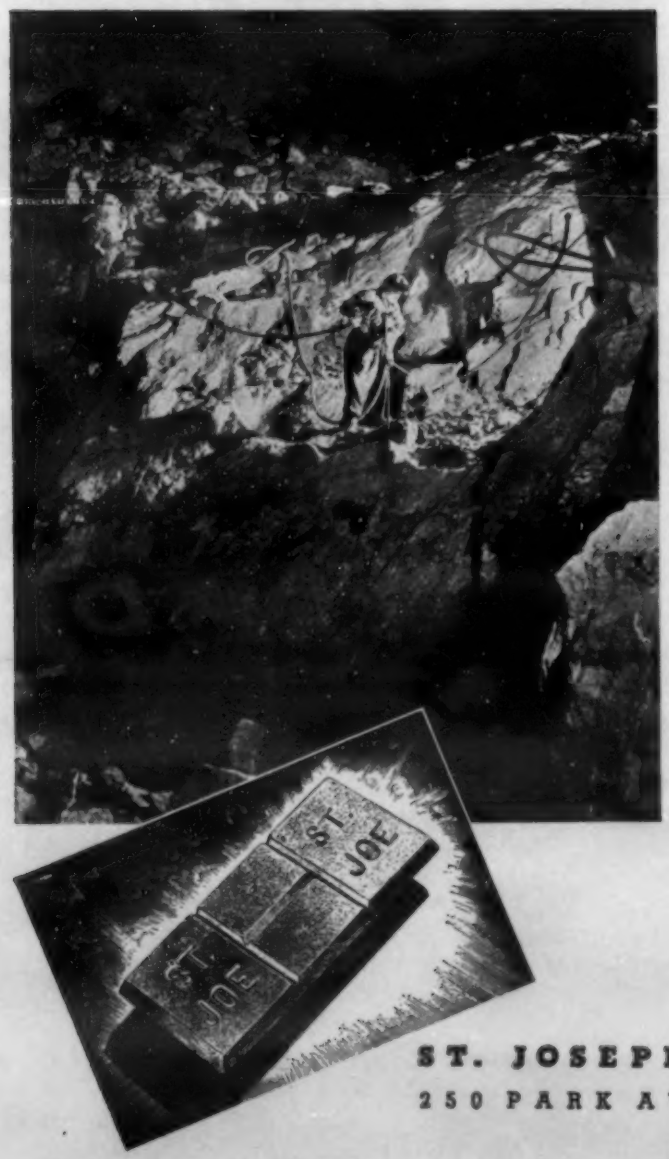
Carbide Inserts for Dies

A new hard carbide insert for dies used in stamping and drawing automobile parts, chair casters, bottle caps, cans, electrical appliances, wire and other metal products for home and industrial use, has been announced by McKenna Metals Co., 158 Lloyd Ave., Latrobe, Pa. Recent tests conducted by a large caster manufacturer are said to indicate that dies faced with the new material, known as Kennametal, will outlast ordinary tool steel dies many times.

In regular production runs Kennametal-faced dies stamped out 70,000 chair centers before the first regrind, as compared with a total life of 14,000 pieces for the best tool steel die they had been using. While this represents an increase of 500 per cent in the number of pieces turned out, Kennametal-faced dies actually have an even greater advantage, for they may be reground several times before being discarded. The die in the illustration has stamped out 11,000 casters without any visible sign of wear. The basic ingredient of Kennametal alloys is an intermetallic compound of tungsten-titanium carbide, corresponding to the formula WTiC2.

FROM ORE TO METAL

The Story of St. Joe Electro-Thermic Zinc—Number 3 of a Series



THE DRILLMAN

One of the key men in mining is the drill runner, with a keen eye for pay ore, a strong arm for controlling his throbbing machine, and an experienced knowledge for the proper placing of holes to ensure the maximum rock tonnage broken for the minimum of time and dynamite consumed.

Two hoses connect with his drill, one for the compressed air for power, the other supplying dust-preventing water.

He works 500 to 2,000 feet underground in a temperature of 60° F. On the surface it may be a stifling summer day, or 35° below zero, as it was one morning in January 1939.

He drills, loads his holes and fires (blasts) them, in the Edwards and Balmat zinc mines of the St. Joseph Lead Company in northern New York State. From here the concentrates are shipped to the Company's smelter at Josephtown, Pa., for conversion into the new electrothermic Highgrade, Intermediate and Prime Western grades of St. Joe Zinc.

ELdorado 5-3200

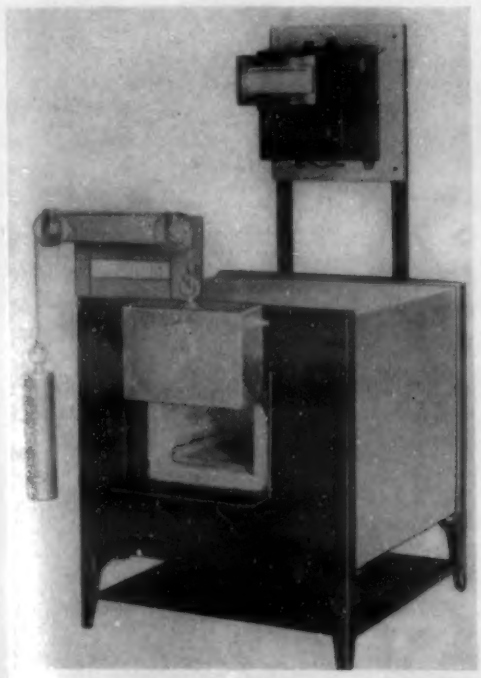
PLANT AND LABORATORY, JOSEPHTOWN, BEAVER COUNTY, PENNSYLVANIA

Small Heat-Treating Furnace

A furnace known as "Type MI-3" and offered by the Cooley Electric Mfg Corp., Indianapolis, Ind., is designed for application to a littie more severe service than is expected of laboratory muffle furnaces. It is well suited for heat treating small parts and can be operated at 1750°F. continuously and 1850°F. intermittently.

The furnace is unusually heavily insulated, and incorporates a cast iron door and a cast nickel-chromium hearth plate. Chamber size is 7⅜x5¼-in. It is extremely rugged and durable. It is supplied with 3400 watts at 220 volts, single phase,, a.c. or d.c. and can be furnished either with or without the pyrometer.

When it is desirable from the type of operation, this furnace can be equipped with a heating unit in the door to furnish additional heat at this point. Working dimensions of the chamber are 6¾ in. wide by 5 in. high by 14 in. deep.



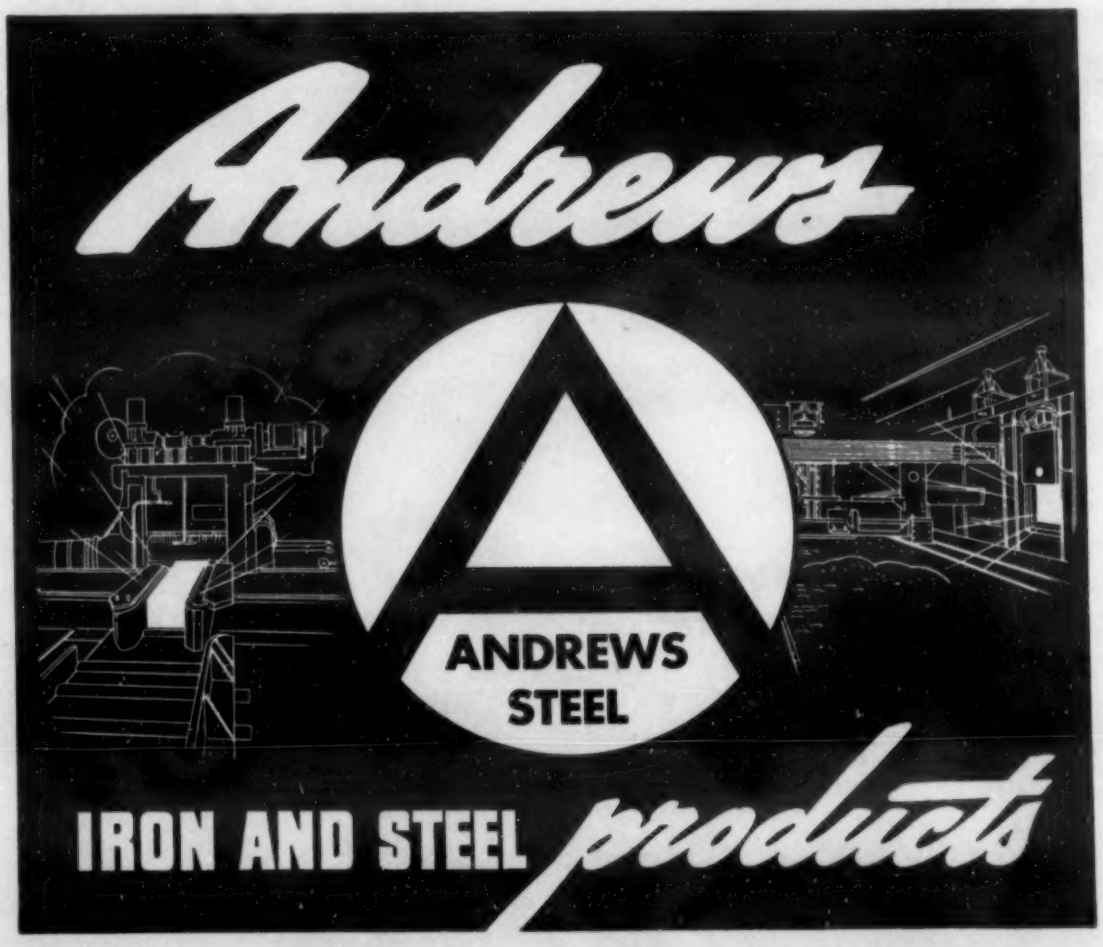
Moly Briquettes

Molybdic oxide briquettes are composed of a mixture of technical molybdenum trioxide and a sulphur-free pitch binder, briquetted under hydraulic pressure. The proportions of the molybdenum trioxide and the carbon in the binder are such that the briquettes are completely self-reducing.

The Climax Molybdenum Co., 500 Fifth Ave., New York, has developed and patented these briquettes both in this country and abroad with the idea originally of providing an economical and convenient means of making molybdenum additions to cast iron, either in the cupola, or in electric or air furnaces. However, it was soon discovered that they also have practical advantages as a means of adding molybdenum to steel.

The briquettes are cylindrical, being about 3½ in. in diameter by 4½ in. long, and weighing about 5 ibs. Although the molybdenum content of the material may vary, adjustments in size and weight are made so that every briquette contains exactly 2½ lbs. of metallic molybdenum. They are packed in cartons, four to the carton, thus each carton contains 10 lbs. of metallic molybdenum.

These briquettes are being used under ordinary working conditions to produce iron containing molybdenum in desired percentages up to 2 per cent. They are also being used to produce molybdenum steels of various types. In both cases recoveries are in the order of 95 to 100 per cent. There is no carbon pick-up in either case. Concerning the composition of the new briquettes and the methods of using them, these factors are covered in considerable detail in a pamphlet which is available to anyone interested in obtaining complete information.



Detects Pinholes in Sheet Metal

Holes as small as one-third the size of a pinhole are detected in a yard-wide ribbon of thin sheet steel racing from an ultra-modern sheet mill through a machine at speeds up to 1000 ft. per min. A row of phototubes ceaselessly scans the sheet for holes, and makes a conspicuous mark by each. In a minute sufficient sheet is scanned by this new Westinghouse device to make 5,000 cans for soup, milk or beer.

Inspection of tin-plate steel for holes has been a troublesome problem. In rolling steel to almost paper thinness, some thin spots and small holes are inevitable. Some holes are almost too small to be seen, yet are too large to be covered over in the eventual tinning process. Cans containing holes mean not only loss of the product canned, but possible damage to other goods in shipment.

Not alone feasible for steel sheet, the "pinhole" detector may be used for other materials such as metals, plastics, or opaque materials, such as rubber-coated cloth.

After all, steel making at its best is a precision art in which the most important factor is man power. There's a knack to steel making that only the years can bring and only long experience sharpen. Here at Andrews we pride ourselves on our men and their superior steel making abilities. Every slab, bar, bloom or billet that leaves this plant bears the unmistakable imprint of each man's skill and craftsmanship. To select Andrews for your requirements is to make sure of two major essentials: (1) iron and steel products of unsurpassed quality, and (2) a wholly dependable source of supply.

In Carbon and Alloy Steels: Blooms • Forging Billets • Rerolling Billets • Slabs • Universal Mill Plates • Sheet Bars

Small Arc Welder with Self-Indicating Dual Continuous Control

A small motor-generator type arc welder, said to provide greater convenience and accuracy in welding because of a new self-indicating dual continuous current control, is announced by The Lincoln Electric Co., Cleveland. Because of its advanced features and moderate price, this unit is expected to widen the application of welding in new fields such as garages, bus and truck fleet repair shops, sheet metal shops, and so on.

The welder, known as the "SA-150", has both job selector and current control calibrated and equipped with dials which indicate the type of work and number of amperes for each and every setting. It is claimed that this development enables the welding operator to secure highest quality welds and highest possible welding speeds

because he can vary both the slope of the volt-ampere curve and the amount of welding current independently and positively to suit every job encountered.

The SA-150, despite its moderate size, has a large number of welding applications within its scope. At the lower part of its range, the welder delivers a current of light-penetration characteristics for the welding of extremely light-gauge material. At the upper portion of its range it delivers ample current for the speedy welding of heavier materials. Complete absence of inflammable materials, such as cotton, linen, fiber, wood, bakelite, etc., enables the machine to withstand sustained operation under overload conditions. Connections are readily accessible for either 220 or 440 volts, 3 or 2-phase, 60 or 50 cycles as desired; the machine can be supplied for 550 volts or special voltages.

The new welder's self-indicating dual continuous control, available for the first time in so small a unit, its uniform welding current of high responsiveness for a speedy welding of all metals and alloys, make the SA-150 an ideal unit for installations where handy portability and versatility are requisite. Increased use of welding has also been furthered by making available similar machines in 75 and 100 ampere sizes.

Electrode for Transformer Welders

A new arc welding electrode for use with alternating current transformer type welders which have low open circuit voltage is announced by The Lincoln Electric Co., Cleveland. The new electrode, known as "Readyweld", is a low-carbon steel rod with a heavy extruded shielded arc coating possessing properties which assure arc stability and easy re-striking of the arc with small low-voltage transformer welders.

Readyweld is intended for general welding and repair work on light gage sheet steel. The electrode provides weld metal which possesses high strength and ductility. Because of its desirable arc characteristics, the electrode is said to permit easier and better welding in the type of work for which it has been developed.

Although designed primarily for use with alternating current transformer welders of low open-circuit voltage, Readyweld also operates well with direct current negative plants. The electrode is manufactured in 3/32 in. dia.. 12-in. lengths, packed in 25-lb. containers.

Portable Automatic Gas Analyzer

To meet an insistent demand for a gas analyzer that anybody could use, that would stand transporting and possible rough handling and that yet would be sufficiently accurate for all practical test purposes, the Orsatomat has been developed by the Hays Corp., Michigan City, Ind. It is said to be ideal for traveling installation and service engineers and for general gas analysis—for example, of heat-treating atmospheres—at separated points around a plant.

The Orsatomat is described as a thoroughly reliable Orsat type of gas analyzer, revolutionary in design and without fragile glass parts to break or intricate mechanical or electrical parts to clog or get out of order. Unlike the usual type of Orsat the Orsatomat requires no valve manipulation, no leveling, no burette readings. To simple movements of a rod are all that is necessary to secure an analysis—the result is indicated by the position of a needle on a large, legible scale.

Two models are offered—one for CO_2 only, another for CO_2 and O_2. A special model is also offered for use in the automotive field for testing exhaust gases. Flue gas models may be had with draft and temperature measuring elements.

The Hays Orsatomat is a true Orsat as it adheres strictly to the principle of volumetric measurement and chemical absorption. The sample of gas to be analyzed is aspirated from a point in the line to the measuring chamber by means of an aspirator bulb. When sample has been secured, a rod is pushed down, causing the analyzing body to tilt. As the analyzing body is tilted, mercury flows from a reservoir into the measuring chamber, displacing the sample and forcing it into the absorption chamber, which is filled with metal wool saturated with Cardisorber (a CO_2 absorbing chemical). Here the CO_2 in the gas sample is absorbed, causing a vacuum through the shrinkage in volume. This vacuum or suction is transmitted through metallic bellows to a large pointer which indicates the CO_2 percentage on the scale at the front of the instrument. The same dial has a scale showing draft measurement in inches of water.

Metallographic Cleaner

A new metallographic cleaner has been developed by The Enthone Co., 442 Elm St., New Haven, Conn., which is claimed to assist in preparation of scratch-free metal specimens for microscopic examination. The cleaner is said to be a liquid with high penetrating power which will wet and remove solid particles of abrasive or metal particles formed during the polishing of the specimens. The liquid is self-emulsifying and can be completely rinsed in cold water carrying off all solid particles leaving a clean, dirt-free surface.

The cleaner is also used to wash the polishing cloths removing all particles of dust, minute metal chips or abrasive thus avoiding all danger of scratches in the metallographic specimens from these sources and preventing the cloths from smearing or loading. The metallographic cleaner is particularly valuable for cleaning metallographic specimens being polished on emery papers using kerosene or paraffin as a lubricant. The cleaner penetrates these lubricants and when washed off in water will carry off the lubricant and all solid dirt.

Inasmuch as the presence of only a few coarse particles will spoil the most careful workmanship in metallographic polishing, soap and plain water rinsing have been found inadequate because of their inability to remove all solid particles from the specimens being polished, the polishing cloth discs, or the operator's hands.

"Enthone Metallographic Cleaner" is claimed by the manufacturer to have proved its ability on practical trials to insure perfect preparation of metallographic specimens. The cleaner has no etching action on metals including magnesium, aluminum, zinc, copper, iron or their alloys. It is used simply by brushing it on the specimens or squirting it on with an oil can and then rinsing in running water which is said to remove the cleaner and all solid dirt.

Portable X-Ray Machine

The latest weapon in the inevitably victorious campaign against flaws in industrial products, a 220-kv portable X-ray flaw detector was recently placed in service in examining structural welds and heavy castings on production lines at the East Pittsburgh works of the Westinghouse Electric & Mfg. Co.

The technique of radiographic diagnosis of large steel parts is expected to be much simplified by this 4500-lb. portable X-ray camera, since it may be wheeled along production lines to maintain the quality of machines during their manufacture.

Shockproof, completely self-contained, ready for work wherever there is a proper power supply, it generates X-rays with a penetrating quality sufficient for them to pass through 3 in. of solid steel. The focusing mechanism on the new equipment is extremely flexible, so that the apparatus may be aimed at a weld or casting in either a horizontal or vertical position.

X-ray tube, transformer, capacitors, and flexible focusing device are all compactly mounted on a chassis with four balloon tires, automobile springs, and two-wheel mechanical brakes, enabling two men to move the apparatus in safety.

"Magnilite"—Daylight Plus Magnification

The "Magnilite", developed by Mizzy, Inc., 105 East 16th St., New York City, designed for tool and die makers and machinists, is said to be also the perfect, practical solution for many inspection problems in the factory, as it is detachable from stand and can be used in any given position. The new light concentrates pure daylight rays on the object being inspected which in turn is viewed under magnification from above. Inspection efficiency is substantially increased, caliper readings more easily determined, and eye strain is eliminated. The Magnilite is attached to the base on a universal joint and permits adjustment into any desired position.

JOHN ATTWOOD, SECTION EDITOR

Some Studies on the Gold-dissolution Rate in Cyanide Solutions. A. W. FAHRENWALD & JOS. NEWTON (Univ. Idaho) *Eng. Mining J.*, Vol. 140, Jan. 1939, pp. 44-46, 47. The effect of certain variables are studied in a series of experiments. These studies are discussed from the following angles: (1) The effect of simultaneous variation of cyanide and O content on the dissolution of Au from Au foil; (2) the effect of varying O pressure on the dissolution of Au from siliceous Au ores; and (3) the effect of various alkalies on the rate of dissolution of Au from a siliceous ore. Conclusions drawn from the present investigation are: (1) the rate of dissolution of Au from Au foil is directly proportional to the pressure of the O, provided the cyanide strength of the solution is increased in the same ratio as the O pressure; (2) the rate of dissolution of Au from Au ore does not increase in proportion to the O pressure in solutions of constant cyanide strength, but it tends to increase rapidly at first, reach a maximum and then diminish again; (3) as a rule, the cyanide loss tends to decrease at first and then rise again; and (4) the effects of caustic soda, soda ash and sodium phosphate on the extraction are all about the same, while lime and sodium sulphide decrease the rate of dissolution very markedly. The pH cannot be the principal factor that causes the decrease in solution rate; also, cyanide loss and rate of dissolution are not directly connected. WHB (1)

Gold Mining and Milling in Idaho County, Idaho. S. H. LORAIN. *U. S. Bur. Mines Information Circ.* No. 7039, Dec. 1938, 90 pp. At the Lone Pine mine, Au recovery up to 1937 was 97% by amalgamation, using an unusual flow sheet. Costs were $4.114/ton. At the Orogrande-Friscoe mine, sands are leached and slimes agitated in a straight cyanidation circuit giving 80-83% recovery at a cost of $0.3181/ton. At the Gnome mine, 91-92% recovery was secured by straight cyanidation of the oxidized ore; this dropped to 80% when the unoxidized ore was reached. Costs were $3.84/ton. At the Mammoth mine, the ore is floated in a new mill using Barrett No. 4 oil and pine oil (90-10% mixture) in the ball mill and ethyl xanthate and soap reagent in the rougher cells. At the Robinson mine, the ore passes over a blanket table to flotation. After a light roast, concentrates are cyanided. Extraction is 98%. At the Golden Anchor mill, recovery by amalgamation of jig and table concentrates is 75. 64% by flotation 17.39% more—93% in all. Costs are $2.70/ton. At the Snowshoe mill, a flotation concentrate is produced containing $200 of Au/ton. Flow sheets and metallurgical details are given for the foregoing. Many other mills are described briefly. See *Metals and Alloys*, Vol. 9, Dec. 1938, p. MA 700 L/5. AHE (1)

Copper and Antimony in Cyanidation. M. W. VON BERNEWITZ. *U. S. Bur. Mines, Rept. of Investigations* No. 3425, Dec. 1938, pp. 25-28. Ores containing up to 0.5% Cu soluble in cyanide may be treated with NaCN in acid solution without high cyanide consumption; 80% of the cyanide used in dissolution of Cu can be regenerated. Use of strong cyanide solution or addition of soluble Pb salts prevents deposition of Cu on Zn shavings. There is no problem from Cu precipitation if Zn dust is used. Excess Cu in the precipitate may be reduced to 4% by treatment with hot H_2SO_4 and MnO_2. Crude bullion may be refined by blowing air over the surface or by chlorination of the molten metal. Some ores containing stibnite respond favorably to a rapid roast at 810° F. and the addition of CaO to the calcine with a 3-day conditioning, followed by cyanidation. Flotation followed by roasting and cyanidation has given even better results. Tailings containing stibnite and Au respond to cyanidation when a suitable amount of air-slaked lime was used for neutralization. AHE (1)

Ore-testing Studies: Precious-metals Section. E. S. LEAVER & STAFF. *U. S. Bur. Mines Dept. of Investigations* No. 3425, Dec. 1938, pp. 43-83. Details of concentration and extraction tests on the following are reported: Au ore from Ga., Ala., Id., S. D., Ore. and Nev.; Au-Ag ore from Mont., Utah, Id., Calif. and Nev.; Au-Ag-Pb ore from Mont.; Pb-Ag ore from Nev.; Ag-Pb-Zn ore from Colo.; Au-Ag-Cu ore from Mont.; and W ore from Nev. AHE (1)

The Microscope in Ore Testing. R. E. HEAD. *U. S. Bur. Mines Rept. of Investigations* No. 3425, Dec. 1938, pp. 7-14. Microscopic examination serves as an important complement to chemical analysis in interpreting the percentage composition of an ore in terms of minerals. If an ore is difficult to treat, reasons therefore and indicated procedures to overcome the trouble may be ascertained microscopically. Failures in flotation in 4 cases have been traced to (a) intensely intimate mineral association and (b) changes in normal mineral floatability due to the action of products of incipient oxidation. Surface stains and tarnish and the presence of adhering slime particles have been found to be responsible for the difficulty experienced in the treatment of certain Au ores. AHE (1)

Treatment of Arsenical Gold Ores. J. A. WOOLF & T. A. JACKSON. *U. S. Bur. Mines Rept. of Investigations* No. 3425, Dec. 1938, pp. 15-24. Descriptive. Most arsenical Au ores do not respond to simple treatments such as flotation, amalgamation, direct cyanidation, or a combination thereof. Treatment methods include: (1) Low temperature (550° or less), (2) high temperature (600°-725°) oxidizing roast followed by cyanidation of the calcine, (3) preliminary treatment of the calcines from the high temperature oxidizing roast with weak H_2SO_4 solution followed by cyanidation of the residue, (4) a partial sulphating roast followed by cyanidation either direct or preceded by H_2O wash, and (5) fine grinding and flotation followed by roasting of the tailing and direct cyanidation of the calcine. Recent Results in Magnetic Roasting of Brown Clay Iron Ores (Neue Ergebnisse bei der magnetischen Röstung von Brauneisenerzen) W. LUYKEN & G. KREMER. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch., Düsseldorf*, Vol. 20, No. 21, 1938, pp. 292-301. Research. A report is made on the results of roasting Fe-poor ores of different origin, which, besides 23.9-24.6% Fe, contained 28-56% SiO_2 and 3-11% Al_2O_3 and smaller percentages of Mn, CaO, MgO, CO_2. The roasting process increased the Fe content in the concentrate to 49.6%, and the yield of Fe was 86%. A special advantage of the roasting process was that 18-28% of the As content was driven off; the subsequent magnetic separation removed about 24% more. 5 references. Ha (1)

Ore-testing Studies: Ore-dressing Section. A. L. ENGEL & MORRIS GUGGENHEIM. *U. S. Bur. Mines Rept. of Investigations* No. 3425, Dec. 1938, pp. 85-104. Details of concentration tests on the following ores are reported: Sn from S. D. and Nev.; Mn from Texas and the Philippine Islands; Ti from Nev. and Ark.; barite from Mo. and Calif.; kyanite from Nev. and Ariz.; feldspar from S.D., N. H. and Conn.; fluorspar from Ky.; Pb-Zn-fluorspar from Ill. and Ky.; pyrite in coal-mine waste from Ill.; a sulphide ore from Calif.; and Cu from the Philippine Islands. See also *Metals and Alloys*, Vol. 8, July 1937, p. MA 408L/2. AHE (1)

Chlorination of Lean Oxidized Nickel Ores by Elementary Chlorine. A. E. BERDNIKOV. *Tsvetnye Metall.*, No. 9, Sept. 1938, pp. 91-94. In Russian. Research. Laboratory experiments showed the feasibility of extraction of Ni from oxidized ores containing 1% Ni or less. The recovery of 78 to 82% of the Ni is possible. The consumption of reducer (coal or charcoal) is equal to 20-25% of the weight of the ore. If Co is present in the ore, it is converted to chloride, together with the Ni, and can be easily separated from the solution. Only 3 or 4% of the Ural Ni ores (with Ni content above 1%) can be extracted by pyrometallurgical methods; the chlorination method is, therefore, of great promise in the treatment of the lean Ni ores. BND (1)

Treatment of Mill Water for Flotation. A. L. ENGEL & MORRIS GUGGENHEIM. *U. S. Bur. Mines Rept. of Investigations* No. 3425, Dec. 1938, pp. 29-31. Not only is it necessary to remove excess soluble salts from mill water by chemical treatment, but the H-ion concentration may also have to be adjusted to effect the desired separation. Treatment must counteract soluble salts in water, salts dissolved from ore, and Fe salts introduced in grinding with Fe balls. A specific case involving flotation of descloizite is described. Fundamentals of the Production of High-manganese Slags from Spiegeleisen and Phosphorus-spiegeleisen (Unterlagen zur Gewinnung manganreicher Schlacken aus Spiegeleisen und Phosphorspielgeleisen) W. OELSEN. *Stahl u. Eisen,* Vol. 59, Jan. 26, 1939, pp. 81-87. Original research. Open-hearth slags can be smelted in the blast furnace to give a P spiegel with about 16% Mn and 2% P. From such high-C spiegel, a Mn-rich slag can in turn be produced by oxidation. Various oxidation methods were studied using small melts. Experiments with the slagging of Mn by additions of FeS at temperatures above 1600° C. are described. The effect of Mn and S in the bath on the Mn:Fe ratio in the slag is shown by graphs. As the Mn in the bath goes up to 2%, the Mn in the slag increases rapidly. When treating spiegel with oxide-sulphide mixes, the Si is naturally slagged before the Mn so that the ratio SiO_2:Mn in the slag is determined by the Si:Mn ratio in the spiegel. Because of the strong fluxing action of SiO_2 on MnO, less sulphide goes to the slag as the SiO_2 increases. Without sulphide additions, and by using SiO_2 as a flux at 1350°-1450° C., Mn-rich slags with fairly low SiO_2:Mn can be obtained. This is especially important in obtaining Mn-rich slags from Si-rich spiegel. In low-Si spiegel, the fluxing of the slag, in the absence of SiO_2, can be accomplished by the addition of Fe-Mn ores high in SiO_2. For obtaining Mn-rich slags from P spiegel, the behavior of P during the oxidation of Mn was studied. The oxidation of P decreases with increasing Mn content of the bath and also with increasing sulphide and SiO_2 content of the slag. By slagging Mn in stages, a more favorable Mn:Fe ratio in the slag was obtained, and with P spiegel a lower slagging of P. The effect of such oxidation agents as $CaSO_4$, Na_2SO_4, $FeSO_4$ and $BaSO_4$ is also discussed SE (2a) 6

Reduction of Iron Ores under Pressure by Hydrogen. MICHAEL TENENBAUM & T. L. JOSEPH (Univ. Minn.) *Metals Tech.,* Vol. 6, Jan. 1939, T.P. No. 1011, 13 pp. Original research. A number of cubes of Fe ore were reduced by H under comparable conditions at several pressures. Pressures greater than 10 in. of Hg materially increased the rate of reduction. This increased reaction velocity was not so great at 600° or 700° C. as it was at 800° C. Both of these results are in agreement with conclusions reached from theoretical considerations given in the paper. JLG (2a) 7

Construction of Modern Blast Furnace Stoves (Construction des Appareils "Cowper" Modernes) D. PETIT. *Rev. Mét.,* Vol. 35, Nov. 1938, pp. 477-494; Dec. 1938, pp. 544-561. A very detailed discussion is given of the construction of blast furnace stoves. The types are: (1) Constant section, such as Cockerill, which is most used in Europe with tubes fitted into each other; (2) zoned stoves with circular, hexagonal, square (or square with divisions, such as Brassert) sections; (3) turbulent, such as Wabenstein, used in Germany. Refractories are used more than castings, since the former have lower cost and weight, although the latter give more rapid heat transfer. JZB (2a) 8

Inland Steel Co. Honors Founders in Lighting 1000-ton Blast Furnace. *Iron Age,* Vol. 143, Jan. 12, 1939, pp. 40-41. Description of a new blast furnace. Unusual feature is the crank action of operating bell mechanism instead of the conventional bell beam. Stoves are 26 ft. in diameter and 110 ft. high. Each stove has about 200,000 sq. ft. of heating surface and 50 sq. ft. of combustion chamber. Freyn burners use 22,500 cu. ft. of gas/min. The stack has 14 tuyeres and 7 columns, and the hearth diameter is 25 ft. VSP (2a) 9

Combustion in the Atmosphere of Surplus Blast Furnace Gas in Metallurgical Factories (La Combustion dans l'Atmosphère des Excédents de Gaz de Hauts-Fourneaux dans les Usines Métallurgiques) L. POUPET & R. CHAURAND. *Rev. Mét.,* Vol. 35, Dec. 1938, pp. 525-530. Practical. French law prohibits release of blast furnace gas with over 1.5-2 g./cm. dust and over 1% CO. Surplus gas (refined to meet the above requirements) was burned in large automatic burners at Acieries de Longwy. JZB (2a) 10

The Thermal Reduction of Roasted Zinc Sulfide and the Condensation of Zinc (Untersuchungen über die thermische Reduktion von Röstblende und die Kondensation von Zink) G. GRILLO. *Metall u. Erz,* Vol. 35, No. 18, 1938, pp. 475-480. Research. The historical development of practice, theories of reduction of Zn blende and the effects of pretreatment of ZnO, of reducing agents and of the physical condition of the material are discussed. The extent to which the efficiency of the Zn muffle is affected by different reducing agents and different degrees of roasting was determined. Cheap coal can be used for reduction without significant difference in yield. Too heavy airing of the condenser chamber lowered the yield, owing to deposition on the walls, and too high a temperature gave oxidation losses. The condenser should be long enough to permit gradual cooling in a large condensation space, yet it must not permit the metal to solidify. A change of wall thickness had a negligible effect on the yield. The greater part of the metal in the vapors is condensed as soon as the gases have cooled below the dew point of the Zn. In order to obtain the remainder in liquid drops, the gases should cool very gradually with very slow flow along (preferably) heated baffles. The dimensions and arrangement of the furnace are, however, of great importance, as is shown by construction details. PCR + Ha (2b) 3 4 5

Zinc Vapor Condensation in Vertical Muffles (Die Zinkdampfverdichtung bei stehenden Muffeln) A. RITZHEIM. *Metall u. Erz,* Vol. 35, No. 20, 1938, pp. 531-539. Research. Owing to the CO_2 formed in Zn ore reduction and carried over to the condenser, a certain amount of oxidation of the Zn vapor occurs. An easily reduced Zn ore reacts with CO to produce CO_2 faster than the CO_2 can be reduced back to CO by C, resulting in a higher concentration of CO_2 in the condenser than with a difficultly reducible ore. Adding more gas to the charge increases the reaction rate without increasing the CO content, which can only be affected by raising the temperature. This, however, affects the surface of the ore and results in increased ZnO and Zn dust. By using a continuous process in a vertical muffle, the gases must pass up through the colder parts of the charge where the ZnO precipitates, and the remaining gases containing Zn vapor continue to the condenser. The use of the continuous process eliminates congestion that might occur from the ZnO precipitate. PCR (2b) 6 7

Electrolytic Parting of Gold and Silver, at the Works of the Broken Hill Associated Smelters Pty., Ltd., Port Pirie. F. A. GREEN. *Proc. Australasian Inst. Mining Met.,* No. 107, Sept. 30, 1937, pp. 205-221. The layout, equipment and operating details are described. The electrolyte is a neutral solution of $AgNO_3$ containing 200 g. Ag/l. Ag from the anode plates is deposited on cathode carbons in fine granular form. Ag is raked out every 4 hrs. The anode sludge is melted to a high grade doré bullion that is parted to give a final Au sludge. This is treated with HNO_3 melted, cast, remelted and refined with Cl. AHE (2b) 8

The Production of Zinc from Zinc Dust through Melting, with Special Reference to the Thede Process (Die Gewinnung von Zink aus Zinkstaub durch Asschmelzen, insbesondere nach dem Thede-Verfahren) J. J. THEDE. *Metall u. Erz,* Vol. 35, No. 12, 1938, pp. 317-321. Descriptive. Zn dust is treated in a rotating externally-heated closed drum kept above the melting point of Zn. The yield is about 95% and the cost about 1/10 that of the distillation process. Economic considerations are discussed. PCR (2b) 9

The Influence of the Crystalline Structure of Bauxite on Its Decomposition in the Bayer Process (Der Einfluss der Kristallinen Struktur der Bauxit auf ihre Aufschliessbarkeit nach dem Bayer-Verfahren) ALBERT ROTH. *Metall u. Erz,* Vol. 35, No. 17, 1938, pp. 447-450. Original research. Ores having a low yield contained a correspondingly high diaspore content as shown by the Debye-Scherrer method. The lengthy and costly preliminary tests to determine their yield can be eliminated by using X-ray tests. PCR (2b) 10

3·MELTING, REFINING AND CASTING

Direct and Continuous Casting Production of Sheet and Bar from Molten Metal. E. R. MORT. *Metal Ind., London,* Vol. 54, Jan. 13, 1939, pp. 41-46. Up-to-date review. The production of sheet, rod, tube and strip direct from the molten metal has several very obvious advantages from the economic viewpoint. Attention was first drawn to the method as far back as 1846, when Bessemer patented such a process. Little note was taken of its possibilities until 7 yrs. ago, when Hazelett and Eldred began their work. Two types of processes have been developed, one that manufactures a salable product direct from the molten metal, known as "direct casting," and another that manufactures in indefinite lengths something intermediate between the raw material and the finished product, known as "continuous casting." The *Hazelett process,* a direct casting method, is little different from Bessemer's original idea; in it the molten metal is poured so as to form a lake above the nip of the rolls, which are water cooled. The pouring temperature, diameter and speed of the rolls are critical factors. Three difficulties are encountered: Preferential solidification of the metal on the flanges of the roll, segregation in alloys, and oxidation. At present the process is being used for Pb and Al in strip form. Al strip so produced has a tensile strength of 14,000 lbs./in.^{2} with good ductility. Foil can be produced much more cheaply from this strip than is possible with the conventional method. A great deal of development work has also been carried out on the direct rolling of brass, as yet without success. The process is not at the moment sufficiently advanced to render it a commercial proposition, except under special circumstances. The Hazelett process is confined to the production of strip. The *Eldred process* is especially suitable for the production of wire and rod. The metal is melted in a furnace, in the bottom of which are a number of chambers; beneath them are a die and cooling chamber. Operations are started by inserting a rod into the forming chamber; molten metal congeals on the rod and is drawn through the die. Another continuous process, developed by Kohlhass, is described, but is not being used commercially. Emphasis is placed on the ability to exclude air from the casting groove so that the molten metal is solidified without undue exposure to the atmosphere. The Jungham process is in commercial use. The molten metal is fed through a nozzle into a moving, open, watercooled mold. By accurate control of the speed at which the various parts of the system operate, and by arranging suitable cooling conditions, it is possible to produce a section of infinite length; therefore, the process is of the "continuous" type. Numerous other processes have been offered but few have been tried on a commercial scale. Billets of continuously cast Cu are available in America. The only claims made for these billets are that they are available in any length and have a much superior surface as compared with the ordinary commercial product. The process is apparently operated so as to produce a grain structure as nearly as possible similar to the normal cast structure. RWB (3)

Compression Strength and Shearing Strength of Moulding Sand. B. HOLMAN. *Foundry Trade J.,* Vol. 59, Dec. 8, 1938, pp. 429-431. Original research. Comparison tests were made with 14 types of molding sand of widely varying qualities. The specimens for testing the compression and the shearing strengths are identical in shape, being cylindrical and having a mean height of 2 in. Three specimens were employed in the green state for the cohesion test by determining the compression strength. The tests were made in the Adams apparatus. The other 3 specimens were used for the cohesion tests by determining the shearing strength in the Dietert balance beam apparatus. The following conclusions were reached: (1) The shearing strength is much lower than the compression strength; (2) the reciprocal comparison of the cohesion of the various types of sand is practically the same, whether cohesion is determined on the basis of the compression strength or of the shearing strength; (3) the compression or shearing strength of the green specimens depends in the same way upon the moisture content, *i.e.* both the compression strength and shearing strength diminish with increasing moisture content of the sand; and (4) the compression strength and the shearing strength of the baked specimens increase with increasing moisture content of the specimens when rammed. AIK (3)

Present Status of Molding in Sand Mixed with Cement (Ou en est le Moulage en Sable Aggloméré au Ciment?) *Rev. Fonderie Moderne,* Vol. 32, Nov. 10/25, 1938, pp. 279-283. Review. Development of molding in sand-cement mixtures and present use, especially in France, is described. The greatest disadvantage of the method is the need to allow at least 24-48 hrs. for setting, which is inconvenient, especially for small pieces. The advantages of the method are suppression of heating of the mold and thus lower fuel consumption, better production of castings and simplification of molding owing to greater strength of the material so that supports become less necessary, less danger of scratching and defacing of the molds. The recommended composition is 70% of a siliceous sand (about 98.5% Si) of 60 mesh grain size and as free as possible of clay, 3-15% cement and 2-9% water, mixed together in any good mixer. Examples show molding methods; recovery of sand and preparation of mixtures is described. Ha (3)
